ENCYCLOPÆDIA BRITANNICA.

G O U — G O U

G O U D A, or **Ten Gouwe**, a town of the Netherlands in the province of South Holland, at the confluence of the Gouwe with the Yssel, 12 miles N E of Rotterdam, at the junction of the railway from that city with the line between the Hague and Utrecht. The town is for the most part laid out in an open and lightsome manner, and like the other towns of Holland is intersected by numerous canals. Portions of the old fortifications are changed into promenades, and the suburban quarters, Fluwelensingel, Bleekersingel, Kattousingel, and Turfsingel, are adorned with fine trees. The Grootte Markt is the largest market square in Holland. Among the churches—five of which are Protestant, two Roman Catholic, and one Old Catholic—the first place belongs to the church of St John (Janskerk), a building of the 16th century, which replaced an earlier structure of the 15th, and which is not only remarkable for its dimensions, 345 feet in length and 150 feet broad, but possesses a celebrated organ, and a series of splendid painted windows, several of which are the workmanship of Dijk and Wouter Krahth (1555–1603). (Compare *Explanation of the Fumous and Renowned Glass Work, &c.*, Gouda, 1876, reprinted from an older volume, 1718.) Of the other public buildings it is sufficient to mention the town-house, with a fine Gothic facade, founded in 1449, but rebuilt in 1690, the weigh-house, the house of correction for women, the gymnasium, St Catharine's hospital, and the music hall. A public library containing many rare and valuable works is kept in St John's church, and a municipal museum of antiquities was opened in 1874. In the time of the counts the wealth of Gouda was mainly derived from brewing and cloth weaving: about 1610, for example, the breweries numbered 166, and upwards of 1000 pieces of cloth were made in the course of the year, but at a later date the making of tobacco pipes became the staple trade, and in the middle of the 18th century gave employment to 3000 men. Though this industry has in turn declined, Gouda still possesses large pipe works and potteries, and among its other establishments are a celebrated manufactory of stearine candles, a yarn factory, an oil refinery, and sugar factories. It has also a good transit and shipping trade, and its market for cheese has made its name widely known throughout Europe. The population of the commune was, in 1796, 11,716, in 1830, 14,878, in 1860, 13,788, in

1860, 14,843, and in 1870, after a slight addition of area, 16,233. At the last date the town proper numbered 15,174 inhabitants. The greater proportion belong to the Dutch Reformed Church, but nearly 6000 are Roman Catholics. Gouda received its constitution as a town from Count Floris V in 1272. In 1332 it had only 820 houses, but it rapidly increased, and in the 14th century it was the fifth in size of the towns of Holland. The rise of Amsterdam made it only the sixth, but it retained this position till the revolution of 1795. The principal facts in its history are the attack by the people of Utrecht in 1488, the repulse of the Spaniards in 1574, the destruction of the castle of the lords of Gouda in 1577, the voluntary flooding of the surrounding country as a defence against the French in 1672, the great inundation of November 1775, and the riots of 1787.

GOUDIMEL, CLAUDE, composer of the 16th century, must be named amongst the founders of modern music. The French and the Belgians claim him as their countryman, and the place of his birth is not sufficiently established. In all probability, however, he was born at Vaison near Avignon, about the year 1510. As to his early education we know little or nothing, but the excellent Latin in which some of his letters were written prove that, in addition to his musical knowledge, he also acquired a good classical training. In 1540 we find him established in Rome at the head of a music-school, and here, amongst many other celebrated musicians, Palestrina, the greatest master of the early Italian school, and one of the greatest masters of all schools, was amongst his pupils. About the middle of the century he seems to have left Rome for Paris, where, in conjunction with Jean Duchesne, he published, in 1555, a setting of Horace's Odes, entitled, *Horati Flacc. odes omnes quatuor carminum generibus differunt ad lythmos muscos eductas*. Infinitely more important is another collection of vocal pieces, a setting of the celebrated French version of the Psalms by Marot and Beza (*Les Psalmes de David, mis en rime Françoise par Clement Marot et Théodore de Bèze, mis en musique par Claude Goudimel*), published in 1555. It is written in four parts, the melody being assigned to the tenor. Some of the tunes were probably of popular origin, and they are still used by the French Protestant Church. Others were adopted by the German

Lutherans, a German imitation of the French versions of the Psalms, in the same metres having been published at an early date. There is little doubt that, at the time of the last named composition, Gondimel had embraced the new faith, although the French version of the Psalms was at first used by Catholics as well as Protestants. Seven years later he fell a victim to religious fanaticism during the St Bartholomew massacres at Lyons (24th August 1572), his death, it is stated, being due to "les ennemis de la gloire de Dieu et quelques méchants envieux de l'honneur qu'il avoit acquis". In addition to the collections already named, many of his works are preserved. Masses and motets belonging to his Roman period are found in the Vatican library, and in the archives of various churches in Rome, and the archives of the various churches in Lyons, where they were published. Thus the work entitled *Messa à 4 voies à 4 Chœurs Gondimel protestantissimo maestro cantor e, nono pi unum in trece edite*, contains one mass by the Ismael edictor himself, the other two being by Claudius Semuy and Jean Maillat respectively. Another collection, *La fleur des chansons des durs plus excellens musiciens de nostre temps*, consists of part songs by Gondimel and Orlando di Lasso. Burney gives a motet of Gondimel's, *Domine quid multiplicasti vires*, in his history.

GOUGH, HUGH GOUGH, VISCOUNT (1770-1869), British field-marshal, was of Irish origin, and was a descendant of Francis Gough, who was made bishop of Limerick in 1698. He was born at Woodstock, Lancashire, November 3, 1770. After holding for a short time a commission in his father's regiment of militia, he was transferred to the line as ensign in August 1794, and was very soon after promoted lieutenant. In the following year he served with the 78th Highlanders at the Cape of Good Hope, taking part in the capture of Cape Town and of the Dutch fleet in Saldanha Bay. His next service was in the West Indies, where, with the 87th (Royal Irish Fusiliers), he shared in the attack on Porto Rico, the capture of San Juan, and the capture of San Juan. In 1809 he was called to take part in the Peninsular War, and, joining the army under Wellington, commanded his regiment as major in the operations before Oporto, by which the town was taken from the French. At Talavera he was severely wounded, and had his horse shot under him. For his conduct on this occasion he was afterwards promoted lieutenant colonel, his commission, on the recommendation of Wellington, being antedated from the day of the duke's despatch. He was then, as pointed out in *Lord's Army List*, the first officer who ever received brevet rank for services performed in the field at the head of a regiment. He was next engaged at the battle of Rossbach, in which his regiment captured a French eagle. As the defence of Tarris, the post of danger was assigned to him, and he compelled the enemy to raise the siege. At Vittoria, where Gough again distinguished himself, his regiment captured the baton of Marshal Jourdan. He was again severely wounded at Nivelle, and was soon after created a knight of St Charles by the king of Spain. In recognition of his services the citizens of Dublin presented him with the freedom of the city and with a costly sword. At the close of the war he returned home and enjoyed a respite of some years from active service. He next took command of a regiment stationed in the south of Ireland, discharging at the same time the duties of a magistrate during a period of agitation. Gough did not attain the rank of general officer till 1830, when he was promoted major-general. Seven years later a new epoch opened for him, as he was sent to India to take command of the Mysore division of the army. But not long after his arrival in India, the difficulties which had arisen between the Chinese and British Governments, and which led to the first Chinese war, made the presence of an energetic general

on the scene indispensable, and Gough was appointed commander in chief of the British forces in China. His post he held during all the operations of the war, and by his great achievements and numerous victories in the face of immense difficulties, he at length enabled the British plenipotentiary, Sir H. Pottinger, to dictate peace on his own terms, and on terms of perfect equality with the emperor. After the conclusion of the treaty of Nanking in August 1842 the British forces were withdrawn, and before the close of the year Gough was created a baronet, and was invested with the grand cross of the Bath. He also gave to the thanks of both Houses of Parliament. In 1843, when India, he was appointed (August 1843) commander in chief of the British forces in India. In December 1843 he took the command in person against the Afghans, and defeated them at Mahabadda, capturing most of their guns. He defeated them again at Pannier and Jellalabad, and then concluded at Gherat. In 1845 occurred the rupture with the Sikhs, who had the superiority in numbers, and Sir Hugh Gough conducted the operations against them. In this campaign he was well supported by Lord Hardinge, the governor-general who had been his comrade in the Peninsula, and now voluted not to serve under him. The Sikhs were defeated in three great battles in rapid succession at Moodkee, Ferozshah, and Chillianwallah, and submitted to the peace of Lahore. The services of Sir Hugh Gough in this campaign were rewarded by a vote of thanks from both Houses of Parliament, and by his elevation to the peerage of the United Kingdom as Baron Gough (April 1846). He was broke out again in 1848, and again Lord Gough took the field. With unmitigated energy he obtained the fall of Ranninggay, and at Chillianwallah, and finally by his power by his decisive victory at Cupra (February 1849). He was now succeeded as commander in chief of the British forces in India by Lord Dalhousie, and, returning to England, he was created a viscount, and, for the third time received the grand cross of the Order of the Bath. A year later he was granted a pension of £10,000 a year, and was created a baron of the United Kingdom. He did not return to India again. In 1851 he was appointed colonel of the Royal Artillery, and two years later he was created a knight of the Order of the Bath. His honours were multiplied up to the close of his later years. He was made a knight of the Order of the Bath, the first knight of the order who died in 1869. His Irish peerage, was sworn a peerage, and was created a knight grand commander of the Order of the Bath in November 1862 was made field-marshal. He was twice married, and left children by both his wives. He died at his seat near Dublin, March 2, 1869.

GOUGH, HENRY (1739-1809), an English antiquary, was the son of a wealthy East India doctor, and was born in London, October 1, 1737. He received his early education privately, and his literary talent developed with such precocity that, at the age of twelve and a half years, he had completed the translation of a history of the Bible from the French, which his mother printed for private circulation, at the age of fifteen he wrote a translation of Henry's work on the customs of the Jews, and at sixteen he had published an elaborate work entitled *The History of the Jews, or Geography under the Jews*. In 1752 he entered Benet College, Cambridge, where his fondness for antiquarian research received additional impulse, and which he commenced his work on British topography, which was published in 1768. After leaving Cambridge, in 1756, he began a series of antiquarian excavations in various parts of Great Britain, the fruit of which was seen in the volumes which he subsequently published. In 1773 he began to prepare an edition in English of Camden's *Britannia*, but

and the *Report on the Invertebrata* published by order of the legislature of Massachusetts in 1844. A second edition of the latter work was authorized in 1865, and published in 1870 after the author's death, which took place at Boston, September 18, 1866. Gould was an active member of the Boston Society of Natural History, and a corresponding member of all the prominent American scientific societies, and many of those of Europe, including the English Royal Society.

GOUR See GOUR

GOURD, a name given to various plants of the order Cucurbitaceæ, but more strictly applied to those belonging to the genus *Cucurbita*, monoecious climbing herbs of annual duration, with long succulent stems furnished with tendrils, and large, rough, palmately lobed leaves, the flowers, reticulated with veins, are generally large and of a bright yellow or orange colour, the barren ones with the stamens united, the fertile one followed by the large, succulent fruit that gives the gourds their chief economic value. Many varieties of *Cucurbita* are under cultivation in tropical and temperate climates, especially in southern Asia, but it is extremely difficult to refer them to definite specific groups, on account of the facility with which they hybridize, while it is very doubtful whether any of the original forms now exist in the wild state. M. Naudin, who made a careful and interesting series of observations upon this genus, came to the conclusion that all varieties known in European gardens might be referred to six original species, probably three, or at most four, have furnished the edible kinds in ordinary cultivation, and, as all these appear occasionally to hybridize, their limits must be regarded as very uncertain. Adopting the specific names usually given to the more familiar forms, the most important of the gourds, from an economic point of view, is perhaps *C. maxima*, the *Potiron* of the French, the red and yellow gourd of British gardeners, the splendorous fruit of which is remarkable for its enormous size and the colour of the somewhat rough and varies from white to bright yellow, while in some kinds it remains green, the fleshy interior is of a deep yellow or orange tint. This valuable gourd is grown extensively in southern Asia and Europe. In Turkey and Asia Minor it yields, at some periods of the year, an important article of diet to the people; immense quantities are sold in the markets of Constantinople, where in the winter the heaps of one variety with a white rind are described by Vahl as resembling mounds of snowballs. The yellow kind attains occasionally a weight of upwards of 210 lb. It grows well in central Europe and the United States, while in the south of England it will produce its gigantic fruit in perfection in hot summers. The yellow flesh of this gourd and its numerous varieties yields a considerable amount of nutriment, and is the most valuable as the fruit can be kept, even in warm climates, for a long time. In France and in the East it is much used in soups and ragouts, while simply boiled it forms a substitute for other table vegetables, the taste has been compared to that of a young carrot. In some countries the larger kinds are employed as cattle food. The seeds yield by expression a large quantity of a bland oil, which is used for the same purposes as that of the poppy and olive. The "mammoth" gourds of English and American gardeners appear to belong to this species, or to hybrids between it and another valuable member of the genus, the pumpkin, *C. Pepo*, well known in English cottage gardens, and largely cultivated in continental Europe and North America. The pumpkin varies much in form, being sometimes nearly globular, but more generally oblong or ovoid in shape, the rind is smooth, and very variable in colour. This gourd is a useful plant to the American backwoods farmer, yielding, both in the ripe and unripe condition, a valuable fodder for his cattle and pigs, being fre-

quently plucked at intervals among the vines, that takes his chief crop. The larger kinds acquire a weight from 40 to 80 lb, but smaller varieties are in much greater number for garden culture. When ripe, the pumpkin can be baked, or made into various kinds of pie, alone or with other fruit, while small and green it may be like the vegetable marrow. Some of the varieties *maxima* and *Pepo* contain a considerable quantity of seed amounting in the sweetest kinds to 1 or 2 percent of the hot plant, of Hungary cloths have been made of some of them as a connected source of nutriment. The shoots of both these large gourds may be given to the adult or being eaten as a green vegetable, when young. The vegetable marrow, *C. sativa*, is a small but delicate variety of *C. Pepo*, is much cultivated in England for its delicate flavour of its fruit, which is a small, round, immature state, as a pleasant summer vegetable. A number of varieties are in cultivation, the fruit of the pea shaped kinds growing a foot or more in length, some are comparatively small. The fruit of the *maxima* succeed in any warm and open situation, planted in small trench filled with manure, it often attains the fences of cottage gardens, and may be seen flourishing on the sunny side of walls. The south of England, *C. Maxima* is the most common gourd, favourite vegetable in the United States, the parts of continental Europe, but has not been introduced into the preceding. It is a somewhat variable member of the family, having more than 100 varieties, and towards a shabby mode of growth, the fruit, when ripe, is smaller than the pumpkin, the shape, usually with many upright ribs, and the fruit resembles a turnip, often many of the varieties of the *maxima* have been applied to the same purpose. The kinds is considerably smaller in the fruit, the squashes are much cultivated in the United States, grown as food for persons and cattle. The fruit is small, succulent, but cooking they have the same unripe condition. Many kinds are raised in India and other hot climates, and some are introduced into English gardens, rather for the foliage and leaves than for their value as vegetables. The *C. Acuminata*, the *acorn* gourd, is a small fruit, like a large orange in form and colour, and is generally too bitter to be fit for the table, but for culinary purposes in Turkey and the East, the *maxima*, *C. pepo*, *C. sativa*, and *C. acuminata* are generally eaten, especially in the immature state. Other gourds are used as a substitute for the *maxima* in some countries.

The bottle gourds are now produced in many countries, *Lagenaria*, the bottle gourd, is a small fruit, the authors being from instead of *maxima*. It is properly so called, *L. siliqua*, is a small fruit, downy, heart-shaped leaves and a small fruit, the remarkable fruit first begins to grow in the form of an elongated cylinder, but gradually widens to a round form, until, when ripe, it resembles a bottle, with a long neck and large rounded bulb. It sometimes attains a height of 7 feet. When ripe, the pulp is removed from the neck and the interior cleared by leaving water standing in the woody rind that remains is used as a bath. The lower part is cut off and cleared out, forming a vessel applied to the same domestic purposes as the bottle (*C. siliqua*) of the West Indies, the smaller variety divided lengthwise, forms a spoon, the ripe fruit is too bitter and astringent, but while immature it is used in the Arab and Turkish. When about the size of a cucumber," Lane says, it is stuffed with rice and meat, flavoured with pepper, onions, &c., and then

forming a favourite dish with Eastern peoples. The elongated snake gourds of India and China (*Pithecolanthus*) are said to be used in curries and stews.

All the gourds have a tendency to secrete the eschætic principle, *cobu guthan*, and in many varieties of *Cucurbita* and the allied genera it is often elaborated to such an extent as to render them unwholesome, or even poisonous. The seeds of some species possess rather strong anticholeric properties; those of the common pumpkin are frequently administered in America as a vomiting. The cultivation of gourds commenced far beyond the dawn of history, and the great art of spicing has become so modified by culture that the origin of plants from which they have descended can no longer be traced. The abundance of varieties in India would seem to indicate that part of Asia as the birth place of the present edible forms, but some appear to have been cultivated in all the hotter regions of that continent, and in North Africa, from the earliest ages, while the Romans were familiar with at least certain kinds of *Cucurbita*, and with the bottle gourd. It is even doubtful whether the culture of gourds had not spread to the American continent before its discovery by Europeans, for the inhabitants of the interior were certainly in possession of some kinds; it is date so early that it is difficult to believe they had preserved them from the settlers. Dr Aschitzky has even suggested that some of these eschætic forms may be already long and numerous to the American Indians.

Most of the annual gourd may be grown successfully in Britain. They are usually raised in hotbeds or under frames, and planted out in the early summer as soon as the middle of May. The more ornamental kinds may be trained over the wall, a favourite mode of displaying them in the East, but the situation must be sheltered and sunny. Even the *Lepanto* will sometimes produce fine fruit when sown in the southern counties. (C. P. T.)

CHARLES DE KEMP, Baron (1783-1852), a French general of artillery, was born at Versailles, 11th September 1783. After studying at the polytechnic school and at the artillery school of Châlons, he joined the artillery in 1802, and he purchased himself with distinction in several campaigns, he received in 1807 the cross of honour and the grade of captain. He served in the sub-sept Spanish and Italian campaigns, and in 1811 he was sent to report on the strength of the fortification of Danzig, a mission which he fulfilled so much to the satisfaction of Napoleon that he was named one of the emperor's ordinance officers. During the Russian campaign he was the first to enter the Kremlin at Moscow, where he removed the match from a large quantity of powder the explosion of which would in all probability have destroyed the emperor's life. For this service he received the title of baron. He accompanied the emperor in his subsequent campaigns, and in 1814, at the birth of Belgium, was again successful in delivering him from imminent peril. After the accession of Louis XVIII he was named chief of the staff of the first artillery division, but on the return of Napoleon from Elba he was nevertheless named by him adjutant and general, and took part in the battle of Waterloo. Being one of the three French officers chosen by Napoleon to accompany him to St Helena, he was employed there in collecting materials for a history of Napoleon's campaigns, but on account of some misunderstanding with Montholon, he left the island, and went to England. He published in 1818 *La Campagne de 1815*, and he also endeavoured to interest the emperors of Russia and Austria in Napoleon's behalf. Shortly afterwards he was expelled from England as a spy of Napoleon's. Returning to France in 1821, he published, along with Montholon, in 1823, *St. Pierre, Vainqueur & Grand-Vaincu*. His reply in 1825 to Ségur's *Histoire de la Grande Armée* was the occasion of a duel between the two authors; and he also,

in 1837, became involved in a controversy with Sir Walter Scott regarding some statements made by the latter in his life of Napoleon. After the July revolution of 1830, Gourgaud was appointed to the command of the artillery of Paris and Vincennes, in 1832 he was named aide de camp of the king, and in 1835 lieutenant general. In 1840 he was one of the commissioners sent to bring the remains of Napoleon to France. On the occurrence of the revolution of February 1848 his name was struck off the list of generals, but after the events of the following June he was chosen colonel of the first legion of the national guard of Paris. In 1849 he was elected representative of the legislative assembly for the department of Deux-Sèvres. He died 25th July 1852.

GOUT, a specific constitutional disorder connected with excess of urea and in the blood, and manifesting itself by inflammation of joints, with deposition therein of urate of soda, and also by morbid changes in various important organs.

The term *gout*, which was first used about the end of the 13th century, is derived through the French *goutte* from the Latin *gutta*, a drop, in allusion to the old physiological doctrine (which in the present case seems to be essentially the correct one) of the dropping of a morbid material from the blood within the joints. The disease is known and described by the ancient Greek physicians under various names, which, however, appear to have been applied by them alike to rheumatism and gout. The general term *arthritis* (*ἀρθριτις*, a joint) was employed when many joints were the seat of inflammation, while in those instances where the disease was limited to one part the terms used bore reference to such locality, hence *podagra* (*ποδᾶγρα*, from *πῶς*, the foot, and *ἀγρα*, a seizure), *cheirog* (*χερὶς*, the hand), *gonagra* (*γόνυ*, the knee), &c.

Hippocrates in his *Epidemics* speaks of gout as occurring most commonly in spring and autumn, and mentions the fact that women are less liable to it than men. He also gives directions as to treatment. Celsus gives a similar account of the disease. Galen regarded gout as an accumulation of humours in a part, and the chalkiness as the concretions of these, and he attributed the disease to over indulgence and luxury. Galen is alluded to in the works of Ovid and Pliny, and Seneca in his 95th epistle mentions the prevalence of gout among the Roman ladies of his day as one of the results of their high living and debauchery. Lucian in his *Tragopoeia* gives an amusing account of the remedies employed for the cure of gout.

In all times this disease has engaged a large share of the attention of physicians, from its wide prevalence, and from the amount of suffering which it entails. Sydenham, the famous English physician of the 17th century, wrote an important treatise on the subject, and his description of the gouty paroxysm, all the more vivid from his having himself been afflicted with the disease for thirty-four years, is still quoted by writers as the most graphic and exhaustive account of the symptomatology of gout. Subsequently Chillon, recognizing gout as capable of manifesting itself in various ways, divided the disease into *regular gout*, which affects the joints only, and *irregular gout*, where the gouty disposition exhibits itself in other forms, and the latter variety he subdivided into *acute gout*, where the most prominent symptoms are throughout referable to the stomach and alimentary canal, a *rhétoicent gout*, where the inflammatory attack suddenly disappears from an affected joint and serious disturbance takes place in some internal organ, generally the stomach or heart; and *muscular gout*, where from the first the disease does not appear externally, but reveals itself by an inflammatory attack of some internal part. Dr Garrod, one of the most eminent living authorities

on gout, adopts a division somewhat similar to that of Cullen, namely, *repeated gout*, which affects the joints alone, and is either acute or chronic, and *visceral gout*, affecting non-articular tissues, or disturbing the functions of various organs.

It is often stated that the attack of gout comes on with out any previous warning, but, while this is true in many instances, the reverse is probably as frequently the case, and the precursory symptoms, especially in those who have previously suffered from the disease, may be sufficiently precise to indicate the impending seizure. Among the more common of these may be mentioned marked disorders of the digestive organs, with a feeble and capricious appetite, flatulency and pain after eating, and vascularity in the right side in the region of the liver. A remarkable tendency to gnashing of the teeth is sometimes observed. This symptom was first noticed by Dr Graves, who connected it with irritation in the urinary organs, which also is present as one of the precursory indications of the gouty attack. Various forms of nervous disturbance also present themselves in the form of general discomfort, extreme irritability of temper, and various perverted sensations, such as that of numbness and coldness in the limbs. These symptoms may persist for many days, and then undergo amelioration immediately before the impending paroxysm. On the night of the attack the patient remains at rest apparently well, but about two or three o'clock in the morning is awake with a painful feeling in the foot, most commonly in the ball of the great toe, but it may be in the instep or heel, or in the thumb. With the pain there often occurs a distinct shivering followed by feverishness. The pain soon becomes of the most agonising character: in the words of Sydenham, "now it is a violent stretching and tearing of the ligaments, now it is a gnawing pain, and now a pressure and tightening, so exquisite and lively meanwhile is the part affected that it cannot bear the weight of the bedclothes, nor the jar of a person walking in the room."

When the affected part is examined it is found to be swollen and of a deep red hue. The superjacent skin is tense and glistening, and the surrounding veins are more or less distended. After a few hours there is a remission of the pain, slight perspiration takes place, and the patient may fall asleep. The pain may continue moderate during the day but returns as night advances, and the patient goes through a similar experience of suffering to that of the previous night, followed with a like abatement towards morning. These nocturnal exacerbations occur with greater or less severity during the continuance of the attack, which generally lasts for a week or ten days. As the symptoms decline the swelling and tenderness of the affected joint abate, but the skin over it pits on pressure for a time, and with this there is often associated slight desquamation of the cuticle. During the attacks there is much constitutional disturbance. The patient is restless and extremely irritable, and suffers from clasp in the limbs and from dyspepsia, thirst, and constipation. The urine is scanty and high coloured, with a copious deposit, consisting chiefly of urate. During the continuance of the symptoms the inflammation may leave the one foot and affect the other, or both may suffer at the same time. After the attack is over the patient feels quite well and fancies himself better than he had been for a long time before, hence the once popular notion that a fit of the gout was capable of removing all other ailments. Any such idea, however, is sadly belied in the experience of most sufferers from this disease. It is rare that the first is the only attack of gout, and another is apt to occur within a year, although by care and treatment it may be ward off. The disease, however, undoubtedly tends to take a firmer hold on the constitution and to return. In the earlier recurrences the same joints

as were formerly the seat of the gouty inflammation suffer again, but in course of time others become implicated, and in advanced cases scarcely any articulation escapes, and the disease thus becomes chronic. It is to be noticed that the gout assumes this form the frequently recurring attacks are usually attended with less pain than the earlier ones, but their disastrous effects are evidenced alike by the distention of various important organs, especially the stomach, liver, kidneys, and heart, and by the remarkable change which takes place in the joints from the formation of the so-called chalk stones or tophi. These deposits, which a highly characteristic of gout, appear at first to take place in the form of a semifluid material, consisting for the most part of urate of soda, which gradually becomes more dense and ultimately quite hard. When any quantity of this deposited in the structures of a joint the effect is to produce stiffening, and, as deposits appear to take place to a great or less amount in connexion with every attack, permanent thickening and deformity of the parts is apt to be the consequence. The extent of this depends of course on the amount of the deposits, which, however, would seem to be in no necessary relation to the severity of the attack, but in some cases even of chronic gout so slight as to be barely appreciable externally, but on the other hand occasional causing great enlargement of the joint, and fixing it in a flexed or extended position which renders it quite useless. Dr Garrod describes the appearance of a hand in an extreme case of this kind, and likens it to a bundle of French carrots with their heads forward, the hands corresponding to the stalks. Any of the joints may be affected, but most commonly those of the hand and foot. The deposits take place in other structures besides the joints, such as along the course of tendons, under the skin and periosteum, in the sclerotic coat of the eye, and especially on the cartilages of the external ear. When largely deposited in joints an abscess sometimes forms, the skin gives way, and the connection is exposed. Sir Thomas Watson quotes a case of this kind where the patient who playing at cards was accustomed to chalk the score of the game upon the table with his gouty knuckles.

The recognition of what is termed *incipient gout* is no easy than that form above described, where the disease gives abundant external evidence of its presence, but in other parts than joints suffer from gouty attacks is beyond question. The diagnosis may often be made in cases where in an attack of ordinary gout the disease suddenly leaves the affected joints and some new series of symptoms arise. It has been often observed when cold has been applied to an inflamed joint that the pain and inflammation in it had ceased, but that some sudden and alarming seizure is referable to the stomach, brain, heart, or lungs supervene. Such attacks, which correspond to what is termed by Cullen retro-cedent gout, often terminate favourably, more especially if the disease again returns to the joints. Further the gouty nature of some long continued internal or cutaneous disorders may be rendered apparent by its disappearance on the outbreak of the paroxysm in the joints. Gout, which is long standing, is often found associated with degenerative changes in the heart and large arteries, the liver, and especially the kidneys, which are apt to assume the contracted granular condition already alluded to as one of the forms of Bright's disease (see BRIGHT'S DISEASE). A variety of urinary calculi—the uric acid—formed by concretions of this substance in the kidneys is a not unfrequent occurrence in connexion with gout, hence the well known association of this disease and gravel.

As regards the pathology of gout, all inquiry agrees in connecting it closely with an altered state of the blood more particularly with the presence in that fluid in excess of amount of uric acid, and its subsequent deposition in the

joints in the form of uric acid. Uric acid is formed in the system in the processes of nutrition, and is excreted by the kidneys, the amount passing off by the urine being estimated at about 8 grains daily. In the healthy human subject the blood contains the mearest trace of this acid, but in gout it may be detected in abundance in the blood-serum both prior to and during the acute attack, while in chronic gout it becomes a constant constituent of the blood and of other fluids of the body, both natural and morbid. According to Dr Garrod it is not merely the presence of the uric acid in the blood, but its disposition in the inflamed part that gives rise to the attack of gout, the inflammation being the effect and not the cause of the deposit. The gouty paroxysm thus induced appears to rid the system to a certain extent of the accumulated uric acid, although such relief is generally of but temporary duration.

Whether the accumulation of urates in the blood be due, as some affirm, to their excessive formation in the system as the result of functional derangement of the liver, or, as others hold, depends simply on the defective excreting power of the kidneys of the duly amount, is disputed, although it has been often observed during an attack of gout that the amount of uric acid excreted was markedly deficient. This likelihood is that, both these conditions concur, and that while the kidneys retain their functional integrity, and even an excessive amount of uric acid in the system may be got rid of, but that these organs, becoming themselves affected by the deposition of urates in their tubular structure, lose to a large extent their excreting power, and thus the blood is overcharged with the product which the kidneys can no longer entirely remove. Another view of the pathology of gout recently advanced regards the disease as resulting from special degenerative changes in the fibrous textures of the body, one of the effects of which is the deposition of urates in the affected parts whence they pass into the blood. This theory has not, however, as yet been extensively supported, and the weight of opinion remains on the whole in favour of the views of Dr Garrod. It must nevertheless be admitted that many points in the pathology of this disease still remain unexplained, for, as remarked by Trousseau, "the production in excess of uric acid and urates is a pathological phenomenon inherent like all others in the disease, and like all the others it is dominated by a specific cause, which we know only by its effects, and which we term the gouty diathesis." This subject of diathesis (habit, or organic predisposition of individuals), which is universally admitted as an essential element in the pathology of gout, naturally suggests the question as to whether, besides being inherited, such a peculiarity may also be acquired, and thus leads to a consideration of the causes which are recognized as influential in favouring the occurrence of this disease.

It is beyond dispute that gout is in a marked degree hereditary, fully more than half the number of cases being, according to Sir C. Souhamore and Dr Garrod, of this character. But it is no less certain that there are habits and modes of life the observance of which may induce the disease even where no hereditary tendencies can be traced, and the avoidance of which may on the other hand go far towards weakening or neutralizing the influence of inherited liability. Gout is said to affect the sedentary more readily than the active, but this cannot be taken as a very constant rule. If, however, inadequate exercise be combined with a luxurious manner of living, with habitual over-indulgence in animal food and rich dishes, and especially in alcoholic beverages, then undoubtedly the chief factors in the production of the disease are present.

Much has been written upon the relative influence of various forms of alcoholic drinks in promoting the development of gout. It is generally stated that fermented are

more injurious than distilled liquors, and that, in particular, the stronger wines, such as port, sherry, and madeira, are much more potent in their gout-producing action than the lighter class of wines, such as hock, moselle, &c., while malt liquors are fully as hurtful as strong wines. If this alleged difference in their tendency to induce gout be correct, it cannot be said that any satisfactory explanation of it has been furnished, but indeed the point has not been clearly proved, and it may be fairly questioned whether, other things being equal, an individual in abandoning the use of wines and substituting that of spirits would improve his position in relation to this disease. It seems quite as probable that over-indulgence in any form of alcohol, when associated with the other conditions already adverted to, will have very much the same effect in developing gout. Even those who affirm the mischievous effects of fermented liquors in this way are obliged to admit that they are injurious in proportion to the amount of alcohol they contain. The comparative absence of gout in countries where spirituous liquors are chiefly used, such as Scotland, is cited as showing their relatively slight effect in encouraging that disease, but it is to be noticed that in such countries there is on the whole a less marked tendency to excess in the other pleasures of the table, which in no degree less than alcohol are chargeable with inducing the gouty habit. Gout is not a common disease among the poor and labouring classes, and when it does occur may often be connected even in them with excess in living. It is not very rare to meet gout in butlers, coachmen, &c., who are apt to live luxuriously while leading comparatively easy lives.

Gout, it must ever be borne in mind, may also affect persons who observe the strictest temperance in living, and whose only excesses are in the direction of over-work, either physical or intellectual. Many of the great names in history in all times have had their existence embittered by this malady, and have died from its effects. The influence of hereditary tendency may often be traced in such instances, and is doubtless called into activity by the depressing consequences of over-work. It may, notwithstanding, be affirmed as generally true that those who lead regular lives and are moderate in the use of animal food and alcoholic drinks, or still better abstain from the latter altogether, are little likely to be the victims of gout even when an undoubted inherited tendency exists.

Gout is more common in mature age than in the earlier years of life, the greatest number of cases in one decennial period being between the ages of thirty and forty, next between twenty and thirty, and thirdly between forty and fifty. It may occasionally affect very young persons, but such cases are generally in a marked degree hereditary. After middle life gout rarely appears for the first time. Women are much less the subjects of gout than men, apparently from their less exposure to the influences (excluding of course that of heredity) which tend to develop the disease, and doubtless also from the differing circumstances of their physical constitution. It most frequently appears in females after the cessation of the menses. Persons exposed to the influence of lead poisoning, such as plumbers, painters, &c., are apt to suffer from gout, and it would seem that impregnation of the system with this metal markedly interferes with the uric-acid-excreting function of the kidneys.

Attacks of gout are readily excited in those predisposed to the disease. Exposure to cold, disorders of digestion, fatigue, and irritation or injuries of particular joints will often precipitate the gouty paroxysm.

With respect to the treatment of gout the greatest variety of opinion has prevailed and practice been pursued, from the numerous *quant nostrum* detailed by Lincus to the "expectant" or do-nothing system recommended by Syden-

ham and gravely advocated by a few among eminent modern physicians, who regard the disease as beyond the reach of remedies. But that gout, although, as has been shown, a malady of a most severe and irremediable character, may nevertheless be successfully dealt with by appropriate medicinal and hygienic measures is a belief largely entertained, and one which happily guides the practice of the physician. The general plan of treatment can be here only briefly indicated. During the acute attack the affected part should be kept at perfect rest, and have applied to it warm opiate fomentations or poultices, or, what answers fully better, be enveloped in cotton wool covered in with oil silk. The diet of the patient should be light, without animal food or stimulants. The administration of some simple laxative will be of service, as well as the free use of alkaline effluvia, such as the bicarbonate or acetate of potash. The medicinal agent most to be relied on in the treatment of gout is colchicum, which manifestly exercises a powerful action on the disease. This drug (*Colchicum autumnale*), which is believed to correspond to the hermodactyl of the ancients, was introduced as a remedy for gout about a century ago, and has proved of such efficacy in modifying the attacks that, as observed by Dr Garrod, "we may safely assert that colchicum possesses as specific a control over the gouty inflammation as cinchona bark over their alkaloids over intermittent fever." The mode of action of colchicum in gout is by no means determined, since it would appear to have no certain effect upon the uric acid excreted from the system, and the general opinion seems to be that this drug has a special sedative effect on the gouty inflammation. It is usually administered in the form of the wine in doses of 10–30 drops every four or six hours, or in pill as the acetous extract (gr $\frac{1}{2}$ –gr 1). The effect of colchicum in subduing the pain of gout is generally so prompt and marked that it is unnecessary to have recourse to opiates, but its action requires to be carefully watched by the physician from its well known nauseating and depressing consequences, which, should they appear, render the suspension of the drug necessary. Otherwise the remedy may be continued in gradually diminishing doses for some days after the disappearance of the gouty inflammation. The statements often made that colchicum tends to encourage the speedy return of the disease do not seem to be well founded. Should gout give evidence of its presence in an irregular form by attacking internal organs, besides the medicinal treatment above mentioned, the use of frictions and mustard applications to the joints is indicated with the view of exciting its appearance there.

When gout has become chronic, colchicum, although of less service than in acute gout, is yet valuable, particularly when the inflammatory attacks recur. More benefit, however, appears to be derived from iodide of potassium, guaiacum, and more especially from the alkalis potash and lithia. This latter drug is strongly recommended by Dr Garrod from its solvent action upon the urates. It is usually administered in the form of the carbonate (gr v, freely diluted).

The treatment and regimen to be employed in the intervals of the gouty attacks are of the highest importance. These bear reference for the most part to the habits and mode of life of the patient. Restriction must be laid upon the amount and quality of the food, and equally, or still more, upon the alcoholic stimulants. "The instances," says Sir Thomas Watson, "are not few of men of good sense, and masters of themselves, who, being warned by one visitation of the gout, have thenceforward resolutely abstained from rich living and from wine and strong drinks of all kinds, and who have been rewarded for their prudence and self-denial by complete immunity from any return of the disease, or upon whom, at any rate, its future assaults have

been few and feeble." The same eminent authority adds—"I am sure it is worth any young man's while, who has had the gout, to become a teetotaler." By those more advanced in life who, from long continued habit, are unable entirely to relinquish the use of stimulants, the strictest possible temperance must be observed. Regular but moderate exercise in the form of walking or riding, in the case of those who lead sedentary lives, is of great advantage, and all over-work, either physical or mental, should be avoided. Unfortunately the complete carrying out of such directions, even by those who feel their importance, is too often rendered difficult or impossible by circumstances of occupation and otherwise, and at most only an approximation can be made. The effect upon the gouty constitution of certain mineral waters and baths is well known. The particular place most in each case be determined by the physician, and special caution must be observed in recommending this plan of treatment in persons whose gout is complicated by organic disease of any kind. (J O U)

GOUVION SAINT CYR, LAURENT, MARQUIS DE (1761–1830), a French marshal, was born at Toul, 13th April 1764. At the age of eighteen he went to Rome with the view of prosecuting the study of painting, but, although he continued his artistic studies after his return to Paris in 1784, he never definitely adopted the profession of a painter. In 1792 he was chosen a captain in the *chasseurs républicains*, and served on the staff of General Custine. His promotion rapidly followed, and in the course of two years he had become a general of division. In 1796 he commanded the centre division of Moreau's army in the campaign of the Rhine, and by coolness and sagacity greatly aided him in his brilliant defence against superior numbers, and in his subsequent celebrated retreat. In 1798 he was appointed to the command of the army of Italy, the officers of which had revolted against their general Anson, and he was speedily successful in obtaining the complete re-establishment of discipline. In the following year he commanded the left wing of Jourdan's army in Germany, but when Jourdan was succeeded by Massena, he joined the army of Moreau in Italy, where, in face of great difficulties, he was not only completely successful in his defensive tactics, but gained, on the 18th December, an important victory at Albano. When Moreau, in 1800, was appointed to the command of the army of the Rhine, Gouvion St Cyr was named his first lieutenant, and on the 9th May gained a victory over General Kray at Diersheim. In 1801 he was sent to Spain to command the army intended for the invasion of Portugal, and was named grand officer of the legion of honour. When a treaty of peace was shortly afterwards concluded with Portugal, he succeeded Lacerda e Barral as ambassador at Madrid. In 1803 he was appointed to the command of an army corps in Italy, and he gained in 1805 a victory over the Austrians at Castel Franco. He took part in the Prussian and Polish campaigns of 1807, and in 1808 he commanded an army corps with some success in Catalonia, but, not wishing to comply with certain orders he received from Paris, he resigned his command, and remained in disgrace till 1811. On the opening of the Russian campaign he received command of the 6th army corps, and on the 7th August 1812 obtained a victory over the Russians at Polotsk, in recognition of which he was created a marshal of France. He distinguished himself at the battle of Dresden, 26th and 27th August 1813, but, after a stubborn resistance, capitulated there to the allies on the 11th November following, and remained for some time a prisoner in Hungary. On the restoration of the Bonapartes he was created a peer of France, and in July 1815 was appointed war minister, but resigned his office in the November following. In June 1817 he was appointed minister of marine, and in September following again re-

sumed the duties of war minister, which he continued to discharge till November 1819. He died 17th March 1830. Gouverneur St Cyr was a prudent and cautious rather than a brilliant general, but he would doubtless have obtained better opportunities of acquiring distinction had he shown himself more blindly devoted to the interests of Napoleon.

He is the author of the following works—*Journal des opérations de l'armée de Catalogne, en 1808 et 1809*, Paris, 1821, *Mémoires sur les Campagnes des armées de Rhin et de Rhodé d'Alsace de 1791 à 1797*, Paris, 1828, and *Mémoires pour servir à l'histoire militaire sous le Directoire, le Consulat, et l'Empire*, 1831. See *Guy de Vichon's Vie du Gouverneur Saint Cyr*, 1867.

GOVERNMENT. Without attempting to discriminate by verbal definitions the various shades of meaning which this word assumes, we shall use it in this article in its widest sense—that of the ruling power in a political society. The conception of society which this use of the word implies may be illustrated by two well known theories.

In John Austin's celebrated analysis of law, the first step is the proposition that a law is a command issued by a superior to a subject and enforced by a sanction or penalty. The laws of God with reference to the conduct of men, the laws of a private club or association of men with reference to the conduct of its members, and the laws of a political society, are all, according to Austin's definition, laws properly so called. The laws of nature are laws not properly so called. They are generalizations as to the uniform course of nature, and have no analogy to laws properly so called except in point of uniformity. Positive law, again, is distinguished from other laws, properly so called, as the command of the sovereign of an independent political community. A sovereign is a person, or a determinate body of persons, to whom the bulk of the community is habitually obedient. Every word in this definition has its precise meaning, which is developed by Austin with admirable clearness. The faculty of "untying knots" on which he piled himself is nowhere more conspicuously manifested than in the analysis which lays bare the real meaning of the common phrases used to describe the fundamental parts of society. It is not our purpose to examine the value of this analysis here, but simply to call attention to the assumption that in every society of men there is a determinate body (whether consisting of one individual, or a few or many individuals) whose commands the rest of the community obey. This sovereign body is what in more popular phrase is termed the Government of the country, and the varieties which may exist in its constitution are known as forms of government.

Mr Herbert Spencer, approaching the study of society under the influence of conceptions derived from the study of physical organisms, brings us to very much the same result. The union of men in society is itself an organic structure, having parts and functions corresponding to the parts and functions of an animal or a plant. Mr Spencer pursues this analogy so fully and minutely as to leave the impression that he believes it to be something more than an analogy,—that it is a general law from which true deductions regarding society may be drawn. The veins and arteries correspond to our railroads and highways, the nerves, communicating intelligence to the brain, are paralleled by the telegraph wires, the centralized action of society at the seat of government is the same thing as the regulative activity of the brain. Governments here represented by the regulative functions of a living organism, and forms of government are so many varieties in the structure. Austin, for the purposes of jurisprudence, finds it convenient to regard society as moulded by the will of a dominant body. Spencer exhibits the regulative parts of society as bound up with the rest in one organism. With both the existence of a government is necessary to the conception of society. In the one theory the element of command, in the other that

of regulation, is conspicuous. If to these we add a third, that of simple agency, we shall have a tolerably complete view of the relations between Government and society. Besides commanding the conduct of individuals, besides regulating the relations of the various members of society, Government may be conceived of as merely the instrument of society. Where men are united in groups there arises from their union the necessity of action on behalf of the group. That part of society which attends to the business of the whole is the Government.

Two main lines of inquiry divide the subject. The first relates to varieties in the structure of the governing body—forms of government. The second relates to the functions of the governing body, the sphere of government, the things which fall within the province of state action. In both lines we have to deal with the ascertained facts of the past history and present condition of human societies. In both we have also to notice the speculative opinions of political thinkers. Notwithstanding the apparent confusion it will probably be found more convenient not to separate the historical from the speculative treatment of the subject. What is the best form of government?—is not quite the same question as What was the constitution of Athens or Rome? What are the proper limits of state interference?—is not the same question as What are the functions of the state in France or England? And yet the same answer may often serve for both sets of questions. Ideal constitutions have a suspicious resemblance to the constitutions with which then authors are most familiar. The political speculations of Plato and of Cicero are based on the state systems of Greece and Italy. Cicero's ideal code in his treatise *De Legibus* is simply an adaptation of the Twelve Tables. On the other hand, the form of political speculation is often determined by, and in turn determines, the practical politics of the time. The ultimate confusion between speculation and practice in politics is strikingly illustrated in the period of controversy which culminated in the Revolution of 1688. The irreconcilable claims of crown and parliament threw the mind back on first principles. Never had theorists a better chance. Popular government and absolute government each sought to establish itself on a basis of reason and nature. Filmer founds kindly authority on the natural subjection of mankind and the lineal succession of the king to Adam, the first and divinely appointed head of mankind. Locke's general theories of civil government were, in his own opinion, sufficient "to establish the throne of our great and present king, William, to make good his title in the consent of the people, which *being the only one of all lawful governments*, he has more fully and clearly than any prince in Christendom." We all know how the political issue was decided. The practical was not more complete than the speculative victory. For two centuries the speculations invented to support the popular cause against absolutism have been the accepted commonplaces of Englishmen on the constitution of civil society. A more recent example may be given from modern politics. During the discussions which preceded the passing of the Reform Act of 1867, no question was more hotly disputed than that of the real nature of the franchise. Was it a right or was it a privilege? In form this is a scientific or, if we like, a metaphysical question. But the answer to it depended on another question altogether—whether you wished the franchise to be extended to a larger class or not.

Origin of Government.—A preliminary question, formerly of vast theoretical importance, would be, What is the origin of government? How did government come into existence? As a question of historical fact, it demands for its solution a knowledge of the whole past of the human race. It has been answered over and over again in times when historical knowledge could hardly be said to exist,

and it has therefore been answered without any reference to history. The answers which have satisfied the minds of men may be distinguished broadly into three classes. The first class would comprehend the legendary accounts which nations have given in primitive times of their own founts of government. These are always attributed to the mind of a single lawgiver. The government of Sparta was the invention of Lycurgus. Solon, Moses, Numa, and Alfred in like manner shaped the government of their respective nations. There was no curiosity about the institutions of other nations,—about the origin of governments in general, and each nation was perfectly ready to accept the traditional *vœu* of any other.

The second may be called the logical or metaphysical account of the origin of government. It contained no overt reference to any particular form of government, whatever its covert references may have been. It answered the question, How government in general came into existence, and it answered it by a logical analysis of the elements of society. The phenomenon to be accounted for being government and laws, it abstracted government and laws, and contemplated mankind as existing without them. The characteristic feature of this kind of speculation is that it reflects how contemporary men would believe if all government were removed, and infers that men must have believed so before government came into existence. Society without government resolves itself into a number of individuals each following his own aims, and, therefore, in the days before government, each man followed his own aims. It is easy to see how this kind of reasoning should lead to very different views of the nature of the supposed original state. With Hobbes, it is a state of war, and government is the result of an agreement among men to keep the peace. With Locke, it is a state of liberty and equality,—it is not a state of war, it is governed by its own law,—the law of nature, which is the same thing as the law of reason. The state of nature is brought to an end by the voluntary agreement of individuals to surrender their natural liberty, and submit themselves to one supreme Government. In the words of Locke, "Men being by nature all free, equal, and independent, no one can be put out of this estate and subjected to the political power of another without his own consent. The only way whereby any one divests himself of his natural liberty, and puts on the *bounds of civil society*, is by agreeing with other men to join and unite into a community" (*On Civil Government*, c. viii). Locke boldly defends his theory as founded on historical fact, and it is amusing to compare his demonstration of the baseness of Filmer's speculations with the scanty and doubtful examples which he accepts as the foundation of his own. But in general the various forms of the hypothesis eliminate the question of time altogether. The original contract from which government springs is likewise the subsisting contract on which civil society continues to be based. The historical weakness of the theory was probably always recognized. Its logical inadequacy was conclusively demonstrated by Austin. But it still clings to speculations on the principles of government.

The "social compact" is the most famous of the metaphysical explanations of government. It has had the largest history, the widest influence, and the most complete development. To the same class belong the various forms of the theory that governments exist by divine appointment. Of all that has been written about the divine right of kings, a great deal must be set down to the mere fancies of courtiers and ecclesiastics. But there remains a genuine belief that men are bound to obey their rulers because their rulers have been appointed by God. Like the social compact, the theory of divine appointment avoided the question of historical fact.

The application of the historical method to the phenomena of society has changed the aspect of the question and robbed it of its political interest. The student of the history of society has no formula to express the law by which government is born. All that he can do is to trace governmental forms through various stages of social development. The more complex and the larger the society, the more distinct is the separation between the governing part and the rest, and the more elaborate is the subdivision of functions in the government. The primitive type of ruler is king, judge, priest, and general. At the same time his way of life differs little from that of his followers and subjects. The metaphysical theories were so far right in imputing greater equality of social conditions to more primitive times. Increase of bulk brings with it a more complex social organization. War tends to develop the strength of the governmental organization, peace relaxes it. All societies of men exhibit the germs of government, but these would appear to be races of men so low that they cannot be said to live together in society at all. Recent investigations have illustrated very fully the importance of the family in primitive societies, and the belief in a common descent has much to do with the social cohesion of a tribe. The government of a tribe resembles the government of a household, the head of the family is the ruler. But we cannot admit that political government has its origin in family government, or that there may not have been states of society in which government of some sort existed while the family did not.

I. FORMS OF GOVERNMENT

Three Standard Forms.—Political writers from the time of Aristotle have been singularly unanimous in their classification of the forms of government. There are three ways in which states may be governed. They may be governed by one man, or by a number of men, small in proportion to the whole number of men in the state, or by a number large in proportion to the whole number of men in the state. The government may be a monarchy, an aristocracy, or a democracy. The same terms are used by Austin as were used by Aristotle, and in very nearly the same sense. The determining quality in governments in both writers, and it may safely be said in all intermediate writers, is the numerical relation between the constituent members of the government and the population of the state. There were, of course, enormous differences between the state systems present to the mind of the Greek philosopher and the English jurist. Aristotle was thinking of the small independent states of Greece, Austin of the great peoples of modern Europe. The unit of government in the one case was a city, in the other a nation. This difference is of itself enough to invalidate all generalization founded on the common terminology. But on one point there is a complete parallel between the politics of Aristotle and the politics of Austin. The Greek cities were to the rest of the world very much what European nations and European colonies are to the rest of the world now. They were the only communities in which the governed visibly took some share in the work of government. Outside the Patroan system, as outside the Greek system, we have only the stereotyped uniformity of despotism, whether savage or civilized. The question of forms of government, therefore, belongs entirely to the European races. The virtues and defects of monarchy, aristocracy, and democracy are the virtues and defects manifested by the historical governments of Europe. The generality of the language used by political writers must not blind us to the fact that they are thinking only of a comparatively small portion of mankind.

Greek Politics.—Aristotle divides governments according to two principles. In all states the governing power seeks

either its own advantage or the advantage of the whole state, and the government is bad or good accordingly. In all states the governing power is one man, or a few men, or many men. Hence six varieties of government, three of which are bad and three good. Each excellent form has a corresponding depraved form. Thus —

The good government of one (Monarchy) corresponds to the depraved form (Tyranny)

The good government of few (Aristocracy) corresponds to the depraved form (Oligarchy)

The good government of many (Commonwealth) corresponds to the depraved form (Democracy)

The fault of the depraved forms is that the governors act unjustly where their own interests are concerned. The worst of the depraved forms is tyranny, the next oligarchy, and the least bad democracy.¹ Each of the three leading types exhibits a number of varieties. Thus in monarchy we have the heroic, the barbaric, the elective dictatorship, the Lacedæmonian (hereditary) kingship, *σπερσπύδα*, and absolute monarchy. So democracy and oligarchy exhibit four corresponding varieties. The best type of democracy is that of a community mainly agricultural, whose citizens, therefore, have not leisure for political affairs, and allow the law to rule. The best oligarchy is that in which a considerable number of small proprietors have the power, i.e., too, the laws prevail. The worst democracy consists of a large citizen class having leisure for politics, and the worst oligarchy is that of a small number of very rich and influential men. In both the sphere of law is reduced to a minimum. A good government is one in which as much as possible is left to the laws, and as little as possible to the will of the governor.

The *Politeia* of Aristotle, from which these principles are taken, presents a striking picture of the variety and activity of political life in the free communities of Greece. The king and council of heroic times had disappeared, and self-government in some form or other was the general rule. It is to be noticed, however, that the Governments of Greece were essentially unstable. The political philosophers could lay down the law of development by which one form of government gives birth to another. Aristotle devotes a large portion of his work to the consideration of the causes of revolutions. The dread of tyranny was kept alive by the facility with which an over-powerful and unscrupulous citizen could seize the whole machinery of government. Communities oscillated between some form of oligarchy and some form of democracy. The security of each was constantly imperilled by the conspiracies of the opposing factions. Hence, although political life exhibits that exuberant variety of form and expression which characterizes all the intellectual products of Greece, it lacks the quality of persistent progress. Then there was no approximation to a national government, even of the federal type. The varying confederacies and hegemonies are the nearest approach to anything of the kind. What kind of national government would ultimately have arisen if Greece had not been crushed it is needless to conjecture, the true interest of Greek politics lies in the fact that the free citizens were, in the strictest sense of the word, self-governed. Each citizen took his turn at the common business of the state. He spoke his own views in the agora, and from time to time in his own person acted as magistrate or judge. Citizenship in Athens was a liberal education, such as it never can be made under any representative system.

The Government of Rome.—During the whole period of freedom the government of Rome was, in theory at least, municipal self-government. Each citizen had

a right to vote laws in his own person in the *comitia* of the centuries or the tribes. The administrative powers of government were, however, in the hands of a bureaucratic assembly, recruited from the holders of high public office. The senate represented capacity and experience rather than rank and wealth. Without some such instrument the city government of Rome could never have made the conquest of the world. The gradual extension of the citizenship to other Italians changed the character of Roman government. The distant citizens could not come to the voting booths, the device of representation was not discovered, and the *comitia* fell into the power of the town voters. In the last stage of the Roman republic, the inhabitants of one town wielded the resources of a world-wide empire. We can imagine what would be the effect of leaving to the people of London or Paris the supreme control of the British empire or of France,—a terrible temptation, inevitable corruption. The rabble of the capital learn to live on the rest of the empire.² The favour of the effeminate masters of the world is purchased by *panem et circenses*. That capable officers and victorious armies should long be content to serve such masters was impossible. A conspiracy of generals placed itself at the head of affairs, and the most capable of them made himself sole master. Under Cæsar, Augustus, and Tiberius, the Roman people became habituated to a new form of government, which is best described by the name of Cæsarism. The outward forms of republican government remained, but one man united in his own person all the leading offices, and used them to give a seemingly legal title to what was essentially military despotism. There is no more interesting constitutional study than the chapters in which Tacitus traces the growth of the new system under the subtle and dissimulating intellect of Tiberius. The new Roman empire was as full of fictions as the English constitution of the present day. The master of the world posed as the humble servant of a menial senate. Despotic the outward symbols of sovereignty, he was adorned with the modest powers of a consul or a tribune plebeius. The reign of Tiberius, little capable as he was by personal character of captivating the favour of the multitude, did more for imperialism than was done by his most famous predecessors. Henceforward free government all over the world lay crushed beneath the military despotism of Rome. Cæsarism remained true to the character imposed upon it by its origin. The Cæsar was an elective not an hereditary king. The real foundation of his power was the army, and the army in course of time perpetually assumed the right of nominating the sovereign. The characteristic weakness of the Roman empire was the uncertainty of the succession. The nomination of a Cæsar in the lifetime of the emperor was an ineffective remedy. Rival emperors were elected by different armies, and nothing less than the force of arms could decide the question between them.

Modern Governments—Feudalism.—The Roman empire bequeathed to modern Europe the theory of universal dominion. The nationalities which grew up after its fall arranged themselves on the basis of territorial sovereignty. Leaving out of account the free municipalities of the Middle Ages, the problem of government had now to be solved, not for small urban communities, but for large territorial nations. The medieval form of government was feudal. One common type pervaded all the relations of life. The relation of king and lord

¹ None of the free states of Greece ever made extensive or permanent conquests, but the tribute sometimes paid by one state to another (as by the *Arginates* to the Athenians) was a manifest source of corruption. Compare the remark of Hume (*History*, part i. 3, *That Politics may be reduced to a Science*), "free governments are the most ruinous and oppressive to their provinces."

² Aristotle elsewhere speaks of the error of those who think that any one of the depraved forms is better than any other.

was like the relation between lord and vassal (see *Fraser's* *History*). The bond between them was the tenure of land. In England there had been, before the Norman Conquest, an approximation to a feudal system. In the earlier English constitution, the most striking features were the power of the witan, and the common property of the nation in a large portion of the soil. The steady development of the power of the king kept pace with the aggregation of the English tribes under one king. The conception that the land belonged primarily to the people gave way to the conception that everything belonged primarily to the king.¹ The Norman Conquest imposed on England the already highly developed feudalism of France, and out of this feudalism the free governments of modern Europe have grown. One or two of the leading steps in this process may be indicated here. The first, and perhaps the most important, was the device of representation. For an account of its origin, and for instances of its use in England before its application to politics, we must be content to refer to Canon Stubbs's *Constitutional History*, vol. II. The problem of combining a large area of sovereignty with some degree of self government, which had proved fatal to ancient commonwealths, was henceforward solved. From that time some form of representation has been deemed essential to every constitution professing, however remotely, to be free.

The connection between representation and the feudal system of estates must be shortly noticed. The feudal theory gave the king a limited right to military service and to certain aids, both of which were utterly inadequate to meet the expenses of the government, especially in time of war. The king therefore had to get contributions from his people, and he consulted them in their respective orders. The three estates were simply the three natural divisions of the people, and Canon Stubbs has pointed out that, in the occasional treaties between a noblesse and king and the order of merchants or lawyers, we have examples of inchoate estates or sub estates of the realm. The right of representation was thus in its origin a right to consent to taxation. The pure theory of feudalism had from the beginning been broken by William the Conqueror causing all freeholders to take an oath of direct allegiance to himself. The institution of parliaments, and the association of the king's smaller tenants *in capite* with other commoners, still further removed the government from the purely feudal type, in which the mere lord stands between the inferior vassal and the king.

Parliamentary Government.—The English System.—The right of the commons to share the power of the king and hold a share in legislation, the exclusive right of the commons to impose taxes, the disappearance of the clergy as a separate order, were all important steps in the movement towards popular government. The extinction of the old feudal nobility in the dynastic wars of the 15th century simplified the question by leaving the crown face to face with parliament. The immediate result was no doubt an increase in the power of the crown, which probably never stood higher than it did in the reigns of Henry VIII and Elizabeth, but even those powerful monarchs were studious in their regard for parliamentary conventionalities. After a long period of speculative controversy and civil war, the settlement of 1688 established limited monarchy as the government of England. Since that time the external form of government has remained unchanged, and so far as legal

¹ Ultimately, in the theory of English law, the king may be said to have become the universal successor of the people. Some of the peculiarities of the prerogative rights seem to be explicable only on this view, e.g., the curious distinction between wrecks come to land and wrecks still on water. The common right to wrecks was no doubt the origin of the prerogative right to the former. Every monarch must right has come to be a right of the crown or a right held of the crown by a vassal.

description goes, the constitution of William III might be taken for the same system as that which still exists. The silent changes have, however, been enormous. The most striking of these, and that which has produced the most salient features of the English system, is the growth of cabinet government. Intimately connected with this is the rise of the two great historical parties of English politics. The normal state of government in England is that the cabinet of the day shall represent that which is, for the time, the stronger of the two. Before the Revolution the king's ministers had begun to act as a united body, but even after the Revolution the union was still feeble and fluctuating, and each individual minister was bound to the others only by the tie of common service to the king. Under the Hanoverian sovereigns the ministry became consolidated, the position of the cabinet became definite, and its dependence on parliament, and more particularly on the House of Commons, was established. Ministers were chosen exclusively from one house or the other, and they assumed complete responsibility for every act done in the name of the crown. The simplicity of English politics has divided parliament into two nearly equal parties, and the party in opposition has been steadied by the consciousness that it, too, has constitutional functions of high importance. Citizenship is sobred by being made responsible. Along with this movement went the withdrawal of the personal action of the monarch in politics. No king has attempted to veto a bill since the Scotch Militia Bill was vetoed by Queen Anne. No ministry has been dismissed by the sovereign since 1834. Whatever the power of the monarch may be, it is unquestionably limited to his personal influence over his ministers. And it must be remembered that ministers are responsible ultimately, not to parliament, but to the House of Commons.

Apart, therefore, from the democratic changes of 1832 and 1867, we find that the House of Commons, as a body, had gradually made itself the centre of the government. Since the area of the constitution has been enlarged, it may be doubted whether the order of description of the government any longer apply. The earlier constitutional writers, such as Blackstone and Dolmeac, regard it as a wonderful compound of the three standard forms,—monarchy, aristocracy, and democracy. Each has its place, and each acts as a check upon the others. Hence, discussing the question "Whether the British government inclines more to absolute monarchy or to a republic," decides in favour of the former alternative. "The tide has run long and with some rapidity to the side of popular government, and is just beginning to turn toward monarchy." And he gives it as his own opinion that absolute monarchy would be the easiest death, the true enthusiasm of the English constitution. These views of the English Government in the 18th century may be contrasted with Mr. Bagehot's sketch of the modern government as a working instrument.²

Leading Features of Parliamentary Government.—The parliamentary government developed by England out of feudal materials has been deliberately accepted as the type of constitutional government all over the world. Nearly all the European states and nearly all the European colonies, dependent or independent, have adopted it, more or less fully, the leading features of the English system—that is to say, popular representation more or less extensive, a bicameral legislature, and a cabinet or consolidated ministry. In connexion with all of these, numberless questions of the highest practical importance have arisen, the exact enumeration of which would surpass the limits of our space. We shall confine ourselves to a few very general considerations.

² See Bagehot's *English Constitution*.

The Two Chambers.—First, as to the double chamber. This, which is perhaps more accidental than any other portion of the English system, has been the most widely imitated. In most European countries, in the English colonies, in the United States congress, and in the separate States of the Union,¹ there are two houses of legislation. This result has been brought about partly by natural imitation of the accepted type of free government, partly from a conviction that the second chamber will moderate the democratic tendencies of the first. The theoretical question would take too long to argue, but it is easy to show that the elements of the English original cannot be reproduced to order under different conditions.² These have, indeed, been a few attempts to imitate the special character of hereditary nobility attaching to the English House of Lords, and these few have failed. The complete solidarity existing between the English nobility and at least the politically privileged, if not the whole mass, of their countrymen, is a result not to be attempted by the framers of constitutions. The English system, too, after its own way, obviates any danger of collision between the Houses,—the standing and obvious danger of the bicameral system. In England there is no doubt where the real sovereignty lies. The actual ministers of the day must possess the confidence of the House of Commons, they need not—in fact they often do not—possess the confidence of the House of Lords. It is only in legislation that the Lower House really shares its powers with the Upper, and the constitution possesses, in the unlimited power of nominating peers, a well understood last resource should the House of Lords persist in refusing important measures demanded by the representatives of the people. In all but measures of first class importance, however, the House of Lords is a real second chamber, and in these there is little danger of a collision between the Houses. There is the widest possible difference between the English and any other second chamber. In the United States the senate (constituted on the system of equal representation of States) is the more important of the two Houses, and the only one whose control of the executive can be compared to that exercised by the British House of Commons. In the English colonies a dead-lock between the two Houses is a matter of frequent occurrence. In France, it is as anticipated if not an intended source of danger to the new republican constitution.

The real strength of popular government in England lies in the ultimate supremacy of the House of Commons. That supremacy had been acquired, perhaps to its full extent, before the extension of the suffrage made the constituencies democratic. Foreign imitators, it may be observed, have been more ready to accept a wide basis of representation than to confer real power on the representative body. In all the monarchical countries of Europe, however unrestricted the right of suffrage may be, the real victory of constitutional government has yet to be won. Where the suffrage means little or nothing, there is little or no reason for guarding it against abuse. The independence of the executive in the United States brings that country, from one point of view, more near to the Continental than to the English state system. The people make a more complete surrender of power to the Government than is done in England.

Cabinet Government.—The peculiar functions of the English cabinet are not easily matched in any foreign system. They are a mystery even to most educated

Englishmen. The cabinet in England is much more than a body consisting of chiefs of departments. It is the inner council of the empire, the arbiter of national policy, foreign or domestic, the sovereign in commission. The whole power of the House of Commons is concentrated in its hands. At the same time, it has no place whatever in the legal constitution. Its numbers and its constitution are not fixed even by any rule of practice. It keeps no record of its proceedings. The relations of an individual minister to the cabinet, and of the cabinet to its head and creator, the premier, are things known only to the initiated.³ With the doubtful exception of France, no other system of government presents us with anything like its equivalent. In the United States, as in the European monarchies, we have a council of ministers surrounding the chief of the state.

Change of Power in the English System.—One of the most difficult problems of government is how to provide for the devolution of political power, and perhaps no other question is so generally and justly applied as the test of a working constitution. If the transmission works smoothly, the constitution, whatever may be its other defects, may at least be pronounced stable. It would be tedious to enumerate all the contrivances which this problem has suggested to political societies. Here, as usual, Oriental despotism stands at the bottom of the scale. When sovereign power is imputed to one family, and the law of succession fails to designate exclusively the individual entitled to succeed, assassination becomes almost a necessary means of ascension. The prince whom chance or intrigue has promoted to the throne of a father or an uncle, must make himself safe from his relatives and competitors. Hence the scenes which shock the European conscience when "Amurath an Amurath succeeds." Constantinople, Afghanistan, and Burmah have all recently illustrated the standing difficulty of the succession in Oriental despotisms. The strong monarchical governments of Europe have been saved from this evil by an indisputable law of succession, which marks out from his infancy the next successor to the throne. The king names his ministers, and the law names the king. In popular or constitutional governments far more elaborate precautions are required. It is one of the real merits of the English constitution that it has solved this problem—in a roundabout way perhaps, after its fashion—but with perfect success. The ostensible seat of power is the throne, and down to a time not long distant the demise of the crown suspended all the other powers of the state. In point of fact, however, the real change of power occurs on a change of ministry. The constitutional practice of this century has settled, beyond the reach of controversy, the occasions on which a ministry is bound to retire. It must resign or dissolve when it is defeated in the House of Commons, and if after a dissolution it is beaten again, it must resign without alternative. It may resign if it thinks its majority in the House of Commons not sufficiently large. The dormant functions of the crown now come into existence. It receives back political power from the old ministry in order to transmit it to the new. When the new ministry is to be formed, and how it is to be formed, is also clearly settled by established practice. The outgoing premier names his successor by recommending the king to consult him, and that successor must be the recognized leader of his successful rivals. All this is a matter of custom, not of law, and it is doubtful if any two authorities could agree in describing the custom in

¹ The double government in the last case was founded, says Sir G. Lewis, on the English municipal system, and corresponded to the difference between aldermen and common council men.

² Sweden, a few years since, reduced her from medieval estates to two houses, and is more like Great Britain in the composition of the new parliament than any other state in Europe.

³ See Bagehot's *English Constitution*, which exhibits a working view of this and other parts of the constitution as they appear to an outsider. Mr Gladstone's political essays, in the collection entitled *Elements of Past Years*, contain much valuable information at first hand.

language of precision. It is certain that the intervention of the crown facilitates the transfer of power from one party to another, by giving it the appearance of a mere change of servants. The real disturbance is that caused by the appeal to the electors. A general election is always a struggle between the two great political parties for the possession of the powers of government. It may be noted that recent practice goes far to establish the rule that a ministry beaten at the hustings should resign at once without waiting for a formal defeat in the House of Commons.

The English custom makes the ministry dependent on the will of the House of Commons, and, on the other hand, the House of Commons itself is dependent on the will of the ministry. In the last result both depend on the will of the constituencies as expressed at the general election. There is no fixity in either direction in the tenure of a ministry. It may be challenged at any moment, and it lasts until it is challenged and beaten. And that there should be a ministry and a House of Commons in harmony with each other but out of harmony with the people is rendered all but impossible by the law and the practice as to the duration of parliaments.

Change of Power in the United States—The United States offers a very different solution of the problem. The American president is at once king and prime minister, and there is no titular person to act as a conduit-type between him and his successor. His crown is rigidly fixed, unshakable for four years, after four years he ceases to reign. No hostile vote can affect his power as the head of the administration, and it is difficult to resist him, will even in legislation. But the day of his demise is known from the first day of his government, and almost before he begins to reign the political forces of the country are shaping out a new struggle for the succession. Further, a change of government in America means a change of the entire administrative staff. The commotion caused by a presidential election in the United States is thus infinitely greater than that caused by a general election in England. A change of power in England affects comparatively few personal interests, and absorbs the attention of the country for a comparatively short space of time. In the United States it is long foreseen and elaborately prepared for, and when it comes it involves the personal fortunes of large numbers of citizens. And yet the English constitution is more democratic than the American, in the sense that the popular will can move speedily be brought to bear upon the government.

Change of Power in France—The established practice of England and America may be compared with the nascent constitution of France. Here the problem presents different conditions. The head of the state is neither a premier of the English, nor a president of the American type. He is served by a prime minister and a cabinet, who, like an English ministry, hold office on the condition of parliamentary confidence, but he holds office himself on the same terms, and is, in fact, a minister like the others. So far as the transmission of power from cabinet to cabinet is concerned, he discharges the functions of an English king. But the transmission of power between himself and his successor is protected by no constitutional device whatever, and recent experience would seem to show that no such device is really necessary. Of course it is too soon to talk about the constitutional practice in France, but this much seems clear, that some rearrangement of the relations of the president and the cabinet must soon take place. It seems difficult to distinguish between a parliamentary president and a parliamentary ministry, or to see why they should not stand or fall together. As yet the new French constitution has not had time to exhibit that which is a constant feature of the English constitution, viz.,

a government headed by the chief of the dominant political party. When that time comes the office of premier ought, one would suppose, to merge in the office of president. Possibly the existence of numerous political parties, and the open disloyalty to the existing constitution professed by some of them, may retard the simplification of the French governmental system. Other European countries professing constitutional government appear to follow the English practice. The Swiss republic is so peculiarly situated that it is hardly fair to compare it with any other. But it is interesting to note that, while the rulers of the states are elected annually, the same persons are generally re-elected.

Representation—The questions connected with representation are too numerous to be discussed with advantage here. Two recent changes of great importance may be noticed in the English system,—the vote by ballot, and the partial introduction of what is called the minority vote. By the latter, in a constituency returning three members, each elector has only two votes, and a minority exceeding one-third can thus elect at least one of the three. The representation of minorities is a device of political theorists, and the chief result of its partial application has been to weaken the influence of the large constituencies. The chief anomalies of the English system are the inequality of electoral districts and the multiplicity of votes. A town of 800 electors returns as many candidates as a constituency of ten times that number. On the other hand, while one man has a single vote only, his neighbour, by various qualifications, can be an elector in several constituencies. In each case there is a revolution of the only theory on which the representative system as a whole can be founded—the equality of the voters. The first of these anomalies is admittedly waiting the convenience of political parties. The second has been recently aggravated by the creation of new university constituencies, consisting almost entirely of persons who had already the right of voting under the ordinary qualification. The anomaly becomes a gross abuse in the practice of creating what are known as *gaggle* votes. The simple remedy would be to require that each elector should be registered in one constituency only.

The Relation between Government and Law—It might be supposed that, if any general proposition could be established about government, it would be one establishing some constant relation between the form of a government and the character of the laws which it enforces. The technical language of the English school of jurists is certainly of a kind to encourage such a supposition. The entire body of law in force in a country at any moment is regarded as existing solely by the fiat of the governing power. There is no maximum term entirely in the spirit of this jurisprudence than the following—"The real legislator is not he by whom the law was first ordained, but he by whose will it continues to be law." The whole of the vast repository of rules which make up the law of England—the rules of practice in the courts, the local customs of a county or a manor, the principles formulated by the sagacity of generations of judges, equally with the statutes for the time, are conceived of by the school of Austin as created by the will of the sovereign and the two Houses of Parliament, or so much of them as would now satisfy the definition of "sovereignty." It would be out of place to examine here the difficulties which embrace this definition, but the statement we have made carries on its face a demonstration of its own falsity in fact. There is probably no government in the world of which it could be said that it might change at will the substantive laws of the country and still remain a government. However well it may suit the purposes of analytical jurisprudence to define a law as a command set by sovereign to subject, we must not forget that this is only a definition, and that the assumption it rests upon is,

to the student of society, anything but a universal fact. From his point of view the cause of a particular law is not one but many, and of the many the deliberate will of a legislator may not be one. Sir Henry Maine has illustrated this point by the case of the great tax-gathering empires of the East, in which the absolute master of millions of men never dreams of making anything in the nature of a law at all. This view is no doubt as strange to the English statesman as to the English jurist. The most conspicuous work of government in his view is that of parliamentary legislation. For a large portion of the year the attention of the whole people is bent on the operations of a body of men who are constantly engaged in making new laws. It is natural for us, therefore, to think of law as a factitious thing, made and unmade by the people who happen for the time being to constitute parliament. We forget how small a proportion the laws actually devised by parliament are of the law actually prevailing in the land. No European country has undergone so many changes in the form of government as France. Republic, constitutional monarchy, and empire have there succeeded each other again and again in the course of a century. It is surprising how little effect these political revolutions have had on the body of French law. The change from empire to republic is not marked by greater legislative activity than the change from a Conservative to a Liberal ministry in England would be.

These reflections should make us cautious in accepting any general proposition about forms of government and the spirit of their laws. We must remember, also, that the classification of governments according to the numerical proportion between governors and governed supplies but a small basis for generalization. What parallel can be drawn between a small town, in which half the population are slaves, and every freeman has a direct voice in the government, and a great modern state, in which there is not a single slave, while freemen exercise their sovereign powers at long intervals, and through the action of delegates and representatives? Propositions as vague as those of Montesquieu may indeed be assented to with more or less plausibility. But to take any leading head of positive law, and to say that monarchies treat it in one way, aristocracies and democracies in another, is a different matter. Laws affecting trade might be expected to depend on the more or less popular character of the government. Yet would it be safe to say that monarchy discourages, that democracy encourages, free trade? France under the empire was more free-trading than France under the republic. If there is any difference at all between Great Britain and her colonies it is that the latter are generally supposed to be more democratic than the mother country. Yet protection rules the young democracies, while free trade reigns at home. The principle has indeed been broadly laid down that oligarchical governments interfere more actively and more extensively in the affairs of their subjects than popular governments. We shall have occasion to show directly that the popularization of government in England has up to this time been attended by a striking increase in the sphere of state action.

II. SPHERE OF GOVERNMENT

We may now ask, What is the appropriate sphere of government? What kind of business does it undertake, and what kind of business ought it to undertake? By what limits is its action to be restricted? Here too the field is occupied by disputed theories and diversified practices. And the sphere assigned to state action in different ages and countries varies as widely as the form of government.

The action of the state, or sovereign power, or government in a civilized community shapes itself into the threefold functions of legislation, judicature, and administration. The two first are perfectly well defined, and the last includes

all the kinds of state action not included in the other two. It is with reference to legislation and administration that the line of permissible state action requires to be drawn. There is no doubt about the province of the judicature, and that function of government may therefore be dismissed with a very few observations.

The complete separation of the three functions marks a high point of social organization. In simple societies the same officers discharge all the duties which we divide between the legislator, the administrator, and the judge. The acts themselves are not consciously recognized as being of different kinds. The evolution of all the parts of a highly complex government from one original is illustrated in a striking way by the history of English institutions. All the conspicuous parts of the modern government, however little they may resemble each other now, can be followed back without a break to their common origin. Parliament, the cabinet, the privy council, the courts of law, all carry us back to the same *modus* in the council of the feudal king.

Judicature.—The business of judicature, requiring as it does the possession of a high degree of technical skill and knowledge, is generally entrusted by the sovereign body or people to a separate and independent class of functionaries. In England, the appellate jurisdiction of the House of Lords still maintains a theory the connexion between the supreme legislative and the supreme judicial functions. It is only recently that the important subject of divorce passed from the legislative chambers to the courts of law. In some of the States of the American Union the judicial functions of the upper house are still maintained after the example of the English constitution as it existed when those States were founded. In England there is also still a considerable amount of judicial work in which the people takes its share. The inferior magistracies, except in populous places, are in the hands of private persons. And by the jury system the ascertainment of fact has been committed in very large measure to persons selected indiscriminately from the mass of the people, subject to a small property qualification. But the higher functions of the judicature are excluded by persons whom the law has jealously fenced off from external interference and control. The independence of the bench distinguishes the English system from every other. It was established in principle as a barrier against monarchical power, and hence has become one of the traditional ensigns of popular government. In many of the American States, the spirit of democracy has demanded the subjection of the judiciary to popular control. The judges are elected directly by the people, and hold office for a short term, instead of being appointed, as in England, by the responsible executive, and removable only by a vote of the two Houses. There is not the smallest sign that democratic opinion in England is tending in this direction. At the same time the constitution of the United States has assigned to the supreme court of the Union a perfectly unique position, standing in singular contrast to the degraded condition of many of the State judiciaries. The supreme court is the guardian of the constitution. It has to judge whether a measure passed by the legislative powers is not void by reason of being unconstitutional, and it may therefore have to veto the deliberate resolutions of both Houses of Congress and the president. It is admitted that this singular experiment in government has been completely justified by its success.

¹ It is worth noting that direct election to offices—supposed to be disadvantageous to the democratic spirit—has no place in English political life. The few instances in which it occurs are regarded with suspicion. The election of the coroner by the freeholders is universally condemned. In the few parishes where the clergyman may be appointed by the parishioners, the right is often left to be exercised by the bishop.

action must be regulated by conscience, and that its religious obligations are the same as those of the individual man. It must therefore recognize and practise a religion, and the true religion is that of the Christian Church, of which the English Establishment is a branch. That religion, with its divinely organized system of Episcopacy, the state should enforce in every way short of physical persecution. It should exclude heretics from office and privilege, but it should not put them in prison. Mr Gladstone's book was the occasion of a controversy which doubtless had some effect on subsequent political events. Macaulay² stated the Whig view of the subject—holding that while the state may justifiably endow an established church, it may not persecute for dissent in any way whatever. Government has principally to deal with the material wants of society, and with the protection of life and property. While this is the main end of government, it may pursue such secondary ends as the promotion of education and religion, the encouragement of arts, &c., but the primary end must not be sacrificed to the secondary end. The state is therefore not a moral power at all, any more than a railway company or a hospital, and government is certainly not an institution for the promotion of religion, but, if it finds it expedient, it may justly support Presbyterianism in Scotland, Protestant Episcopacy in England, and Roman Catholicism in Ireland. It is needless to say that Macaulay makes no attempt to define the limits within which the government may thus provide for the good of society. These may be said to have been the views of Liberal politicians and Utilitarian churchmen. On the other hand, the religious theory of government, as expounded in Dr Arnold's Oxford *Lectures on History*, is based on the conception that the ideal church and state are one. Here there can be no bounds to the legitimate action of the state except its conformity with religious truth. And Dr Arnold does not hesitate to forecast an ideal state of society in which disbelief in the Christian religion shall so outrage the moral sense of the community that it may fittingly be put down by the strong arm of the law. The weakness of all theological speculations about government is that they are fitted only for local use. The theory of government cannot well be discussed to much purpose with a disputant who requires a series of the logical propositions to be taken for granted.

The Laissez-faire Theory.—Mill—A more profitable line of inquiry has been followed by writers of the economic school. The most important of these is John Stuart Mill, whose essay on *Liberty*, together with the concluding chapters of his treatise on *Political Economy*, gives a tolerably complete view of the principles of government. The leaning of political economists is towards what is called the *laissez-faire* or non-interference doctrine. There is a general presumption against the interference of Government, which is only to be overcome by very strong evidence of necessity. Governmental action is generally less effective than voluntary action. The necessary duties of Government are so burdensome, that to increase them destroys its efficiency. Its powers are already so great that individual freedom is constantly in danger. As a general rule, nothing which can be done by the voluntary agency of individuals should be left to the state. Each man is the best judge of his own interests. But, on the other hand, when the thing itself is admitted to be useful or necessary, and it cannot be effected by voluntary agency, or when it is of such a nature that the consumer cannot be considered capable of judging of the quality supplied, then Mr Mill would allow the state to interfere. Thus the education of children, and even of adults, would fairly come within the province of the state. Mr Mill even goes so far as to

admit that, where a restriction of the hours of labour, or the establishment of a periodical holiday, is proved to be beneficial to labourers as a class, but cannot be carried out voluntarily on account of the refusal of individuals to co-operate, Government may justifiably compel them to co-operate. Still further, Mr Mill would desire to see some control exercised by the Government over the operations of those voluntary associations which, consisting of large numbers of shareholders, necessarily leave their affairs in the hands of one or a few persons. In short, Mr Mill's general rule against state action admits of many important exceptions, founded on no principle less vague than that of public expediency. The essay on *Liberty* is mainly concerned with freedom of individual character, and its arguments apply to control exercised, not only by the state, but by society in the form of public opinion. The leading principle is that of Humboldt, "the absolute and essential importance of human development in its richest diversity." Humboldt broadly excluded education, religion, and morals from the action, direct and indirect, of the state. Mill, as we have seen, conceives education to be within the province of the state, but he would confine its action to compelling parents to educate their children.

Herbert Spencer.—The most distinguished opponent of state action, however, is Mr Herbert Spencer. In his *Social Statics*, published in 1850, he holds it to be the essential duty of Government to *protect*—to maintain men's rights to life, to personal liberty, and to property, and the theory that the Government ought to undertake other offices besides that of protector he regards as an untenable theory. Each man has a right to the fullest exercise of all his faculties, compatible with the same right in others. This is the fundamental law of equal freedom, which it is the duty and the only duty of the state to enforce. If the state goes beyond this duty, it becomes, not a protector, but an aggressor. Thus all state regulations of commerce, all religious establishments, all Government relief of the poor, all state systems of education and of sanitary superintendence, even the state currency and the post-office, stand condemned, not only as ineffective for their respective purposes, but as involving violations of man's natural liberty. Many of the principles enunciated in this book are not reconcilable with the later views of the author, but he would still appear to maintain his theory of government to the fullest extent. Thus, in the *Principles of Sociology*, published in 1877, he distinguishes between the militant type of society and the industrial type. The former is founded on the principle of compulsory co-operation, while the latter is framed on the principle of voluntary co-operation. He vaguely indicates "a possible future social type, differing as much from the industrial as this does from the militant, a type which, having a sustaining system more fully developed than any one known at present, will use the products of industry neither for maintaining a militant organization nor exclusively for material aggrandizement, but will devote them to the carrying on of higher activities." Of the two actually existing types, the militant is distinguished by a strong and the industrial by a feeble Governmental system. Reverting the analogy suggested by individual organisms, he holds the latter to be a higher and better type than the former.² And he maintains that military activity in a state distinguished by a high degree of industrial development produces a recurrence to the militant type of institutions generally. Thus, in Germany, the dealings of Bismarck with the ecclesiastical powers, and the measures taken for

² *Principles of Sociology*, vol. 1, London, 1877. In a postscript to part II Mr Spencer explains the "origin of this seeming incongruity." Individual organisms, high or low, have to maintain their lives by offensive or defensive activities on both, social organisms, except during the militant stage of their evolution, have to maintain

² *Critical and Historical Essays*, vol. 1.

centralizing the state control of railways, are instances of a more coercive *regime* established by war. In England, the peaceful period from 1815 to 1850 is contrasted with the militant period since 1850. The latter has been marked by the usurpations of military officialism, by sanitary dictation, by coercive philanthropy, by compulsory education, by an unhesitating faith in state judgment, and by a general disregard of the principles of free government, even on the side of the party which in the previous period effected changes in the direction of freedom.

Tendency of recent Legislation.—Turning from political theory to political practice, let us see how the legislation of the last fifty years in England has drawn the line between legitimate and illegitimate state action. The period that has elapsed since the passing of the Reform Act of 1832 has been one of great legislative activity. In no former period has legislation been so completely under the control of public opinion, or so directly affected by open discussion of the principles of projected measures. It will be of some interest, therefore, to inquire how the most enlightened political community in the world has, during the period of its fullest freedom, defined the business of government.

Reduction of State Action.—*Religion*.—The cases in which Government interference has been abolished or greatly limited during this period are mainly two—in matters of opinion (especially religious opinion), and in matters of contract. The principle that the state ought to maintain some form of religion has been surrendered by the disestablishment of the Irish Church. The disqualifications, political and civil, of dissenters, have, with a very few and not very important exceptions, been removed. The last remnant of the old rule, making witnesses incompetent on religious grounds, was removed by the Act enabling persons to give evidence without an oath. A few statutes making various forms of irreligion punishable still remain, but they are never enforced, and any attempt to enforce them would almost certainly end in their formal repeal. State prosecutions for expression of opinion have almost entirely ceased, and practically the only instrument of control now left is the law of libel. Under the influence of the judges, that law has, during the period in question, been uniformly interpreted in a sense favourable to the freedom of discussion. One of the few remaining restrictions on religious freedom is the principle, acted on in several recent cases, that a contract may be broken if its object is to facilitate the expression of irreligious opinions.¹

At the same time there appears to be a tendency to distinguish between merely irreligious opinions and opinions pronounced to be immoral. Convictions have lately been obtained for publishing and selling books advocating opinions on certain moral and social questions which appeared to a jury to be calculated to deprave the morals of the people. But here again the distinction has been authoritatively drawn between such views when presented in a scientific form, and adapted to a scientific audience, and the same views offered openly to the unscientific public. Utterable as such distinctions are, they manifest a tendency on the part of the courts to confine the prosecution of opinion within the principle of the law against indecent publications. It may further be added that, with one notable exception,—the Public Worship Regulation Act,—the dealings of the state with the church have been confined within a very narrow compass. The endowment of new sees, for instance, although sanctioned by the state, is left to the voluntary contributions of the public.

Contract.—Freedom of contract, in general, has been greatly advanced by the success of the free-trade agitation in 1843, which was not so much a protest against state regula-

tion as a demand for a cheap supply of food. Since that time, the principle that the state should leave men to make what bargains they please, without attempting to encourage any particular industry or to favour any special class, has taken rank as a maxim of universal application. One class of contracts—those between master and servant—long remained an exception to the general rule. Breach of such contracts by the servant was treated as a criminal offence, and the combination of servants to obtain a rise of wages as a conspiracy. A series of statutes, the last of which was passed a few years ago, has abolished the criminal character of the breach of the contract of service, except in a few cases. The abolition of the laws against usury in 1857 is another instance, the authorisation of trading companies with limited liability is another. The last great legislative measure before parliament (the Criminal Code Bill of 1879) proposes to do away with the old offences of maintenance and champerty. Besides the classes regarded by law as under disability to contract (infants, lunatics, and married women), a few doubtful instances of protected persons might still be named. Thus expectant heirs are treated in the spirit of the old laws against usury. Seamen are not allowed to make a charge upon their wages. In certain employments specified in the Truck Act wages are not allowed to be paid otherwise than in coin. The principle of free trade is outraged in its own name by the legal rule which invalidates contracts made "in restraint of trade."

Incursion of State Action.—The enumeration of new restrictive measures, and instances of increased state interference within the same period, would occupy a much more formidable list. A rough classification only will be here attempted. We shall take first, interference for the protection of definite classes of persons.

Education of Children.—This is perhaps the most conspicuous, as it is certainly the most beneficial and the least disputed, of the recent encroachments of the state. This progress of opinion and legislation on this subject has been singularly rapid. Beginning with Government grants in aid of education, strenuously resisted on grounds going to the very root of the question of legitimate state interference, the system has now culminated in a network of state supported and state-administered schools spread over the whole country. That the state should compel parents to educate their children would only be a slight departure, if any, from the general principle imposing duties on parents and disabilities on children. Under the present system the state not only compels the parent to educate, but itself provides, and in great measure pays for, the education. A generation of discussion has, however, drawn very distinctly the line beyond which this advance of state authority must not proceed. Compulsory state education is for children only, and may be justified by the general argument which justifies state protection to the helpless, it is elementary only, and it is secular only.

Regulation of the Labour of Children and Women.—The long series of Factory Acts is the best example of the steady and persistent advance of Government control in this direction. Here the line of protection is considerably advanced, but is again carefully drawn under male adults, although these of necessity share in the benefits of the protection in all employments where their work requires the co-operation of women and children. See FACTORY ACTS.

Regulation of Dangerous Employments.—Of these the Mines Regulation Acts are perhaps the best example. Here the Government actually lays down the rules under which alone these employments are suffered to be carried on. Here the principle that adults are capable of looking after themselves is overruled by the dangerous character of the employment.

In all these cases the action of the state is defended on

¹ E.g. a contract to let a hall for a lecture advocating atheistic principles.

the ground that the persons protected are unable sufficiently to protect themselves, and the principle adopted is that of prevention instead of mere punishment for breach of duty. Hence an enormous army of inspectors is required for the work of control.

Another class of interferences is justified on the ground of *public health*, and these, in respect of the amount of state intervention required, stand next to the protective measures already enumerated. The common law of nuisance recognizes the principle that any source of contagion or discomfort set up by an individual is an injury to those who may be affected by it, which they may call upon the state to suppress. The Sanitary Acts interpose the remedy at an earlier stage, and by the usual apparatus of Government inspectors and detectives. The largest measure on this subject is the Public Health Act, and the most extensive development of the principle is the lending of money by the Government to municipalities for the erection of healthy dwelling houses for labourers. Personal freedom is more directly affected by measures like the Vaccination Act, for which, however, the double ground of the helplessness of the subjects and the prevention of danger amounting to nuisance may be taken. The least defensible of all the measures of this class are those relating to the adulteration of various kinds of food. The fraudulent or negligent supply of food injurious to health is an injury which may be appropriately punished by an award of compensation to the person injured, and inflicting punishment on the delinquent. But under the last Act (Sale of Food and Drugs Act, 1875) it is a criminal offence to sell goods of a quality not asked for, and the usual staff of analysts and inspectors is established to facilitate detection. The mighty engine of Government determines the exact percentage of water which the dairyman may put in his milk and the publican in his gin.

Next come the cases in which the Government either aids or itself undertakes works of *public convenience*. The state monopoly of the post office is the most conspicuous example, and we have recently seen it extended by the acquisition of the telegraphs. Less directly the state has acquired control of the locomotive system, by granting compulsory powers of various sorts and a partial monopoly to railway companies, and by imposing certain regulations on them. This department of state activity has been greatly increased by the operations of the Public Works Loans Commission, which lends money to local bodies for such purposes as the erection of baths and wash houses, improving rivers, harbours, and towns, building light-houses and public libraries, and the like.

The assertion of state control over *endowments* is another wicked feature of the period. Except in this way, Government has not, in England at least, interfered with the higher sort of education to any great extent. But most of the endowed schools and the universities have been subjected to inquiry, and remodelled according to what are understood to be the demands of the age. Almost every kind of corporation has been revised in the same way, the most notable and scandalous exception being the numerous and wealthy corporations of the city of London. The history of these reforms reveals a perfectly clear *rationale* of the relations existing between an endowed institution and the state. All endowments are privileges created by the state in the way of exception to the universal rule of law against perpetuities—the rule which limits the operation of dead men's wills, and makes each generation master of its existing resources. When the purposes of an institution cease to be useful, or its organization is seen to be defective, it is the right and duty of the state to withdraw the privilege altogether, or continue it under new conditions. All endowments become, in virtue of this rule, the property of the state, and how it shall deal with them becomes a

question of statesmanship, not of interference with private interests. Under the name of vested interests, "all existing rights of individuals are shakingly touched. These two correlative principles—the right of the state to revise all endowments, and the obligation to respect vested interests in any such revision—have ceased to be disputable in English politics.

A similar extension of state control is to be seen in the organization of the *professions*—*i.e.*, persons licensed to practice particular arts. The church, like the army, is not, properly speaking, a profession, and its regulations belong to the same class as those of the army or the civil service. The true professions are the various grades of lawyers and medical men. They have an exclusive monopoly of the arts which they profess. The protection of this monopoly was long the only connection between them and the Government. They were left to the management of self-governing societies or corporations. Within our own generation there has been, not only a marked increase of state control over the professions, but a marked tendency to extend it to occupations hitherto uncontrolled. The system of medical licentiate is years by year becoming more stringent and more centralized. A recent Act provides for the more efficient testing of the qualifications of solicitors. The bar, which has hitherto with immense practical wisdom governed itself by means of voluntary societies, is threatened with a parliamentary constitution, settling the conditions of admission, examination, discipline, and dismissal. The free professions are demanding the like recognition and supervision by the state. A bill is now (1874) before parliament for organizing the professors of schoolmasters in the higher class of schools, and elementary schoolmasters are claiming to be included in its scope. The business of buying and selling stocks and shares has narrowly escaped, if it has escaped, the rules and regulations of an act of parliament. A commission was actually appointed a few years ago to investigate the practices of brokers and jobbers, and one of its recommendations was that the Stock Exchange should forthwith become a corporation. The last interference of this sort was the appointment of a committee of the House of Commons, at the instance of the London retail trader, to inquire into the working of what are called co-operative stores. Inquiry does not of course imply interference, and a committee or a commission is often a convenient way of stopping the mouths of agitators whom it might not be convenient to ignore altogether. Futile as the remedy may be, the first thought of every aggrieved class is to lay its wings before parliament.

Protection of things from Excessive Consumption.—Another class of interferences may be described, in the most general terms, as measures taken for the protection of things which would otherwise perish, or greatly diminish, by reason of excessive use. Statutes of this sort have greatly multiplied during the last fifty years. There is hardly any kind of animal, which men think worth catching or eating, without its statutory close time. The ostensible reason for this kind of legislation is that salmon, let us say, or oysters, are a very important article of food, and unless men are restrained from pursuing them to excess, the whole breed would ultimately be extinguished, or so reduced in number as to be of little use. Another and less avowed reason is that animals of the protected order are necessary for the recreation of a certain class of gentlemen, who, in the interests of their own pleasures, must be restrained from carrying them to excess. Thus no gun must be lifted against grouse before the 12th of August, or against partridge before the 1st of September, so that next year these may still be grouse and partridges in the land. The great majority of these enactments belong in spirit to the

game law, but many of them are genuinely intended for the perpetration of pernicious supplies of food. Some of them, like the Sea-birds Protection Act, or the Small Birds Protection Act, are dictated by some sentimental fear of the extinction of such animals. As a whole, they are among the least desirable of the modern extensions of state power.

Coercion for Moral Purposes.—The measures hitherto noticed may in general be justified either on the ground of the inability of the persons protected to help themselves, or on the ground that some good to society as a whole, or to large portions of it, is secured thereby. Another class of measures openly aims at the moral improvement of the individuals affected by them, and in this class there has been an amazing and alarming increase. The laws against gaming are one of the best examples. At common law a wager was a contract enforceable by the tribunals like any other. Not content with declining to enforce wagers, the state went further, and tried to put them down altogether. It made lotteries illegal. It visited with heavy penalties the keeping of betting-houses, all betting in public places the publication of betting lists, &c. Games which lead to betting are put under the restraint of a licensing system, and in some parts of the provinces the state orders its citizens not to play billiards after eleven o'clock at night. To this class belongs the severe code regulating what is called the liquor traffic. Through the agency of licensing magistrates, the state fixes all limits the number of public-houses, then it dictates directly the hours during which liquor may be bought and sold, and in Scotland and Ireland it goes further, and prohibits altogether the sale of liquor on Sunday. A committee of the House of Lords has touched the highest point of government control in proposing to empower local authorities to buy up all the public houses in their districts, and carry on the business for themselves. There is a simultaneously increasing tendency to interfere with people's amusements. Fairs are being put down as immoral, music and dancing require licences very strictly granted, the gipsy of the lord chamberlain over the London theatres is tightened, and so on. The course of moral legislation, in fact, threatens to sweep away every barrier to the encroachments of the state. The extended range of Government interference in other things has been accompanied, as we have seen, by a very distinct recognition of limits, either in the rights of the individual conscience, or in the capacity of adult manhood to manage its own affairs. But Acts of Parliament for improving the moral characters of men seem to recognize no limit at all. And it is a singular fact that, while this kind of legislation, under existing social arrangements, fails to affect the well-to-do classes, and passes chiefly on the comparatively poor, it is becoming more and more identified with the popular party in politics, and gathers strength with every addition to the popular element in government.

We have hitherto confined our attention to simple as opposed to compound forms of government, and to the supreme as opposed to the subordinate functions of government. The complete treatment of the subject would require us to take some notice of the (1) association of several communities, with separate governments under one sovereignty, and (2) of the subordinate organizations for carrying on the government of localities, under the supreme government.

1. *Federal Government.*—As this is the subject of a separate article (vol. 1, p. 61), we need only notice here the case in which one of the associated Governments is the ultimate seat of sovereign power—the others being its colonies or dependencies. England is, of course, by far the most illustrious example of a country so situated, and her relations with the subordinate communities exhibit much variety of form. One leading distinction may be

drawn—namely, between the communities which are allowed to govern themselves and those which, either as being unfit for self government, like India and Egypt, or on account of the military necessities of the situation, as Malta and Gibraltar, are governed by the officers of the English Government. In the subject dependencies, as the latter may be called, the government is usually carried on by a governor and council, nominated by the crown, and holding office for various terms of years. The council, as a general rule, consists of the highest officers of the dependency, such as the chief justice or the attorney general. The governor and council are strictly the delegates of the home Government and have no legal or constitutional status of their own. The recently acquired island of Cyprus occupies an anomalous position in the British state system. The English Government holds it, not as sovereign, but as lieutenant general of the sovereign, the sultan of Turkey. The government of the island is vested in a commissioner who takes his orders, not from the colonial, but from the foreign office. As a general rule the relations between the mother country and her dependencies lie under the charge of a special department of state—the colonial office.

In free dependencies the alternative is between some kind of confederation with the mother country, whereby the dependency shall have a representative vote in the supreme government and the practical independence of the dependency in all but international affairs. In the French system the deputies of Algiers and other colonies sit in the supreme legislature along with the other representatives of France. In the English system distance alone would render such a scheme impracticable, and, even where distance would be little or no hindrance, there has been no desire on either side for any such connexion. Dependencies like the Isle of Man and the Channel Islands are as completely separated from England as New Zealand and Canada. The free dependencies have local constitutions framed on the model of the home Government—free chambers of legislation, governor nominated by the crown, and a ministry dependent on parliament. The governor is supposed to stand to the ministry and parliament as the crown to the ministry and parliament at home, but it is to be remembered that the governor is, properly speaking, the representative not of the English crown but of the English Government. It is from the colonial secretary that the governor takes his instructions, and the colonial secretary and his colleagues take their instructions from the House of Commons. And, just as the practice of the constitution has made it impossible for the monarch to resist the will of parliament, so it is established that the governor, as representing England, shall not veto enactments of the colonial legislature. Just as in England the House of Commons invariably determines the fate of a ministry, so does the lower or popular house in a colonial legislature. It is needless to say that this is a very great advance on the old theory of colonial relations. Beginning in special grants or charters granted to individuals or corporations, the English colonies in North America held their liberties by the grace of the crown. The successful revolt of the colonies taught the mother country the folly of supposing that Englishmen in America would consent to be governed by Englishmen at home.

Although colonial institutions are modelled as nearly as may be after the original type, they are not entirely free from questions of fundamental difficulty. The central question of government—Whose will is to prevail?—has, at the present time (1879) been agitated by one of the greatest of the colonies, a deadlock between the council and the assembly in Victoria being referred to England, and the governor-general of Canada refusing to dismiss a lieutenant-governor on the advice of his responsible ministry.

The subjection of colonies to the home Government is still retained in two important cases. The colonies have no voice whatever in determining the nature of their relations with other communities, the question of peace or war is decided for them by the home Government. Again, all the colonies, whatever may be their powers of local self government, seek justice in the last resort from the sovereign in council.

2 Local Government.—As the business of society at large must be undertaken by the supreme government, so the local business of the subdivisions of society must be undertaken by local subgovernment. Local government rests on a small scale the features of the supreme government, but its business is chiefly judicial and administrative. The most marked distinction here is between rural and urban communities—between the county and the borough. Self-government or representative government is the rule in the latter, the exception in the former. In England, since the Municipal Corporations Act, the affairs of all urban communities, except the city of London and a few unimportant boroughs, are managed by the direct representatives of the inhabitants. In the counties the control of affairs rests with the justices of the peace, who are nominated by the crown exclusively from the class of gentry.

The degree of control exercised by the supreme government over local governments is a point of first-rate importance in the constitution of a country. Among free countries England and France stand at opposite ends of the scale,—England being characterized by great local independence, France by strict central control. Thus it is said that, even under the republic, the minister of education can say that at a given hour all the children in all the schools of France are learning the same lesson. The habitual dependence of the French people upon the action of the state has been described as a survival from the times of imperial despotism which may be expected to disappear gradually under the influence of freedom. A step in this direction has certainly been taken in the proposal to allow communes to elect their own *maires*, and the abuse of the prefectural system by a recent ministry ought to lead to some diminution of its enormous powers. On the other hand the increased activity of the state, which, as we have already seen, has accompanied the establishment of popular government on a wide basis in England, has shown itself also in increased centralization. The new functions—educational, sanitary, and others—imposed on local bodies are controlled by the supreme government through central boards. In 1871 the local government board was constituted to take over the powers of control over local boards hitherto exercised by various high officers of state, the post law board, and the privy council. More recently the Prison Act of 1877 has transferred to the secretary of state the powers hitherto exercised by the local prison authorities, and has made the cost of maintaining local prisons a burden on the public funds.

As we have already said, the work of local governments generally embraces very little that can properly be called legislation. They have a power of making bye-laws for carrying out within their district the purposes of a general law, and over that power the courts of justice exercise a vigilant control. Parliament in England has hitherto looked with great distrust on subordinate legislatures, and it is a common saying that the jealousy of the House of Commons is one of the reasons why the metropolis remains without municipal government. But it would now be generally admitted that the legislation demanded of parliament every year is greatly beyond its effective powers. There are indications of an approach to something that may be described as home rule—a name which inspires more distrust than the reality. Parliament makes no pretence of consistency

in legislation, separately for England, Scotland, and Ireland. To take only notorious examples,—the Irish Land Act, the Disturbance Act, and the Sunday Liquor Act of Ireland, and the Forbes Mackenzie Act of Scotland are instances of legislation according to the supposed wishes of the people specially affected. Irish and Scotch business transacts in the House of Commons more and more to fall into the hands of Irish and Scotch members, and the interference of others is not infrequently resented as an intrusion. Again, private bill legislation, regulated as it is by ascertained general principles, has come to be in fact, as in form, a purely judicial proceeding, which might well be relegated, as it no doubt one day will be relegated, to local tribunals. At other indications of the same tendency is to be found in what is called permissive legislation, which leaves to local authorities the responsibility of deciding how far a given principle shall be applied. (R.N.)

GOWER, JOHN (1325?-1408), one of the best of the English minor poets, was born in or about the year 1325, but the date is not exactly known. It has been conclusively shown by Sir Harris Nicolas that he belonged to the county of Kent. His family was wealthy, and he seems to have had various country houses. So far as we know he did not marry till 1397, when he was said to be Agnes Groundolf. He was an intimate friend of Chaucer's, but there is no evidence to prove that they were fellow-students. A few years after his marriage, Gower became blind, and had to give up writing. He spent his declining years in the priory of St Mary Overes, or, as it is now called, St Saviour's, in Southwark, where his monument is still to be seen.

Near the close of the *Confessio Amantis*, Gower puts the following compliment to Chaucer into the mouth of Venus—

"And greet wel Chaucer when ye meet,
As my disciple and my poet;
For in the flower of his age
In sundry wise, as he wold couthe
Of dithes and of songes glade,
The which he for my sake made,
The land fulfilled is over all," &c.

In these lines he was merely requiting a compliment that had been paid him some years before by his brother poet, who, in dedicating to him his *Trilogia* and *Cressida*, addressed him as "O moral Gower," an epithet which, though not remarkably happy, has stuck to him. Gower died in 1408. In his will he leaves a number of religious legacies to various ecclesiastical persons and institutions, and £100, along with the rents of his manors, to his wife Agnes. The beautiful church in which Gower lies was rebuilt in great part at his expense, and proves, among other things, that he must have been exempt from one of the usual misfortunes of poets—poverty.

Gower's poetical works are four in number.—*Balades and other Poems*, in French, printed in 1818 for the Roxburghe Club, the *Speculum Malicieus*, a treatise on the duties of married life, written in French verse, and divided into ten books, the *Confessio Amantis*, a narrative in Latin elegiacs, of the insurrection of the commons in the reign of Richard II, and the *Confessio Amantis*. The second of these works is believed to have perished, of the third there is a good edition by the Rev H. O. Cox, printed for the Roxburghe Club in 1850, and the fourth was first printed by Caxton in 1483. The *Confessio Amantis*, or Lover's Confession, is a huge miscellaneous collection of physical, metaphysical, and moral reflections, and of stories called from the common repertoires of the Middle Ages. A kind of unity is given to these apparently incongruous materials by the form of the poem, which is a dialogue between a lover and his confessor, who is a priest of Venus, and is called Genres. In the moral part of his theme, Gower is confessedly wise, impressive, and sometimes almost

sublime. But, as Ellis, in his *Specimens of the Early English Poets*, observes, "His narrative is often quite penitizing, and when we read in his works the tales with which we have been familiarized in the poems of Ovid, we feel a mixture of surprise and despair at the poet's industry in removing every detail on which the imagination had been accustomed to fasten. The author of the *Uranian Phoenix* was a poet, and at least sufficiently fond of ornament. Gowr considers him as a mere naturalist, scrupulously preserves his facts, relates them with great perspicuity, and is fully satisfied when he has extracted from them as much morality as they can reasonably be expected to furnish." As Professor Lowell has well remarked, "from his positively raised tenderness to the precision of a science." Though his descriptions are often extremely agreeable, and his diction easy and smooth, his prolixity, and the poetic feebleness of the conceptions, will prevent the *Lower's Confession* from ever rivaling the writings of Chaucer, or even approximating them in popularity.

See Todd, *Illustrations of the Lives and Writings of Geoffrey Chaucer*; Ellis's *Specimens of the Early English Poets*, *Chaucer's First Life*; Watson's *First Biography*; Colman's *Life of Chaucer*; Morley's *English Poets*; St. John's *Life of Chaucer*; Mrs. Norton's *Three Centuries of English Poetry*; *Biographical Review* for 1823, where Sir Henry Halliwell throws much light on the subject; *Observations on the Language of Chaucer's Works*, by F. J. Child; *Marino's Characteristics of English Poets*, and, above all, Dr. Rumbold Pauli's wholly edition of the *Confessio Amantis* (London, 1857), which contains a notice of Gowr, and an account of the MS. and editors of the poem.

GOYA, a town of the Argentine Republic, in the province of Corrientes, near the junction of a small stream with the Paraná, about 100 miles S of Corrientes. The streets are about 60 feet wide, and the houses, built of brick, are often two stories high. One side of the handsome plaza is occupied by a large church erected by local subscription, and in the centre there is a pyramid 50 feet high. Hides, wool, cheese, and oranges, are the principal articles of trade, the cheese especially finding a good market at Buenos Ayres and elsewhere. The town was founded in 1807 by the national Government, and is said to have derived its name from Goya or Gogoya, the wife of the Portuguese cattle-farmer who was formerly settled on the spot. The population, which includes a large foreign element,—Italians, Basques, and French,—amounted to 10,907 in 1869. See Mulholland's *Handbook of the River Plate*.

GOYANNA, a city of Brazil, in the province of Pernambuco, on a river of its own name, about 10 miles from the sea. It is a well-built place, and carries on a trade in cotton, sugar, rum, hides, timber, dye-stuffs, oils, and other products of the fertile region in which it lies. Most of its exports are sent to Recife for shipment, its own port being only deep enough for the larger class of coasting vessels. The population is about 12,000.

GOYA Y LUCIENTES, FRANCISCO (1746–1829), Spanish painter, was born in 1746 at Fuendetodos, a small Aragonese village near Saragossa. At an early age he commenced his artistic career under the direction of José Luzán Martínez, who had studied painting at Naples under Masaccio. It is clear that the accuracy in drawing Luzán was said to have acquired by diligent study of the best Italian masters did not much influence his erratic pupil. Goya, a true son of his province, was bold, capricious, headstrong, and obstinate. He took a prominent part on more than one occasion in those rival religious processions at Saragossa which often ended in unseemly fights, and his friends were led by him in consequence to despatch him in his nineteenth year to Madrid, where, prior to his departure for Rome, his mode of life appears to have been anything but that of a quiet orderly citizen. Being a good musician, and gifted with a voice, he sallied forth nightly, serenading

the caged beauties of the capital, with whom he seems to have been a very general favourite.

Lacking the necessary royal patronage, and probably scandalized by his mode of life the senate court officials he did not receive—perhaps did not seek—the usual honoriarium accorded to those students who visited Rome for the purpose of study. Finding it convenient to retire for a time from Madrid, he decided to visit Rome at his own cost, and being without resources he joined a "quadilla" of bull fighters, passing from town to town until he reached the shores of the Mediterranean. We next hear of him teaching Rome, broken in health and financially bankrupt. In 1772 he was awarded the second prize in a competition initiated by the academy of Parma, styling himself "pupil to Dayen, painter to the king of Spain." Compelled to quit Rome somewhat suddenly, he appears again in Madrid in 1775, the husband of Dayen's daughter, and father of a son. About this time he appears to have visited his parents at Fuendetodos, no doubt noting much which later on he utilized in his graphic works. On returning to Madrid he commenced painting canvasses for the tapestry factory of Santa Barbara, in which the king took much interest. Between 1776 and 1780 he appears to have supplied thirty examples, receiving about £1200 for them. Soon after the revolution of 1808, an official was appointed to take an inventory of all works of art belonging to the nation, and in one of the cellars of the Madrid palace were discovered forty three of these works of Goya on rolls forgotten and neglected (see *Los Tàpices de Goya, por Ochoa y Villanueva*, Madrid, 1870).

His originality and talent were soon recognized by Menzies, the king's painter, and royal favour naturally followed. His career now becomes intimately connected with the court life of his time. He was commissioned by the king to design a series of frescos for the church of St Anthony of Florida, Madrid, and he also produced work for St. Agosteo, Valencia, and Toledo. Ecclesiastical art was not his forte, and although he cannot be said to have failed in any of his work, his fame was not enhanced by his religious subjects.

In portraiture, without doubt, Goya excelled his portraits are evidently life-like and unexaggerated, and he disdaind flattery. He worked rapidly, and during his long stay at Madrid painted, amongst many others, the portraits of four sovereigns of Spain—Charles III and IV, Ferdinand VII, and 'King Joseph.' The duke of Wellington also sat to him, but on his making some remark which raised the artist's choler, Goya seized a plaster cast and hurled it at the head of the duke. There are extant two pencil sketches of Wellington, one in the British Museum, the other in a private collection. One of his best portraits is that of the lovely Andalusian duchess of Alva. He now became the spoiled child of fortune, and acquired, at any rate externally, much of the polish of court manners. He still worked industriously upon his own lines, and, while there is a stiffness almost ungainly in the pose of some of his portraits, the stern individuality is always preserved.

Including the designs for tapestry, Goya's graphic works are numerous and varied, both in style and feeling, from his Watteau-like *Al Fresco Breakfast*, *Romantico de San Isidro*, to the *Chute* feeding the Devil's Lamp, the *Monon del Gallo*, and the painfully realistic massacre of the *Des de Mayo* (1808). Goya's versatility is proved, too, in his hands the pencil, brush, and graver are equally powerful. Some of his crayon sketches of scenes in the bull ring are full of force and character, slight but full of meaning. He was in his thirty-second year when he commenced his sketches from Velasquez, whose influence may, however, be traced in his work at an earlier date. A careful e-

animation of some of the drawings made for these etchings indicates a steadiness, of purpose not usually discovered in Goya's craft as draughtsman. He is much more widely known by his etchings than his oils, the latter necessarily must be sought in public and private collections principally in Spain, while the former are known and prized in every capital of Europe. The etched collections by which Goya is best known include *Los Caprichos*, which have a satirical meaning known only to the few, they are bold, ward, and full of force. *Los Proverbios* are also supposed to have some hidden intention. *Los Desastres de la Guerra* may fairly claim to depict Spain during the French invasion. In the bull fight series, Goya is evidently at home; he was a skilled master of the barbarous art, and no doubt every sketch is true to nature, and from life.

Goya resided from Madrid, desiring probably during his later years to escape the trying climate of that capital. He died at Bordeaux in his eighty-third year, and a monument has been erected there over his remains. Whether his influence produced the art of Fontuyn and the modern Spanish school may be matter for discussion, but, from the death of Velasquez and Murillo to the advent of Fontuyn, Goya's name is the only important one found in the history of Spanish art. Paul Lefort and Truette may be consulted for fuller details of his life and works.

GOYAZ, formerly called *Villa Boa* de Goyaz, the chief town of the province of Goyaz in Brazil, in the valley of the auriferous Velmalho, a right-hand tributary of the Araguaia. It lies about 650 miles N.W. of Rio de Janeiro, and 700 miles S.W. of San Salvador. As a bishop's see, the seat of the provincial assembly, and the residence of a civil president and a military governor, it is a place of considerable importance, and with its broad streets, wide squares, and well built houses it ranks as one of the most attractive towns of Brazil. The public buildings comprise the legislative chambers, a court-house, a hospital, a prison, an institution for the as-saying of gold, and a municipal slaughter-house. Goyaz was founded in 1736 under the name of Santa Anna, and it received its present designation about three years later when it was raised to the rank of a city. The population is about 8000.

GOYEN, JAN JOSEPH ZOOM VAN (1896-1856), was born at Leyden on the 13th of January 1596, learned painting under several masters at Leyden and Haarlem, married in 1618, and settled at the Hague about 1631. One of the few Dutch painters who failed to captivate English taste, his influence was great on Dutch art, and he was one of the first to emancipate himself from the traditions of minute imitation embodied in the works of Breughel and Savery. Though he preserved the dull scale of tone peculiar to those painters, he studied atmospheric effects in black and white with considerable skill. He formed Solomon Ruysdaal and Pieter Potter, forced attention from Rembrandt, and bequeathed some of his precepts to Pieter de Molyn, Colenbier, Safleven, Van der Kabel, and even Berghem. His life at the Hague for twenty-five years was very prosperous, and he rose in 1640 to be president of his guild. A friend of Van Dyck and Bartholomew van der Helst, he sat to both these artists for his likeness. His daughter Margaret married Jan Steen, and he had steady patrons in the stadtholder Frederick Henry, and the chiefs of the municipality of the Hague. He died at the Hague in 1655, possessed of land and houses to the amount of 15,000 florins.

Between 1610 and 1616 Van Goyen wandered from one school to the other. He was first apprenticed to Isaac Swaneburgh, he then passed through the workshops of De Man, Klok, and De Hoon. In 1616 he took a decisive step and joined Esaias van der Velde at Harlem, amongst his earliest pictures, some of 1621 (Berlin Museum) and

1623 (Dunsmack Gallery) show the influence of Esaias very perceptibly. The landscape is minute. Details of branching and foliage are given, and the figures are important in relation to the distances. After 1625 these peculiarities gradually disappear. Atmospheric effect in landscapes of cool tints, varying from grey green to peal on brown and yellow dun is the principal object which Van Goyen holds in view, and he succeeds admirably in light skies with drifting misty cloud, and downs with cottages and scanty shrubbery or stunted trees. Neglecting all detail of foliage he now works in a thin diluted medium, laying on innuings as of sepia or Indian ink, and finishing without loss of transparency or lucidity. Throwing his foreground into darkness, he casts alternate light and shade upon the more distant planes, and realises most pleasing views of large expanse. In buildings and water, with slipping near the banks, he sometimes has the strength if not the colour of Albert Cuyp. The defect of his work is chiefly want of solidity. But even this had its charm for Van Goyen's contemporaries, and some time elapsed before Cuyp, who imitated him, rectified his method of transparent tinting to the foliage of foreground trees.

Van Goyen's pictures are comparatively rare in English collections. Unrepresented in the national galleries, he is seen to advantage abroad, and chiefly at the Louvre, and in Berlin, Godes, Vienna, Munich, and Augsburg. Twenty-eight of his works were exhibited together at Vienna in 1873. His panels fell in value during the 17th century, when they fetched prices as low as 10 and seldom as high as 100 florins. Now they are worth ten times more than in 1700. Though he visited France once or twice, Van Goyen chiefly confined himself to the scenery of Holland and the Rhine. Nine times from 1633 to 1655 he painted views of Dordrecht. Nimeguen was one of his favourite resorts. But he was also fond of Haarlem and Amsterdam, and he did not neglect Arnhem or Utrecht. One of his largest pieces is a view of the Hague, executed in 1651 for the municipality, and now in the town collection of that city. Most of his panels represent scenes of the Rhine, the Waal, and the Maese. But he sometimes sketched the downs of Scheveningen, or the sea at the mouth of the Rhine and Scheldt, and he liked to depict the calm inshore, and rarely ventured upon seas stirred by more than a curling breeze or the swell of a coming gale. He often painted winter scenes, with ice and skates and sledges, in the style familiar to Isaac van Ostade. There are numerous varieties of these subjects in the master's works from 1621 to 1653. One historical picture has been assigned to Van Goyen—the embarkation of Charles II. in the Dutch collection. But this canvas was executed after Van Goyen's death. When he tried this form of art he properly mistrusted his own powers. But he produced little in partnership with his contemporaries, and we can only except the Watering-place in the gallery of Vienna, where the landscape is enlivened with horses and cattle by Philip Wouvermans. Even Jan Steen, who was his son-in-law, only painted figures for one of his pictures, and it is probable that this piece was completed after Van Goyen's death. More than 250 of Van Goyen's pictures are known and accessible. Of this number little more than 70 are undated. None exist without the full name or monogram, and yet there is no painter whose hand it is easier to trace without the help of these adjuncts. Another, but a poor one, Van Goyen has only bequeathed to us two very rare plates.

GOZLAN, LEON, a French novelist and play writer, was born at Marseilles in 1803, and died in 1866. When he was still a boy, his father, who had made a large fortune as a ship-broker, met with adverse circumstances, and Léon, before completing his education, had to go to sea in order to earn a living. He went several trading voyages to Algiers

and to Senegal, without, it would seem, much profit. In the meantime his literary tastes gradually developed, and he abandoned mercantile pursuits for the modest employment of a teacher in Marseilles. He, however, did not remain long there, and in 1828 we find him in Paris, disclaimed to run the risks of literary life. His townsman, Joseph May, who was then making himself famous by his political satires, smoothed his way, and introduced him to several newspapers. But Gozzoli did not sacrifice literature to politics. Though he contributed many essays to the reviews, it is as a fertile and ingenious author of novels and plays that he is best known. His first novel was *Les Amours d'un apothicaire* (1828), and this was followed by numerous others, among which may be mentioned *Le Sirey de Chantilly*, *Arlette Fournier* (one of the most original and celebrated of his productions), *Les Nuits du Pair-Luisant*, *Le Tapis Vert*, *Georges III*, *La Folle du logis*, *La famille Lambert*, *Les Émotions de Polydore Alaviquin*, &c. His principal works for the theatre are—*La Grotte de Luit*, *La Pluie et le beau temps*, *Le Lion empaillé*, *Pied de Poi*, *Louise de Nanteuil*, *Le Gâteau des Reines*, *Les Prouesses de la Comtesse*, *Le Dumas et le Ferre*, and adaptations of several of his own novels to the stage. Gozzoli also wrote a romantic and picturesque description of the old mansions and mansions of his country, entitled *Les Châteaux de France*, 4 vols. (1841), and a biographical essay on the great novelist Balzac (1861). He was made a member of the legion of honour in 1846, and in 1859 an officer of third order. Louis Huret has published a sketch of his life.

Of the many novels which unfortunately dropped, as it were, from Gozzoli's pen during a period of thirty-eight years, very few have the qualities which commend a work of fiction to posterity, but nearly all are pleasant to read, and some will no doubt survive as an interesting and lively picture of French manners during the first half of this century. He holds an honourable place in the second rank of French novelists.

GOZZO. See MAZZI.
GOZZOLI, CARLO, COUNT (1732-1806), an Italian dramatist, was descended from an old Venetian family, and was born in March 1732. Compelled by the embarrassed condition of his father's affairs to procure the means of self support, he, at the age of sixteen, joined the army in Dalmanin, but three years afterwards he returned to Venice, where he soon made a reputation for himself as the virtuous member of the Giannelleschi society, to which the publication of several satirical pieces had gained him admission. This society, nominally devoted to conviviality and wit, had also serious literary aims, and was especially zealous to preserve the Tuscan literature pure and unaltered by foreign influences. The displacement of the old Italian comedy by the dimes of Chiari and Goldoni founded on French models threatened defeat to all their efforts, and in 1767 Gozzoli came to the rescue by publishing a satirical poem, *Parodia degli uffiziali per l'anno bisestile*, and in 1761 by his comedy, *Fiaba dell'amore delle tre melancolie*, a parody of the manner of the two obnoxious poets, founded on a fairy tale. For its representation he obtained the services of the Sackhi company of players, who, on account of the popularity of the comedies of Chiari and Goldoni—which afforded no scope for the display of their peculiar talents—had been left without employment, and as their satirical poems was thus sharpened by personal enmity, the play met with extraordinary success. Struck by the effect produced on the audience by the introduction of the supernatural or mythical element, which he had mainly used as a convenient medium for his satirical purposes, Gozzoli now produced a series of dramatic pieces based on fairy tales, which for a period obtained great popularity, but after the

breaking up of the Sackhi company were completely disregarded. They have, however, obtained high praise from Goethe, Schlegel, Madame de Staël, and Semanini; and one of them, *Le Tintadote*, was translated by Schiller. In his later years Gozzoli set himself to the production of tragic drama in which the comic element was largely introduced, but as this innovation proved unacceptable to the critics, he had recourse to the Spanish drama, from which he obtained models for various pieces which, however, met with only equivocal success. He died 4th April 1806.

His collected works were published under his own superintendence, at Venice, in 1793, in 10 volumes, and his dramatic works, translated into German by Werthes, were published at Bonn in 1795. See Gozzoli's work, *Memorie inedite della città di Chiari*, &c., vols. Venice, 1797, translated into French by Paul de Musset, Paris, 1848, 2^e édit., *Gesetz über die dramatische Kunst*, Venice, 1803, (Gherardini, *Vita di Gozzoli*, &c., 1831, "Charles" (works), by Paul de Musset, in the *Rivista dei Due Mondi* for 15th November 1814, and Magnan, *Carlo Gozzoli e la sua scuola*, Venice, 1869, a critical edition, 1876.

GOZZOLI, GASTRO, COUNT (1713-1786), oldest brother of Carlo Gozzoli, was born 4th December 1713. In 1739 he married the poetess Luise Beggalli, and she undertook the management of the theatre of San Angelo, Venice, he supplying the performances with dimes chiefly translated from the French. This speculation proved unfortunate, but meantime he had attained a high reputation for his contributions to the *Giornetta Veneta*, and he soon came to be known as one of the ablest critics and purest and most elegant stylists in Italy. For a considerable time he was censor of the press in Venice, and in 1771 he was appointed to reorganize the university system at Padua. He died at Padua, 26th December 1786.

His principal writings are *Osservazioni sulla Tragedia*, on the model of the English *Spectator*, and distinguished by its high tone and its light and pleasant style, *Lettere famigliari*, a collection of short literary pieces in prose and verse, on subjects of general interest, *Sonetti morali*, poems in blank verse after the manner of Horace, *Il mondo nuovo*, a representation of him in persons with numerous dialogues in the style of La Fontaine, and *Dialoghi di alcuni poeti sopra la moderna civiltà di Parigi*, a defence of the art of poetry against the attacks of Bettinelli. He also translated some works from the French and English, including *Memorie di Voltaire* and Pope's *Essay on Criticism*. His collected works were published at Venice, 1794-99, in 12 volumes, and several editions have appeared since.

GOZZOLI, BASSOZZO, an eminent painter, was born in Florence in 1421, or perhaps 1420, and in the early part of his career assisted Fra Angelico, whom he followed to Rome, and worked with at Orvieto. While in Rome, he executed, in the Cappella at Anagni, a fresco of St Anthony and two Angels. In 1419 he left Angelico, and went to Montefalco, near Foligno in Umbria. In St Fortunato, near Montefalco, he painted a Madonna and Child with Saints and Angels, and three other works. One of these, the altarpiece representing St Thomas receiving the Girdle of the Virgin, is now in the Lateran Museum, and shows the affinity of Gozzoli's early style to Angelico's. He next painted in the monastery of St Francis, Montefalco, filling the choir with a triple course of subjects from the life of the saint, with various accessories, including heads of Dante, Petrarch, and Giotto. This work was completed in 1463, and is still marked by the style of Angelico, crossed here and there with a more distinctly Giottoesque influence. In the same church, in the chapel of St Jerome, is a fresco by Gozzoli of the Virgin and Saints, the Crucifixion, and other subjects. He remained at Montefalco probably till 1466, employing Messeris as assistant. Thence he went to Perugia, and painted in a church a Virgin and Saints, now in the local academy, and soon afterwards to his native Florence, the headquarters of art. By the end of 1469 he had nearly finished his important labour in the chapel of the Palazzo Rucellai, the Journey of the Kings to Bethlehem, and, in the tribune of this chapel, a composition of Angels

in a Paradise. This picture in the London National Gallery, a Virgin and Child with Saints, 1461, belongs also to the period of his Florentine sojourn. Another small picture in the same gallery, the Rape of Helen, is of dubious authenticity. In 1464 Gozzoli left Florence for S. Gimignano, where he executed some extensive works, in the church of St Augustine, a composition of St Sebastian protecting the City from the Plague of this same year, 1464, over the entire choir of the church, a triple course of scenes from the legends of St Augustine, from the time of his entering the school of Augustine on to his burial, seventeen chief subjects, with some accessories, in the Pieve di S. Gimignano, the Martyrdom of Sebastian, and other subjects, and some further works in the city and its vicinity. Here his style combined something of Lippo Lippi with its original elements, and he received co-operation from Gherardo d'Andrea. He stayed in this city till 1467, and then began, in the Campo Santo of Pisa, from 1469, the vast series of mural paintings with which his name is specially identified. These are twenty-four subjects from the Old Testament, from the Invention of Wine by Noah to the Visit of the Queen of Sheba to Solomon. He contracted to paint three subjects per year, for about ten dracms each—a sum which may be regarded as equivalent to £100 at the present day. It appears, however, that this contract was not strictly adhered to, for the actual rate of painting was only three pictures in two years. Perhaps the great multitude of figures and accessories was accepted as a set off against the slower rate of production. By January 1470 he had executed the fresco of Noah and his Family, followed by the Curse of Ham, the Building of the Tower of Babel (which contains portraits of Cosimo de' Medici, the noble Lorenzo, Poliziano, and others), the Destruction of Sodom, the Victory of Abraham, the Marriage of Rebecca and of Rachel, the Life of Moses, &c. In the Cappella Ammannati, facing a gate of the Campo Santo, he painted also an Adoration of the Magi, wherein appears a portrait of himself. All this enormous mass of work, in which Gozzoli was probably assisted by Zanobi Macchiavelli, was performed, in addition to several other pictures during his stay in Pisa (we need only specify the Glory of St Thomas Aquinas, now in the Louvre), in sixteen years, lasting up to 1485. This is the latest date which can with certainty be assigned to any work from his hand, although he is known to have been alive up to 1496, if not afterwards. In 1478 the Pisan authorities had granted him as a token of their regard, a tomb in the Campo Santo. He had likewise a house of his own in Pisa, and houses and land in Florence. In recollection of life he is said to have been worthy of his first master, Fra Angelico.

The art of Gozzoli does not rival that of his greatest contemporaries either in elevation or in strength, but is pre-eminently attractive by its sense of what is rich, winning, lively, and abundant, in the aspects of men and things. His landscapes, thronged with birds and quadrupeds, especially dogs, more varied, circumstantial, and alluring than those of any predecessor, his compositions are crowded with figures, more characteristically true when happily and gracefully occupied than when the demands of the subject require tragic or dramatic intensity, or taint of action, his colour is bright, vivacious, and festive. Gozzoli's genius was, on the whole, more versatile and assimilative than vigorously original, his drawing not free from considerable imperfections, especially in the extremities and articulations, and in the perspective of his gorgeously-schemed buildings. In fresco-painting he used the methods of tempera, and the decay of his works has been severe in proportion. Of his unimpaired industry the rental of his labours, and the number of works produced, are the most forcible attestation.

GRAAT. See GRAY.

GRABE, JOHANN HENRICH (1666–1711), a learned divine of the Anglican Church, was born July 19, 1666, at Königsberg, where his father, the author of some treatises now forgotten, was professor of theology and law. In the course of his theological studies Grabe succeeded in persuading himself of the schismatical character of the Reformation of the 16th century, and accordingly presented to the consistory at Samland a memorial in which he compared the position of the evangelical Protestant churches with that of the Simonians, Novatians, and other ancient schismatics. Finally, however, he resolved to join the Church of Rome, when his peace was again disturbed by Spener and others, who had pointed out some flaws in his written argument, and called his attention to the English Church as apparently possessing that apostolic succession, and manifesting that fidelity to ancient institutions, which he desired. In 1697, accordingly, he removed to London, and received priest's orders, attaching himself to the non-juring party. The learned labours to which the remainder of his life was devoted were rewarded with an Oxford degree and a royal pension. He died on the 3d of November 1711, and in 1728 a monument was erected to him by Lord Oxford in Westminster Abbey.

Some account of Grabe's life is given by Dr. Thales in a discourse prefixed to the preface to Whiston's *Collection of Testimonies against the True Duty of the Son and of the Holy Ghost*. His works, which show him to have been a learned and industrious scholar, are in critical acumen, include a *Synopsis of the History of the Christian Church* (1698–99), which was designed to cover the first three centuries of the Christian church, but never was finished beyond the close of the second, editions of Justin's *Apology Prima* (1700), of Irenæus, *Adversus hæreses Hæreses* (1708), and of the Septuagint (*Vul. Test. græca LXX. univ. ed.*, 4 vols. fol., 1707–1750), also some polemical pieces now of little importance.

GRABOW, a town of Pomerania, Prussia, government district of Stettin and circle of Randow, is situated on the Oder below Stettin, and closely adjoining its suburbs Shipbuilding and the manufacture of machinery are the principal industries, and there is also a considerable ship-ping trade. Grabow did not acquire the rank of a town till 1855. The population in 1875 was 10,238.

GRACCHUS is the name of a family of the Gens Sempiterna. To this family there attaches a remarkably sweet and lovable nature, which, combined with their high character and ability, makes their history the most charming page in the Roman annals. Tiberius Sempiternus Gracchus was appointed master equitum after the battle of Cannæ, and held the consulship in 215 and 213 B.C. During the great weakness that followed the defeat at Cannæ the resolute and judicious generalship by which he easily seconded Fabius did much to maintain a courageous attitude at Rome. He raised some legions of slaves, and his generous conduct kept them together and made them important in the war. After several successes he was betrayed by a Lucanian into the hands of Mago, and having fallen in the battle that ensued, he was honoured with a magnificent burial by Hannibal. Another Tiberius, born about 210, married Cornelia, the daughter of Scipio Africanus, who is famous as the highest type of Roman matron. As pactor and propagator, Gracchus governed Hither Spain from 181 to 178. He conquered the Celtiberi, and by his magnanimous and kindly treatment of the Spaniards made a lasting impression on them. He was consul in 177 and 163. In 169, as censor, his review of the senate and equites was very strict, but though his colleagues became unpopular, Gracchus remained as much esteemed as ever. He enjoyed a high reputation for his power of calming down internal seditions and conciliating foreign enemies of the state. One of his daughters became the wife of Scipio Africanus the younger, while his two sons, Tiberius and Gnaeus, famous both for having determined the history of Rome at a critical point, are as re-

markable for the charm of their personal character and for the careful education given them by their widowed mother. Tiberius served as questor in Spain in 137; and the respect still entertained by the Spaniards for his father's name enabled him to save the Roman army from utter ruin after its defeat by the Numantines. See ROMAN HISTORY.

GRACES is the name generally given to the Greek goddesses Charites. The chief seat of their worship was the ancient Boeotian city Orchomenus. They were three in number, but their names were not known; and statues fallen from heaven stood in their temple as symbols of the goddesses (Paus., ix. 35). Their worship was instituted by a king Eteocles, whose three daughters fell into a well while dancing in honour of the Charites (Westermann, *Myth. Gr.*, p. 337). In no Greek legend is the pre-Greek Indo-Germanic character more strongly marked. Eteocles, he whose glory is real, is the Vedic Satyagruva, the sun; and his genealogy consists of a string of epithets for sun and dawn. Charis (Skt. *harī*, bright), is an old adjective, originally an epithet of the light-illuminated clouds which seem to escort the dawn, often applied in the Rig-Veda to the horses of the dawn or of the sun, and at last growing into a distinct deity who preserves the character of the ancient dawn-goddess (see Müller, *Lect. Lang.*, ii.; Sonne in Kalu, *Skt. Z.*). The burning bright waters (Ushas, *hū*, Aurora, with a different suffix *ōshas*, Easter) — who restores the blessings lost during the night, who lights up what was dark and reveals the hidden wrong, who gives active labour and wealth to men, growth and fertility to plants — had been from the earliest time the centre of a great worship. To appearance these religious ceremonies have been lost in Greece; and in a people so retentive of all that relates to religion, this implies merely that the worship of the dawn has been changed in outward form. Eos is of slight importance; but Charis, Hebe, Aphrodite (in so far as the genuine Greek goddess has not given way to the Oriental deity) preserve and develop the original idea. Charis then was the goddess of the freshness and vigour of life, of fertility and growth; like Aphrodite, she closely resembles Persephone (see Gerhardt, *Venus Proserpina*), and in later art the Graces often hold corn ears in their hands; like Hebe, she is often associated with Hera (see Welcker, *Gr. Göt.*, iii. 174). The single goddess grew into a triad, as occurs often in Greek mythology; in Sparta, however, and in Athens only two Charites were known. Rites of peculiar antique character belong to the worship of the Charites: in Orchomenus nightly dances took place in their honour (compare the legend of Eleusis's daughters, who obviously are byre forms of the goddesses); in Perse their worship was celebrated without music or garlands; in Messene they were worshipped along with the Eumenides; in Athens their rites secret from the vulgar were held at the entrance of the Acropolis; one swore by the Charites as one did by the deities of the lower world (Pollux, viii. 106). Far as these characteristics seem removed from the nature of a dawn-goddess we find a similar double character in many other cases, such as Artemis-Ecate. They are thus brought into the cycle of older more purely nature worship, which we find in Greece alongside of the more moral religion of the Olympian deities, and which has in mythology its counterpart in the older generation of Titans destroyed by the younger gods. The Charites were received into the Olympian Pantheon only in a subordinate character. In Homer we have a transitional stage; they appear sometimes as distinct independent beings, one being wife of Hephaestus, another of Sleep (*Il.*, xviii. 332, xiv. 231); often they are a set of nymphs attending on Aphrodite, herself then wife of Hephaestus (*Od.*, viii. 364, &c.). The dawn is naturally the wife of Hephaestus, the fire of the sun

in heaven and of the morning sacrifice on earth. In later literature this second form prevails. Obviously the noun *charis* and the connected verbs and substantives, which existed alongside of the mythological name, exercised a continually growing influence on it. The Charites become then the impersonation of the bloom of all sensuous appearance, of grace and cheerfulness, both in nature and in moral action. They form part of the train attendant on the greater gods, especially Aphrodite and Apollo. Their names, Aglaia, Euphrosyne, and Thalia, occur first in Hesiod (*Theog.*, 907). Pindar, however, following the Boeotian belief, celebrates them (*Ol.*, xiv.) as the queens of glittering Orchomenus and as the guardian-goddesses of the ancient Mynae. In art they were represented in earlier times as draped goddesses with varying attributes; gradually the one well-known conception predominated of the three beautiful nude figures gracefully intertwined. Jacobi (*Wörterb. d. Myth.*) gives a very complete list of ancient authorities.

GRACKLE (Latin, *Graculus* or *Graculus*), a word which has been much used in ornithology, but generally in a vague sense, though restricted to members of the families *Sturnida* belonging to the Old World, and *Icterida* belonging to the New. Of the former those to which it has been most commonly applied are the species variously known as Myiæ, Mainas, and Minors of India and the adjacent countries, and especially the *Gracula religiosa* of Linnaeus, who, according to Jerdon and others, was very properly led to confer this epithet upon it by confounding it with the *Sturnus* or *Aeridotheres tristis*,¹ which is regarded by the Hindus as sacred to Ram Deo, one of their deities, while

Gracula religiosa.

the true *Gracula religiosa* does not seem to be anywhere held in veneration. This last is about 10 inches in length, clothed in a plumage of glossy black, with purple and green reflexions, and a conspicuous patch of white on the quill-feathers of the wings. The bill is orange and the legs yellow, but the bird's most characteristic feature is afforded by the curious webles of bright yellow, which, beginning behind the eyes, run backwards in form of a lapet on each side, and then return in a narrow stripe to the top of the head. Beneath each eye also is a bare patch of the same colour. This species is common in southern India, and is represented further to the north, in Ceylon, Burmah, and some of the

¹ By some writers the birds of the genera *Aeridotheres* and *Tamias* are considered to be the true Myiæ, and the species of *Gracula* are called "Hill Myiæ" by way of distinction.

Malay Islands by egressive forms. They are all fringivorous, and, being easily tamed and learning to pronounce words very distinctly, are favourite cage birds.¹

In the New World the name *Grackles* has been applied to several species of the genera *Sceloporus* and *Quasius*, though these are more commonly called in the United States and Canada "Blackbirds," and some of them "Bont tails." They all belong to the family *Icthyidae*. The best known of these are the Rusty Grackle, *S. ferrugineus*, which pervades almost the whole of North America, and *Q. purpurus*, the Purple Grackle or Crow Blackbird, of more limited range, for though abundant enough in most parts to the east of the Rocky Mountains, it seems not to appear on the Pacific side. There is also Brewer's or the Blue-headed Grackle, *S. cyanocephalus*, which has a more western range, not extending to the eastward of Kansas and Minnesota. A fourth species, *Q. major*, is also found to inhabit the Atlantic States as far as North Carolina. All these birds are of exceedingly omnivorous habit, and though undoubtedly destroying large numbers of pernicious insects are in many places held in bad repute from the mischief they do to the corn crops. (A. N.)

GRACIÁN, BALTASAR (1681-1639), one of the principal "calistots" or Spanish prose writers of the school of Gongora, was born at Orlatayud, Aragón, in 1684. Little is known of his personal history except that on attaining to manhood he entered the Society of Jesus, and that ultimately he became superior of the Jesuit College at Tarragona, where he died in 1639. His principal works are *El Discurso* (1630), written in short compact sentences, which has been described as a sort of recipe for mixing a hero, *Los Agudices, y Arte del Ingenio* (1618), a sort of art of poetry or system of rhetoric in which the principles of "Gongorism" are inculcated, *Orticon* (1630-53), an allegory in which, under the imagery of the seasons of the year, the course of human life is described, *El Discurso*, a delineation of the typical character of a courtier, *Oráculo Menor*, a system of rules for the conduct of life. His works, which have been often reprinted in Spanish under the name of his brother Loucas, have also for the most part been translated into French and Italian. The *Oráculo Menor* has been translated into German by A. Schopenhauer (1832), and into English anonymously (*Courtier's Manual Oracle*, 1634). The *Heo* also occurs in English (from the French, 1726).

Gracian's merits as a writer have been very differently estimated by his critics, and it is probable that from none of them has he received strict justice. If his style is hardly so bombastic, involved, and obscure as his enemies represent it, neither can he in fairness receive all that credit for depth and originality of thought which is claimed for him by his friends. As examples of the widely differing appreciations which have been passed upon him, see Ticknor's *Spanish Literature*, vol. iii., and Mr Grant Duff's *Wanderer* (1878).

GRADISCA, a town of Austria, in the principality of Gorz and Gradisca, situated about 10 miles S W of Gorz, on the right bank of the Isonzo. It was formerly a strongly fortified place, but its citadel is now occupied as a prison. The inhabitants of the commune, who numbered in 1869 rather more than 3000, are engaged in silk spinning. Between 1471 and 1481 Gradisca was fortified by the Venetians, but in 1511 they surrendered it to the imperial forces. In 1617 Gradisca and its territory, including Aquileia and forty three smaller places, was erected into a prince-bishopric in favour of the prince of Eggenberg. It lapsed in 1717 to the imperial crown, and in 1754 was completely incorporated with Gorz. The name was revived by the constitution of 1861, which established the crown-land of the county of Gorz and Gradisca. See Gorz.

GRADUATION is the name given to the art of dividing straight scales, circular arcs, or whole circumferences into any required number of equal parts. It is the most important and difficult part of the work of the mathematical instrument maker, and is required in the construction of most physical, astronomical, nautical, and surveying instruments, such as thermometers, scales, linear measuring instruments, quadrants, sextants, mural circles, theodolites, &c.

The art was, undoubtedly, first practised by clockmakers for cutting the teeth of their wheels at regular intervals, but so long as it was confined to them, no particular delicacy or accurate nicety in its performance was required. This only arose when astronomy began to be seriously studied, and the exact position of the heavenly bodies to be determined, which created the necessity for strictly accurate means of measuring linear and angular magnitude. Then graduation began to be looked upon as an art which required special talents and training, and hence we find that all the best artists have spent their best efforts on the perfecting of astronomical instruments. Of these may be named Abraham Sharp, Bird, Smeaton, Ramsden, the Duc de Chaulnes, John and Edward Troughton, Sumner, and Ross.

It is obvious that the first graduated instrument must have been done by the hand and eye alone, whether it was in the form of a straight edge with equal divisions, or a screw, or a divided plate, but, once in the possession of one such divided instrument, it was a comparatively easy matter to employ it as a standard, and copy its divisions on any other article that might be desired. Hence graduation naturally divides itself into two distinct branches, *original graduation* and *copying*, which latter may be done either by the hand or by a machine called a dividing engine. We may thus speak of graduation under the three heads of *original graduation*, *copying*, and *machine graduation*.

Original graduation.—This is by far the most difficult part of the art—so difficult, indeed, and requiring such accuracy of hand and eye, that but few in any generation have been completely competent for the task. The earlier astronomers graduated their own instruments, and, from the examples that have come down to us, it must have been very roughly done as compared with modern work.

In regard to the graduation of straight scales, we have, by elementary geometry, the means, theoretically, of dividing a straight line into any number of equal parts, but the practical carrying out of the geometrical construction is beset with difficulties as to render the method unusable. This method, which employs the common diagonal scale, was used in dividing a quadrant of 3 feet radius, which belonged to Neper of Merchiston, and which only read to minutes—a result, say Thomson and Tait (*Nat. Phil.*), "giving no greater accuracy than is now attainable by the pocket sextants of Troughton and Sumner, the radius of whose arcs is little more than an inch."

The original graduation of a straight line is, in practice, done either by the method of continual bisection or by stepping. In continual bisection the entire length of the line is first laid down. Then, as neatly as possible, half that distance is taken in the beam compass and marked off by faint arcs from each end of the line. Should these marks coincide the exact middle point of the line is obtained. If not, as will almost always be the case, the distance between the marks is carefully bisected by hand with the aid of a magnifying glass. The same process is again applied to the halves thus obtained, and so on in succession, dividing the line into parts represented by 2, 4, 8, 16, &c., till the desired divisions are reached. In the method of stepping the smallest division required is first taken, as accurately as possible, by using dividers, and that distance is then laid off, by successive steps, from one end of the line. It is evident that, in this method, any error at starting will be

¹ For a valuable monograph on the various species of *Grackles* and its allies, see Prof Schlegel's *Revue des Grackles ou des Grackes* (Nederlandsche Tijdschrift voor de Dierkunde, 1871, pp. 1-9).

multipled at each division by the number of that division. Errors so made are usually adjusted by the dots being put either back or forward a little by means of the dividing patch glass, by a magnifying glass. This is an extremely tedious process, and the dots when so altered several times, are apt to get irretrievably large and shapeless.

The division of circular arcs is essentially the same in principle as the graduation of straight lines, and of this we shall now give some examples.

The first example of note is the 8-foot mural circle which was graduated by Graham for the National Observatory in 1725. In this two consecutive arcs, of 100' 56' 56" and 65' 3" inches respectively were first divided by the beam compass. On the inner of these the arc of 60° was to be divided into degrees and 12th parts of a degree, while the sum of the outer arc was to be divided into 90 equal parts, and these again into 16th parts. The reason for adopting the latter was that, 90 and 16 being both powers of 2, the divisions could be got at by continual bisection alone, which, in Graham's opinion, was first employed in this, the only accurate method of dividing the circle arc. With the same distance on the beam compass a was used to describe the inner arc, laid off from 0°, the point 60° was at once divided into 12 equal parts.

With the points 0° and 60° as centres, successively, and a distance on the beam compass very neatly bearing the arc of 60°, two slight marks were made on the arc, the distance between these marks was exactly divided by the beam compass by a line drawn from the point 0° to the point of 60° laid off from the point 30° gave the point 60°, and the quadrant was now divided into three equal parts. Each of these parts was mutually bisected, and the resulting divisions were again bisected, giving 18 parts of 7' each. At the same time the outer arc was divided, the 12th part of which was arrived at by bisection and 1/2 bisection as before. The outer arc was divided by continual bisection alone, and a table was constructed by which the readings of the one arc could be compared with those of the other. After the dots making the required divisions were obtained, other slight strokes all divided down to the centre were drawn through them by the dividing knife, or some other small tool was drawn through them by the beam compass having its steel point somewhere on the line which was a tangent to the quadrant arc at the point where a division was to be marked.

The next important example of graduation was done by Burt in 1767. His quadrant, which was 8 feet radius, was divided into degrees and 12th parts of a degree. He employed the method of continual bisection aided by the chords taken from an exact scale of equal parts, which could be set to 901 of its radius, and which he had previously graduated by continual bisection. With the beam compass in arc of radius 81 983 inches was first drawn. From this radius the chords of 30°, 15°, 30°, 20°, 45°, 40°, and 42° 40' were compared, and each of them by means of the scale of equal parts laid off on a separate beam compass to be ready. The radius laid off from 0° gave the point 60°, by the chord of 30° the arc of 60° was bisected, from the point 30° the chord of 40° gave the point 75°, the chord of 15° laid off from the point 60° gave the point 75°, from 75° was laid off forwards the chord of 10° 20', and from 90° was laid off backwards the chord of 5° 40', and these were found to coincide in the point 85°. Now 85° 30' = 102 1/2° × 80', the final division of 85° 30' was found by continual bisection. For the remainder of the quadrant beyond 85° 30', containing 58 divisions of 6' each, the chord of 64 such divisions was laid off from the point 85° 30', and the point depending on it divided by continual bisection as before. This was thus a screw chain upon the accuracy of the points already found, viz., 15°, 30°, 60°, 75°, 90°, which, however, were found to coincide with the corresponding points obtained by bisection. The same method was followed in the dots were drawn in the way already mentioned.

The next important atlas in original graduation was the Mother's John and Edward Troughton. The former was the first to devise a new way of graduation, and was employed by continual bisection without the aid of such a scale of equal parts as was used by Burt. His method was as follows:—The radius of the quadrant laid off from 0° gave the point 60°. This arc bisected and the half laid off from 60° gave the point 90°. The arc between 60° and 90° bisected gave 75°, the arc between 75° and 90° bisected gave the point 82° 30', and the arc between 82° 30' and 90° bisected gave the point 85° 15'. Further, the arc between 82° 30' and 85° 15' bisected, and two thirds of it taken beyond 82° 30' gave the point 85°, while the arc between 85° and 85° 15' also bisected, and one third part laid off beyond 85°, gave the point 85° 25'. Lastly, the arc between 85° and 85° 25' being unquadrated, and four fifths taken beyond 85°, gave 85° 20', while the arc $n = 8^\circ \times 2\frac{1}{2}$, and so can be finally divided by continual bisection.

Edmund Troughton's Method.—The method of original graduation discovered by Edmund Troughton is fully described in the *Philosophical Transactions* in 1809, as employed by himself to divide a

mural circle of 1 foot radius. The circle was first accurately turned both on its face and its inner and outer edges. A roller was next provided, of such diameter that it revolved 16 times on its own axis while made to roll once round the circle, and the circle. This roller, made most like an ivory, was divided into a frame work, which could be slid freely, or tightly, along the circle, the roller meanwhile revolving, by means of friction it carried, on the outer edge. The roller was also, after having been properly adjusted as to size, divided so accurately it was possible into 26 equal parts by lines parallel to its axis. While the frame carrying the roller was moved once round along the circle, the points of contact of the roller's divisions with the circle were accurately observed by two microscopes attached to the frame, one of which (which we will call H) communicated the ting on the circle near its edge, while the other was also, after having been properly adjusted, divided into 26 equal parts by lines parallel to its axis. The next part of the operation was to find and tabulate the errors of these dots, which are called *apparent errors*, in consequence of the error of each dot being sustained on the supposition of its neighbouring being all correct. For this purpose two microscopes (which we will call A and B) were fixed, with cross wires and micrometer adjustments, consisting of a screw and lead divided into 100 divisions, 50 of which read in the one and 50 in the opposite direction. These microscopes, A and B, were fixed so that their cross-wires were exactly bisected by the dots 0 and 128, which were supposed to be diametrically opposite. The circle was now turned back to its point on its axis, so that dot 128 coincided with the wire of A, and should dot 0 be found to coincide with the wire of B, the dots were set to the wire of A, and the wire of B was of B was now shifted, A then being opposite dot 0 as before, till its wire bisected dot 64, and by giving the circle one quarter of a turn on its axis, the distance of the wire of B from dot 0 and between 64 and 128 was obtained. The half of this difference gave the apparent error of dot 64, which was tabulated with its proper sign. With the microscopes A and B in the same position the error of dot 128 was obtained, and in the same way by sliding it to dot 32 the errors of dots 32, 96, 160, and 224 were successively ascertained. By proceeding in this way the apparent errors of all the 256 dots were tabulated.

From this table of apparent errors a table of real errors is obtained by employing the following formula:—
$$\frac{1}{2}(a + i) + i = \text{the real error of dot } i,$$
 where a is the real error of dot a , i the real error of dot i , and the apparent error of dot i midway between a and i . Thus having got the real error of any two dots, the table of apparent errors gives the means of finding the real error of all the other dots. The above formula is easily derived as follows:—Let a and i be the number of points (or divisions) from 0 to dots a and i respectively, and let i be the number of divisions from a to the point i supposed to be midway between a and i . Also let a and i be the real errors of dots a and i , and the apparent error of i . Then we have

$$-b = a - i - \frac{1}{2}(a - i) - b = \frac{1}{2}(a + i)$$

Now the real positions of a and i are $a - a$, and $i - i$, respectively. Therefore the real position of b , the point midway between a and i , is

$$-a - i - \frac{1}{2}(a - i) - (a - i) = -2(a + i) - \frac{1}{2}(a - i)$$

Therefore the real error of b

$$-b = -2(a + i) - \frac{1}{2}(a - i) - \frac{1}{2}(a - i)$$

Having obtained the 256 dots and their real errors, the third and last part of Troughton's process was to employ them to cut the final divisions of the circle, which were to be equal to 5' each.

Now the mean interval between any two dots is $\frac{360^\circ}{256} = 1^\circ 16'$, and hence, in the final division, this interval must be divided into 16 equal parts. In order to accomplish this a small instrument, called a subdividing sector, was provided. It was made of thin brass and had a radius about four times that of the roller, but made adjustable as to length. The sector was placed concentrically on the circle, and rested on the upper edge of the roller. It turned by frictional adhesion along with the roller, but at the same time was sufficiently loose to allow of its being moved back to any position without affecting the roller. Now it is evident that, while the roller moves on an angular space equal to the mean interval

between two dots, any point of the sector must pass over 18 times that interval, that is to say, over an angle represented by $850 \times 16 = 22' 30''$. This interval was therefore divided by 18, and 355

a space equal to 16 of the parts thence. This was laid off on the arc of the sector and gradually divided into 16 equal parts, each equal to $1' 20''$, and, in order to provide for the necessity of a division, that was laid off at each end of the sector, and beyond the 16 equal parts, two of these parts each subdivided into 8 equal parts. A microscope with cross wires, which we shall call *I*, is placed on the main frame, so as to command a view of the sector divisions, just as the microscope *II* viewed the final divisions of the circle. Before the first or *zero* mark was cut, the zero of the sector was brought under *I*, and then the divider cut at the point on the circle indicated by *II*, which also coincided with the dot 0. The frame was then slipped along the circle by the slow screw motion provided for the purpose, till the first sector division, by the action of the tolls, was brought under *I*. The second mark was then cut on the circle at the point indicated by *II*. When the marks thus obtained are brought up, it they should be, is evident what we reflect that the distance between them must be each of a division on the sector which by construction is $1' 20''$. By proceeding in this way the first 16 divisions were cut, but before cutting the 17th it was necessary to adjust the micrometer wires of *H* to the real circle of dot 1, as indicated by the table, and bring back the sector, not to zero, but to 4th part of zero. Striding from this position the divisions between dots 1 and 2 were next filled in, and then *H* was adjusted to the 1st error of dot 2, and the sector brought back to its proper division before commencing the third course. By proceeding in this manner through the whole circle, the microscope *H* was finally found with its wire at zero, and the sector with its 16th division under *I*, a microscope indicating that the circle had been accurately divided.

Copying.—In graduation by copying the first requisite is a pattern, which must be either an accurately divided straight scale, or an accurately divided circle, commonly called a *dividing plate*.

In copying a straight scale the pattern and scale to be divided, usually called the work, are first fixed side by side, with their upper faces in the same plane. The dividing square, which closely resembles an ordinary joiner's square, is then laid across both, and the point of the dividing knife dropped into the zero division of the pattern. The square is now moved up close to the point of the knife, and, while it is held firmly in this position by the left hand, the first division on the work is made by drawing the knife along the edge of the square with the right hand. Great care must be taken that the knife is held exactly in the same position in cutting the division and in setting the square.

It frequently happens that the divisions required on a scale are either greater or less than those on the pattern. To meet this case, and still use the same pattern, the work must be fixed at a certain angle of inclination with the pattern. This angle is easily found in the following way. Take the exact ratio of a division on the pattern to the required division on the scale. Call this ratio *a*. Then, if the required divisions are longer than those of the pattern, the angle is $\cos^{-1}a$, but, if shorter, the angle is $\sec^{-1}a$. In the former case two operations are required before the divisions are cut: first, the square is laid on the pattern, and the corresponding divisions merely notched very faintly on the edge of the work, and, secondly, the square is applied to the work and the final divisions drawn opposite each faint notch. In the second case, that is, when the angle is $\sec^{-1}a$, the dividing square is applied to the work, and the divisions cut when the edge of the square coincides with the end of each division on the pattern.

In copying circles use is made of the dividing plate. This is a circular plate of brass, of 36 inches or more in diameter, carefully graduated near its outer edge. It is turned quite flat, and has a steel pin fixed exactly in its centre, and at right angles to its plane. For guiding the dividing knife an instrument called an *index* is employed. This consists of a straight bar of thin steel of length equal to the radius of the plate. A piece of metal, having a \vee notch with its angle a right angle, is riveted to one end of the bar

in such a position that the vertex of the notch is exactly in a line with the edge of the steel bar. In this way, when the index is laid on the plate, with the notch grasping the central pin, the straight edge of the steel bar lies exactly along a radius. The work to be graduated is laid flat on the dividing plate, and fixed by two clamps in a position exactly concentric with it. The index is now laid on, with its edge coinciding with any required division on the dividing plate, and the corresponding division on the work is cut by drawing the dividing knife along the straight edge of the index.

Machine Graduation.—The first dividing engine was probably that of Henry Hindley of York, constructed in 1740, and used for the most part by him for cutting the teeth of clock wheels. This was followed shortly after by an engine devised by the Duc de Chaulnes, but the first engine which obtained distinct notoriety was that made by Ramsden, of which an account was published by the Board of Longitude in 1777. He was rewarded by that board with a sum of £300, and a further sum of £315 was given to him on condition that he would divide, at a certain fixed rate, the instruments of other makers. The essential principles of Ramsden's machine have been repeated in almost all succeeding engines for dividing circles, and it will be well, therefore, to give a brief description of it.

It consisted of a large brass plate 45 inches in diameter, and equally movable on a vertical axis. The edge of this plate was studded with 2160 teeth, into which a tangent screw worked, by means of which the plate could be made to turn through any required angle. Thus at turns of the screw moved the plate through $1'$, and $\frac{1}{16}$ th of a turn through $\frac{1}{16}$ th of a degree. On the axis of the tangent screw was placed a cylinder having a spiral groove cut on its surface. Aatchet wheel containing 60 teeth was attached to this cylinder, and was so arranged that, when the cylinder moved in one direction, it caused the tangent screw to revolve, and so turned the plate, but when it moved in the opposite direction, it left the tangent screw, and with it the plate, stationary. Round the spiral groove of the cylinder a cord ran as a wheel, one end of which was attached to a treadle on the other to a counterpoise weight. When the treadle was depressed the tangent screw turned round, and when the pressure was removed it returned, in obedience to the weight, to its former position without affecting the screw. Provision was also made whereby certain stops could be placed in the way of the screw, which only allowed it the requisite amount of turning according to the graduation required. The work to be divided was firmly fixed on the plate, and made concentric with it. The divisions were cut, while the screw was stationary, by means of a dividing knife attached to a wing frame, which allowed it to have only a radial motion. In this way the circle could divide very rapidly by alternately depressing the treadle and working the dividing knife.

Ramsden also constructed a linear dividing engine on essentially the same principle. If we imagine the rim of the circular plate with its notches stretched out into a straight line and made movable in a straight slot, the screw, treadle, &c., remaining as before, we shall get a very good idea of the linear engine.

In 1793 Edward Troughton finished a circular dividing engine, of which the plate was smaller than in Ramsden's, and which differed considerably both in simplifying matters of detail. The plate was originally divided by Troughton's own ingenious method, already described, and the divisions so obtained were employed to match the edge of the plate for receiving the tangent screw with great accuracy.

In the *Transactions of the Society of Arts* for 1830-31 there is a full description, with illustrative figures, of a dividing engine, constructed by Andrew Ross, which differs considerably from those of Ramsden and Troughton.

The essential point of difference is that, in Ross's engine, the tangent screw does not turn the engine plate, that is done by an independent apparatus, and the function of the tangent screw is to move the plate after it is moved through the required angular interval between two divisions on the work to be graduated. Round the circumference of the plate are fixed 48 projections which just look as if the circumference had been divided into 48 equal parts, somewhat peculiarly shaped, resembling \vee 's. Through each of these teeth a hole is bored parallel to the plane of the plate

SYRACUSE. Mutual discord first sapped the prosperity of Magna Græcia. In 510 Crotone, having defeated the Sybarites in a great battle, totally destroyed their city. Crotone maintained alone the leading position which had belonged jointly to the Achaean cities (Diod. xiv 103), but from that time Magna Græcia steadily declined. Foreign enemies pressed heavily on it. The Lucanians and Brutians on the north captured one town after another. Dionysius of Syracuse attacked them from the south, and after he defeated the Crotonean league (389 B.C.), Tarentum remained the only powerful city. Henceforth the history of Magna Græcia is only a record of the vicissitudes of Tarentum (see TARENTUM). Repeated expeditions from Sparta and Epizus tried in vain to prop up the decaying Greek states against the Lucanians and Brutians, and when in 323 the Romans appeared in the Tarentine Gulf the end was close at hand. The aid which Pyrrhus brought did little good to the Tarentines, and his final departure in 274 left them defenceless. During these constant wars the Greek cities had been steadily decaying, and in the second Punic war, when most of them seized the opportunity of revolting from Rome, their very existence was in some cases annihilated. Malacia, which never affects a well peopled city, increased in strength as the population diminished. We are told by Cicero (*De leg. 4*), "Magna Græcia nunc quædam deserta est." Many of the cities completely disappeared, and, like Tarentum, maintained a feeble existence in later times.

GREVIUS (1632-1703) Johann Georg Grevio, or Grevius, one of the great classical scholars of the 17th century, was born at Naumburg, Saxony, 29th January 1632, and after receiving the usual school education at the gymnasium of Pforta became a student of law in the university of Leipzig. During a casual visit to Deventer in his eighteenth year, he became acquainted with Gronovius, and this circumstance greatly stimulated a taste for pure scholarship which he had already begun to display somewhat to the detriment of his professional prospects. Finally abandoning jurisprudence shortly afterwards, he studied philology for two years under Gronovius, and subsequently sat under Heurnius at Leyden, and under Moëtus and Bioriel at Amsterdam. During his residence in the last-named city he abandoned Lutheranism and joined the Reformed Church, and in 1656 he was called by the elector of Brandenburg to the chair of belles lettres in the university of Duisburg. Two years afterwards he was, on the recommendation of Gronovius, chosen to succeed that scholar at Deventer, and in 1662 he was translated to the university of Utrecht, where he occupied first the chair of rhetoric, and afterwards from 1667 until his death (January 11, 1703) that of history and politics. During the later years of his life he enjoyed a great European reputation, and repeated attempts, which, however, he steadfastly resisted, were made to induce him to transfer his services to other universities and Governments. His lecture-room was crowded by pupils, many of them of distinguished rank, from all parts of the civilized world, and by Louis XIV., as well as by other sovereigns, he was now and again honoured with special recognition.

Of his works the two most important are the *Thesaurus Antiquitatum Romanarum*, published in 12 volumes at Utrecht (1694-1698), and the *Thesaurus Antiquitatum et Historiarum Rerum*, published after his death, and continued by Buermann (1704-1726). His editions of the classics, although at the time of their appearance they marked a distinct advance in scholarship, are now for the most part superseded. They include *Horatii Aratorum quæ ævum* (1667), *Lucretii Pharsaliæ* (1668), *Julianæ Saturnæ Philoponæ* (1668), *Suetonii* (1672), *Catullus, Tibullus, et Propertius* (1680), and several of the works of Cicero. *The Oratio Funeris* by F. Buermann (Utrecht, 1708) contains an exhaustive list of the works of this scholar.

GRAFE, ALBRECHT VON (1828-1870), German oculist, son of Karl Ferdinand von Grafe, noticed below, was born at Berlin in May 1828. At an early age he manifested a preference for the study of mathematics, but this was gradually superseded by an interest in natural science, which led him ultimately to the study of medicine. After obtaining Government licence at Berlin, he prosecuted his studies at Vienna, Prague, and Paris, devoting special attention to ophthalmology. In 1850 he began practice as an oculist in Berlin, where he founded a private institution for the treatment of the eyes, which became the model of many similar ones in Germany and Switzerland. In 1853 he was appointed teacher of ophthalmology in Berlin university, in 1856 extraordinary professor, and in 1866 ordinary professor. Von Grafe contributed largely to the perfection of the science of ophthalmology, especially by the establishment in 1855 of his *Archiv für Ophthalmologie*, in which he had Alt and Donders as collaborators. Perhaps his two most important discoveries are his method of treatment for *glaucoma*, until then deemed incurable, and his new method of operation for the extraction of cataract, by which the danger of the operation became minimized. He was also regarded as an authority in diseases of the nose and brain. He died at Berlin 20th August 1870. See Alford Grafe, *Ein Wort zur Erinnerung an Albrecht von Grafe*, Halle, 1870.

GRAFE, FERDINAND (1602-1668), educationist, was born at Buttsstadt in Werra, 3d May 1609, studied mathematics and theology at Jena, and in 1623 obtained a curacy in the Stadtkirche of Weimar. Thence he was transferred to Jena as rector of the town school in 1625, in 1640 he was also appointed extraordinary professor of the science of education (Pädagogik) at that university, and in 1642 he became head of the Bürgerschule in Cassel. After resigning the schools of the town, he became director of the new realische in 1643, and, devoting himself with great zeal and energy to the interests of educational reform in electoral Hesse, he became in 1649 a member of the school commission, and also entered the house of representatives, where he attached himself to the democratic party and made himself somewhat formidable as an agitator. In 1652 for having been implicated in the September riots and in the movement against the unpopular minister Hassenpflug (who had dissolved the school commission) he was condemned to three years' imprisonment, a sentence which was afterwards reduced to one of twelve months. On his release he withdrew to Geneva, where he engaged in educational work till 1655, when he was appointed director of the school of industry at Bremen. He died in that city 21st July 1668.

Besides being the author of many text books and occasional papers on educational subjects, he wrote *Der Buchhalter in der Volksschule vom ersten u. ausserm (1629)*, *Die Schulförderung (1631)*, *Schule u. Unterricht (1638)*, *Allgemeine Pädagogik (1645)*, *Die Deutsche Volksschule (1647)*. Along with Neumann, he edited the *Archiv für das praktische Volksschulwesen (1828-35)*.

GRAFE, KARL FERDINAND VON (1787-1840), German surgeon, was born at Walsaw, 8th March 1787. He studied medicine at Halle and Leipzig, and after obtaining licence from the latter university, he was in 1807 appointed private physician to Duke Aloisius of Anhalt-Bernburg. In 1811 he became professor of surgery at Berlin, and during the war with Napoleon he was superintendent of the military hospitals. When peace was concluded in 1815, he resumed his professional duties. He was also appointed to the medical staff of the army, and he became a director of the Frederick-Wilhelm Institute, and of the Prussian-Chirurgical Academy. He died suddenly, 4th July 1840, at Hanover, whither he had been called to operate on the eyes of the crown-prince. Von Grafe did much to advance the practice of surgery in Germany, especially in the case of wounds, both by the invention of new instruments and the discovery

of new methods of treatment. He improved the rhinoplastic process, and his revival was chiefly due to him. His lectures at the university of Berlin attracted students from all parts of Europe.

The following are his principal works:—*Abhandlung über die Atmungsgewebe* (Gießen, Berlin, 1812, *Abhandlung*, 1818, *Neue Beiträge zur Kenntniss des Atmungsorgans* u. s. w., 1820, *Die epulische Leugung*, *Angewandte Anatomie*, *Abhandlung über die Atmungsgewebe* (Zürich, 1824), *Festschrift der Universität zu Berlin*, 1817-34. He also edited, along with Ph. von Walther, the *Journal für Chirurgie und Augenheilkunde*.

GRAFRATH, a town of Rhine-Prussia, government district of Düsseldorf, circle of Solingen, situated on the small river Itter, 14 miles E. of Düsseldorf. It has iron foundries, and manufactures of steel wares, chemical, cotton, and silbons. The population in 1875 was 5604.

GRAGNANO, a town of Italy, in the province of Naples and circle of Castellamare, about 2½ miles E. of Castellamare. It is the seat of a bishop and has a collegiate church, manufactures, cloth and macaroni, and exports an excellent red wine which is well known at Naples. In earlier times it was surrounded with walls and defended by a castle. Population (1871) of town 7221, of commune 12,378.

GRAHAM, SIR JAMES GEORGE ROBERT, Bart. (1792-1861), a well-known British statesman, was born at Naworth, Cumberland, 1st June 1792. From Westminster school he duly passed to Queen's College, Cambridge, and shortly after quitting the university, while making the "grand tour" abroad, he became private secretary to the British minister in Sicily, in which capacity he not only acquired much useful experience but also rendered some important services. Shortly after his return to England he, in 1818, after a contest of extraordinary keenness, was returned to parliament as member for Hull in the Whig interest, but he was unseated at the election of 1820. In 1824 he succeeded to the baronetcy on his father's death, and in 1826 he again entered parliament as representative for Carlisle. In the same year he published a pamphlet entitled *Coin and Currency*, which brought him into considerable prominence in the political world as a man of advanced Liberal opinions, and having been returned in 1830 for the county of Cumberland, he became one of the most energetic advocates in parliament of the Reform Bill. On the formation of Earl Grey's administration he received the post of first lord of the admiralty, with a seat in the cabinet. From 1832 to 1837 he sat for the eastern division of the county of Cumberland, but discussions on the Irish Church question led to his withdrawal from the ministry in 1834, and ultimately to his joining the Conservative party. Rejected by his former constituents in 1837, he was in 1838 elected for Penrith, and in 1841 for Dorchester. In the latter year he took office under Sir Robert Peel as secretary of state for the home department, and this post he retained until 1846. As home secretary he incurred considerable odium, in Scotland at least, by his unconciliating policy on the church question prior to the "disruption" of 1843, and in 1844 the denunciation and opening of letters at the post office by his warrant raised a storm of public indignation, which was hardly allayed by the favourable report of a parliamentary committee of investigation. From 1846 to 1852 he was out of office, but in the latter year he joined Lord Aberdeen's cabinet as first lord of the admiralty, in which capacity he acted also for a short time in the Palmerston ministry of 1855, until the appointment of a select committee of inquiry into the conduct of the Russian war put him upon his defence, and ultimately led to his withdrawal from official life. He continued, however, as a private member to exercise a considerable influence on parliamentary opinion until his death, which occurred at Netherby, Cumberland, 26th October 1861.

GRAHAM, THOMAS (1804-1869), born at Glasgow, on the 21st of December 1804, was the son of a merchant of that city. In 1819 he entered the university of Glasgow, and graduated in 1824. At this time the chair of chemistry was held by Dr Thomas Thomson, whose researches bearing on the atomic theory cannot fail to have had much influence in turning Graham's thoughts to the study of molecular physics to which he so patiently devoted his life. The beginning of his career appears to have been much embittered by his father's opposition, who wished him to become a minister of the Established Church. His own views, however, prevailed, and he worked for two years in the laboratory of Dr Hope of Edinburgh before returning to Glasgow, where he taught mathematics, and subsequently chemistry, until the year 1829, when he was appointed lecturer in the Mechanics Institution. In 1830 he succeeded Dr Ure as professor of chemistry in the Andersonian Institution, and, on the death of Dr Edward Turner, he was transferred to the chair of chemistry in University College, London. He presided over the chemical section of the British Association at the Birmingham meeting in 1839, and in 1841 was chosen as the first president of the Chemical Society of London. He resigned his professorship on being appointed to succeed Sir John Herschel as Master of the Mint, a post he held until his death in September 1869. This appointment was doubtless offered to him for its eminent recognition of his scientific services, but the onerous duties of the important office severely tried his energies, and it is unfortunate that, in quitting a purely scientific career, he should have been subjected to the care of official life for which he was by temperament singularly unfit. The researches, however, which he conducted between 1831 and 1860 were as brilliant as any of those in which he engaged. Graham was elected a fellow of the Royal Society in 1837, a corresponding member of the Institute of France in 1847, and doctor of civil law in 1855. The presidency of the Royal Society was offered him towards the close of his life, but his failing health caused him to shrink from accepting the honour.

The persistency with which he traced and developed the laws of atomic motion was remarkable. It is interesting therefore to remember that his future work must have been indicated in no small measure by the researches of the illustrious Black, who, at the beginning of the century, rejected the definitions of chemistry proposed by Stahl, Boethaave, and Fourcroy, and lectured "on the strict produced by heat and mixture in all bodies or mixtures of bodies natural or artificial" (Graham communicated papers to the Philosophical Society of Glasgow before the work of that society was recorded in *Transactions*, but his first published paper, "On the Absorption of Gases by Liquids," appeared in the *Annals of Philosophy* for 1826, and is of special interest, as in it he speaks of the liquefaction of gases in much the same terms as those employed in the last paper he wrote. The subject with which his name will always be most prominently associated is the molecular mobility of gases. This he observed in 1799 that hydrogen passed from a coloured glass jar in exchange for external air which "had nothing inflammable in it," and Dalton proved in 1806 that gases confined in glass vessels, connected by glass tubes, intermix even against the action of gravity (Graham in his first paper on this subject (1833) thus summarizes the known experiment had alluded as to the laws which regulate the movement of gases: "Excluding the mobility of gases has been in interesting speculations, the extensive information we possess on the subject amounts to little more than the well-established fact that gases of a different nature, when brought into contact, do not arrange themselves according to their density, but they spontaneously diffuse

through each other so as to remain in an intimate state of mixture for any length of time." For the fissured jar of Priestley and Dubouché he substituted a glass tube closed by a plug of plaster of Paris, and with this simple appliance he developed his now well-known law "that the diffusion rate of gases is inversely as the square root of their density."

With regard to the special importance of Graham's law to the chemist and physicist, it may be sufficient to point out that a great number of chemical as well as physical facts are co-ordinated by the assumption that all substances in the state of gas have the same molecular volume or contain the same number of molecules in a given space (Avogadro's law), and, in the second place, it has become evident that the phenomena of heat are simply the manifestations of molecular motion. According to this view the absolute temperature of a gas is proportional to the *vis viva* of its molecules, and since all molecules at a given temperature have the same *vis viva*, it follows that the molecules must move with velocities which are inversely proportional to the square roots of the molecular weights. Moreover, since the molecular volumes are equal, and the molecular weights are therefore proportional to the densities of the gaseous bodies in which the molecules are active units, it also follows that the average velocities of the molecules in any two gases are inversely proportional to the square roots of their respective densities. Thus the simple numerical relations first observed in the phenomena of diffusion are the direct result of molecular motion, and it is now seen that Graham's empirical law is included under the fundamental law of motion.

Graham also studied the passage of gases by transpiration through fine tubes, and by effusion through a minute hole in a platinum disc, and was enabled to show that gas may enter a vacuum in three different ways. (1) by the molecular movement of diffusion, in virtue of which a gas penetrates through the pores of a disc of compressed graphite, (2) by effusion through an orifice of sensible dimensions in a platinum disc (the relative times of the effusion of gases in mass being similar to those of the molecular diffusion, although a gas is usually carried by the former kind of impulse with a velocity many thousand times as great as is demonstrable by the latter), and (3) by the peculiar rate of passage due to transpiration through fine tubes, in which the ratios appear to be in direct relation with no other known property of the same gases—thus hydrogen has exactly double the transpiration rate of nitrogen, the relation of these gases as to density being as 1 : 14.

He subsequently examined the passage of gases through septa or partitions of india-rubber, and plates of non-crystalline metals such as palladium, and proved that gases pass through these septa neither by diffusion, effusion, nor transpiration, but in virtue of a selective absorption which the septa appear to exert on the gases in contact with them. By this means he was enabled partially to separate oxygen from air, and to calculate the density of metallic hydrogen from the remarkable expansion which attends the absorption of hydrogen by palladium. The experiments led him to believe that palladium with its occluded hydrogen was an alloy, a view that has been greatly strengthened by the recent experiments of MM. Cailliet and Pieter.

His early work on the movements of gases led him to examine the spontaneous movements of liquids, and as a result of the experiments he divided bodies into two classes,—crystalloids, such as common salt, and colloids, of which gum-arabic is a type,—the former having high and the latter low diffusibility. He also proved, by a series of beautiful experiments that the process of liquid diffusion actually causes partial decomposition of certain chemical compounds, the sulphate of potash, for instance,

being separated from the sulphate of alumina in alum by the higher diffusibility of the former salt.

He also extended his work on the transpiration of gases to liquids, adopting the method of manipulation devised by Fosseville. He found that dilution with water does not effect proportionate alteration in the transpiration velocities of different liquids, and a certain determinable degree of dilution retards the transpiration velocity. Thus in the case of alcohol the greatest retardation is with six equivalents of water, nitric acid with three, and acetone with as much as twelve equivalents.

It is only possible here to indicate the prominent features of Graham's more purely chemical labours. In 1833 he showed that the various compounds of phosphoric acid and water constitute distinct salts, in each of which the hydrogen may be displaced by other metals. It was the first, therefore, to establish the existence of polybasic compounds, in each of which one or more equivalents of hydrogen are replaceable by certain metals, and he further showed that by heating biphosphate of soda a metaphosphate is formed, and from this he obtained a corresponding hydrated acid. In 1824 he demonstrated that the spontaneous inflammability of one variety of phosphuretted hydrogen is due to its admixture with a very small proportion of an oxide of nitrogen, probably nitrous acid. In 1835 he published the results of an examination of the properties of water as a constituent of salts. Not the least interesting part of this inquiry was the discovery of certain definite salts with alcohol analogous to hydrates, to which the name of alcoholates was given. A brief paper entitled *Speculative Views on the Constitution of Matter* deserves notice as possessing special interest in connexion with work done since Graham's death. In it he expressed the view that the various kinds of matter now recognised as different elementary substances may possess one and the same ultimate or atomic molecule in different conditions of movement.

Graham's work, viewed as a whole, is remarkable alike for its originality and for the singular simplicity of the methods employed in obtaining most important results.

Biographical notices of Graham will be found in the *Proceedings of the Royal Society*, xvii, 1876, p. cviii; *Proceedings of the Royal Society of Edinburgh*, vii, 1878, p. 16; *Proceedings of the Royal Institution*, vi, 1873, p. 15; *Deutsches Chem. Gesellschafts*, Berlin, ii, 1869, p. 763; *München Acad. Sitzungsber.* 1870, i, p. 408; *American Journal of Science*, i, 1870, p. 116; *Scientific American*, 1874, p. 177; *Proceedings of American Academy*, viii, 1870, 280. His works have been collected and printed by Dr James Young and Dr Angus Smith, the latter contributing to the volume a valuable preface and analysis of its contents.

GRAHAM, JAMES (1765-1811), author of *The Sabbath* and other poems, was born at Glasgow, April 22, 1765. His father was a successful lawyer, and, by a very common error, he conceived that no other profession could be so suitable or so advantageous for his son. James, dutiful, and shrinking from opposition, as he did all through life, obeyed the paternal wish, and after completing his literary course at the university of his native city, went in 1784 to Edinburgh where he studied law, first to qualify himself for the business of a writer to the signet, and subsequently for the Scottish bar, of which he was elected a member in 1795. His inclinations, however, were all for retirement and literature, and finally, when he had reached the mature age of forty-four, he took orders in the English Church, and became curate first at Shipton, Gloucestershire, and then at Sedgfield in the county of Durham. He did not long enjoy an office which he adorned by his pious and eloquent ministrations. Ill health compelled him to try the renovating effects of his native air, but he died shortly after his return, September 14, 1811. His works of Graham consist of a dramatic poem *Mary Queen of Scots* (published in 1801), *The Sabbath* (1804),

British Grogues (1801), *The Birds of Scotland* (1806), and *Poems on the Abolition of the Slave Trade* (1810). His principal work is *The Sabbath*—a sacred and descriptive poem in blank verse, characterised by a fine vein of tender and devotional feeling, and by the happy delineation of Scottish scenery. He is the Cower of Scotland, but wants Cower's mastery of versification and easy idiomatic vigour of style. The blank verse of Grahame is often hard and contrived, though at times it swells out into periods of striking imagery and prophet like earnestness. His description of the solemn stillness and unbroken calm of "the hallowed day" in the rural districts of Scotland, and of the Scottish Sabbath preachings among the hills in times of persecution, when

"The wretched few would meet in some deep dell
By rocks of craggy shape,"

are finished pictures that will never fade from our poetry. In his *Grogues* he treads the wider field of rural occupations and mœurs, and produced some pleasing daguerotypes of nature,—but he was as careful as well as loving student,—but descended too much into minute and undignified detail. In the notes to his poems he expresses manly and enlightening views on popular education, the criminal law, and other public questions. He was emphatically a friend of humanity—a philanthropist, as well as a poet.

GRAHAM'S TOWN, the metropolis of the eastern districts of the Cape Colony, South Africa, is situated in the division of Albany, 80 miles inland from Algoa Bay, 40 miles inland from Port Alfred, and 600 miles from Cape Town. In 1812 the site of the town was first chosen as the headquarters of the British troops engaged in protecting the frontier of the colony from the incursions of the Kaffre tribes, and it was named after Colonel Graham, then commanding the forces. In 1819 an attempt was made by the Kaffres to surprise the place, and a body of 10,000 men attacked it, but were gallantly repulsed by the garrison, which numbered not more than 320 men, infantry and artillery, under Colonel Wilmshurst. From 1820 Graham's Town was the centre of what was termed the "Albany Settlement," and it soon became the chief emporium of frontier trade. The town is built in a basin of the grassy hills forming the spurs of the Zuurberg mountain range, 1760 feet above sea-level. It is a pleasant place of residence, and is regarded as the most English-like town in the colony. The streets are broad, and most of them lined with trees. The principal thoroughfare is the High Street, where stand St George's English Cathedral, built from designs by Sir Gilbert Scott, and Commemoration Chapel, the chief place of worship of the Wesleyans, erected by the British emigrants of 1820. There are no fewer than twelve churches and chapels in Graham's Town—Church of England, Roman Catholic, Wesleyan, Presbyterian, Baptist, and Independent. It is the seat of the Eastern Districts' Court, presided over by a chief judge and two puisne judges. Among the institutions of the town are an excellent public hospital, a lunatic asylum, colleges and grammar schools, a museum and natural history society, a public library, a club, and Masonic, Temperance, and other societies. There is also a botanic garden, in which there is a memorial of Colonel Foulke of the 74th regiment, who fell in the Kaffre war of 1815. The population of Graham's Town, according to the last census, is 7000. It is the centre of trade for an extensive pastoral and agricultural country, and has easy communication both with Port Alfred, at the mouth of the Kowie River, and with Port Elizabeth on Algoa Bay.

GRAIL, or GRAYT, THE HOLY (Saint Greal, Seynt Greal, Saingael, Sank Nyal), the name given to the legendary wonder-working vessel said to have been brought by Joseph of Arimathea to Britain. The correct spelling is "Greal."

In the present article the subject will be considered under the following four heads—(1) the meaning of the Greal conception; (2) the authorship of the conception; (3) the meaning of this word; (4) the spread of the conception from the land of its origin to other countries.

1 The "Saint Greal" was the name given—if not originally, yet very soon after the conception was stated—to the dish, or shallow bowl (in French, *assiette*), from which Jesus Christ was said to have eaten the paschal lamb on the evening of the Last Supper with his disciples. In the French prose romance of the *Saint Greal*, it is said that Joseph of Arimathea, having obtained leave from Pilate to take down the body of Jesus from the cross, proceeded first to the upper room where the supper was held and found there this vessel, then, as he took down the Lord's dead body, he received into the vessel many drops of blood which issued from the still open wounds in his feet, hands, and side. This last feature, which Tennyson in his beautiful idyll *The Holy Grail* has overlooked, is obviously of the essence of the conception. According to Catholic theology, where the body or the blood of Christ is, there, by virtue of the hypostatic union, is His soul and His divinity. That the Greal, such being its contents, should be marvellous—divine—mysterious, was but logical and natural. The Greal was "the commencement of all noble enterprise, the occasion of all prowess and heroic deeds, the investigation of all the sciences, the demonstration of great virtues, the end of all bounty and goodness, the marvel of all other marvels." Nascene, taking off the paten which covered the Greal, comprehends innumerable marvels, but is struck blind. By the Greal Joseph's life is sustained in prison during forty-two years without food, while as an oracle it instructs him in heavenly knowledge. Nothing could be more fantastic and extravagant than all this, were the Greal conceived of merely as a relic, however venerable, but all is altered when it is brought into close relation, according to the design of its inventors, with the mystery of the eucharist.

2 The authorship of the conception involves one of the most difficult literary questions. Mr. Price, in the able and eloquent dissertation prefixed to vol. 1 of Warton's *History of English Poetry*, seems to maintain the view that it can be attributed to no individual, but was the spontaneous outgrowth of a group of widely prevalent superstitions, in all which a magical cup or divining bowl was the central object. Others, as Fausset, Simcock, and Schulz, find the original home of the legend in Provence. Mr. Martin Farr, who has been engaged for nearly forty years in the study of Arthurian romances, and whose latest speculations (*Homages to the Table Round*, v. 352) bear the recent date of 1870, is of opinion that the original conception came from some Welsh monk or hermit who lived early in the 8th century, that its guiding and essential import was an assertion for the British Church of an independent divinity of its Christianity direct from Palestine, and not through Rome, that the conception was embodied in a book, called *Libre Grailis* or *De Grailis*, that this book was kept in secrecy by the British clergy for more than 300 years, from a fear lest it should bring them into collision with the hierarchy and make their orthodoxy suspected, that it came to be known and read in the second half of the 12th century, that a French poet, Robert de Boron, who probably had not seen the book, but received information about it, was the first to embody the conception in a voluminous literary form by writing his poem of *Joseph d'Armathea*, and that, after Boken, Walter Map and others came into the field in the 12th century, but by English writers generally, that the conception was certainly on British ground, but in the 12th century, not in the 8th; that it was introduced by some master hand, probably that of Walter Map, into every branch of Arthurian

romances, and that if Map was not the author of the conception, as seems highly probable, he first, by writing the French romances of the *Saint Graal*, the second part of *Lancelot*, and *Mort Artu*, invested it in literary form.

These theories cannot be discussed here, but it may be remarked that, in order to pave the way for any rational theory, it is indispensable to have a clear view of the condition of romance literature at and before the time when the conception arose. The legend of Arthur, which barely rises to the surface in the narrative of Gildas, had in the time of Nennius (9th century) attained to considerable consistency, and through the appearance of the *Historia Britonum* of Geoffrey of Monmouth, which everywhere excited an extraordinary sensation, had become European. To the Norman and French poets it had become known, long before the appearance of Geoffrey's book, through the Breton lays, and the mysticism, the tender depths of sentiment, the wild flights of imagination and fancy which were found in these lays, had so captivated and dazzled them as to induce them almost to desert their own rough *Chansons de Geste*, of which Charlemagne was the chief figure, for this new field. A succession of startling incidents, in which giants, knights, dwarfs, fauns, and goblins were actors, and a native in mystic sympathy with man was the background, appealed to the feelings of wonder and awe, the instinct of revenge and the lust of war were gratified by little results innumerable, while around the chief characters of the legends there floated the rapture and the hypothesis of amorous passion. In the *Dist of Wales*, founded on Geoffrey's work, we find the story of Arthur in ample proportions, and the "Round Table" appears for the first time—

"First was Briton in the Rumble Table,
Dunt Briton dunt muntis fabli."

The exuberance of invention here attributed to the Bretons was faithfully imitated by the poets of northern France. Christian of Troyes, born near the middle of the 12th century, besides verifying many tales from Ovid, introduced parts of the Arthur legend in his poem on *King Mark and Ysaient the Blonde*, and the *Chevalier au Lion*. In these, however, there is no mention of the Graal. Suddenly a narrative, possibly in Latin but more probably in French prose, makes its appearance, containing the story of the communion of the Holy Graal to Joseph of Arimathea, as given above, of his subsequent adventures in Syria and elsewhere, and of the ultimate arrival of his son, his brother-in-law, and others of his kindred, in Britain, where they settle in the island of Avalon. The birth of Arthur is prophesied in this narrative, but otherwise he is scarcely mentioned. About the same time, the prose romances of *Lancelot* (part 1) and *Tristan*, containing rich developments of the Arthurian legend, made their appearance and were warmly welcomed. The first is ascribed in the MSS. to Walter Map, and the second to Luce or Lucan de Gast, but both statements, in the opinion of M. Paulin Paris, are extremely doubtful. At any rate, if Map wrote the first part of *Lancelot*, he continued and finished it in a totally different spirit. The first part is mere love and chivalry, "the most secular," says M. Paulin Paris, "of all romances," while the second part is the most mystical of all. The first part contains no allusion to the Graal, in the second it is an element of overpowering interest. Lancelot joins in the quest for the Graal, fails to see it or only half sees it, repents, becomes a holy hermit, and dies. *Tristan* in its original form was the legend of a favorite Breton hero, it was then connected with the cycle of Arthur, lastly, perhaps by the same powerful hand that transmuted *Lancelot*, it was brought within the sweep of the Graal conception. But who invented the story of Joseph of Arimathea? or rather, who connected that story with the Graal legend, and

both with Arthur? The importance of a work of William of Malmesbury in assisting us to answer this question has been somewhat overlooked. In his treatise *De Antiquitate Glastoniensis Ecclesie*, written probably soon after Henry of Blois, abbot of Glastonbury, to whom it is dedicated, was raised to the see of Winchester (1129), Malmesbury records with considerable detail the legend which brought Joseph to Glastonbury, and made him the first preacher of Christianity to the Britons. Everything connected with Glastonbury had a duodenary character, Joseph was sent to Britain by St. Philip the evangelist as the chief among twelve missionaries, the holy men who afterwards tenanted the abbey always sought to maintain the number of twelve, Glaston, from whom the place was named, was one of twelve brothers, the chief estate of the abbey was called "the Twelve Hides," &c. This same feature distinctly reappears in the Graal legend, where Bion, the brother-in-law of Joseph, has twelve sons, who are all sent to Britain, but one among them, Alain, who renounces marriage, is set over the rest. Again, we read in Malmesbury that Avalon is another name for Glastonbury, and in the Graal legend we read that Joseph's kindred are directed by a divine voice to seek, in the far west, the "valleys of Avalon." Lastly, in the strange story about the alms called "sapphirus," which angels brought from Palestine to St. David, and which after a long disappearance was rediscovered in Malmesbury's own day, we seem to lay our finger, as it were, on the origin, the rudimentary suggestion, of the Graal conception.

Now if we accept the general testimony of the MSS., and assume without further proof that Map composed, whether in Latin or in French, the original book of the *Saint Graal*, the genesis of the work seems not difficult to trace. In early life Map was a canon of Salisbury (see Wright's preface to the *De Ysaie Curialium*), either afterwards or at the same time he was parish priest of Westbury near Bristol. Gloucestershire and Wiltshire are both neighboring counties to Somersetshire, in which Glastonbury was the most sacred and celebrated spot. Visiting that ancient abbey, Map would have become acquainted with the legend of Joseph of Arimathea in all its details, and he would have seen the altar and to have been transported by angels from Palestine, and which, long hidden from mortal sight on account of the wickedness of the times, had lately been revealed and reinstated. His versatile and capacious mind would, as a matter of course, have been familiar with the whole Arthur legend as it then (1170-1180) existed, if for no other reason, because he lived in the very part of England which was studded with Arthurian sites. He fully answers to the description of the "great clerk" who, according to Robert de Boron first made and told the history of the Graal. He seems to have conceived the vast design of steeping the Arthurian legend, and through it the whole imaginative literature of the age, in the doctrine of the Christian sacrifice. He is generally credited in the MSS. with the composition of the *Saint Graal* (containing the legend of Joseph of Arimathea), of the *Quest of the Saint Graal*, of *Lancelot* in whole or in part, and of the *Mort Artu*. But it appears that no MS. of any of these romances now exists of an earlier date than 1274, and it is certain that a set of "airanges" and continuators (like the rhapsodists and cyclic poets of the Homeric epics) commenced their continuing operations on the legend at an early period. Hence it seems impossible now to recover the exact order in which the different romances were composed. On the origin of the word Graal, the opinion of M. Paulin Paris seems to be satisfactory. He thinks that graal is a corruption of gualde, or graduals, the Latin name for a liturgical collection of psalms and texts of scripture, so called "quod in gradibus cantur," as the priest is passing

from the epistle to the gospel side of the altar. The author of the Grial conception must by grial, or gradale, not the sacred dish (escudelle), but the mysterious book revealed to the supposed hermit of 717, in which he finds the history of the esculle Robert de Boron, mistaking this, transfers the name to the dish, and connects it with *gri* (gratus, gratia) on account of the inward solace connected with it (see *Romans de la T R*, i 143). The word rapidly became popular in the sense of bowl, or shallow cup, so that Hilaund (1204) could say, "Dicitur vulgari nomine *grials*, quia grata et acceptabilis est in ea comedens." This etymology is the same as Boron's. The older French word *griuel*, meaning service-bowl (Duong, article "Gradale"), was displaced by the new *grial* or *greal*. On the other hand, M. Fauvel derives *grial* from an old Provençal word for a cup, *griand*. But this *griand*, according to the article in Duong, seems to be of Armenian origin, anyhow M. Fauvel has not proved its use in the sense of cup at a period earlier than the use of the Grial legend.

4 The spread and ascendancy to which the Grial conception rapidly attained in all Christian countries made the creations of Arthurian romance the delight of all cultivated minds, from Caesalon to Venice, and from Iceland to the Straits of Gibraltar. From England, which we must regard as the land of its origin, the Grial legend at once passed to France, and found an enthusiastic and capable interpreter in Robert de Boron. This Boron was no Englishman of Nottinghamshire, as some English writers have pretended, but, as Paulin Paris conclusively proves, a French poet of the county of Montbeliard in the region of the Vosges. Christien de Troyes in his *Perceval* (written before 1191, for it is dedicated to Count Philip of Flandris who died in that year), gives in a metrical dress the legend of Perceval, one of the knights of the round table, under the transformation which the introduction of the Grial conception had effected. The continuations of the poem, by Denet and Manessier, come down to about 1240. The famous Mid-German poem of *Parzival*, by Wolfram von Eschenbach, which appeared near the beginning of the 13th century, is founded partly on Christien's *Parzival*, but partly also on some other, perhaps Provençal, source, which is now lost. A rude English metrical version of the French prose romance of the *Saint Grial*, by one Harry Langsch, dating from the reign of Henry VI, has been recently edited by Mr Fumvall for the Roxburgh Club. Flemish, Icelandic, and Welsh reproductions of the Grial romances have been found to exist. One of the first employments of the printing press in England, France, and Germany was to multiply poems or romances embodying this legend. Hence Caxton printed for St Thomas Malory (1485) *The History of King Arthure and his Noble Knights*, a version in English prose of the French romances of *Merlin*, *Lancelot*, *Tristan*, the *Queste du Saint Grial*, and *Mort Artus*, all at any rate based upon them. An early French edition of the *Tristan*, of which there is a copy in the British Museum, is dated 1489. *Lancelot du Lac* was printed at Paris in 1513, and not long afterwards editions of the *Tristan* and other portions of the Arthur cycle, always as incorporated by the Grial legend, appeared both in Italy and Spain (Schulz's *Essay*, p 114).

See Paulin Paris, *Les Manuscrits de la Bibliothèque Royale*, 1836, and *Les Romans de la Table Ronde*, 1868-77. Madden's *His Genealogy*, edited for the Roxburgh Club, 1889, the *Saint Greal* (part 1), edited by F Fumvall, with a preface essay, on the Grial saga by San Mute (Schulz), 1861-3, several MSS of the King's Library in the British Museum, Reg 14 R, in 19 C, in 20 C v, &c. &c. Fauvel's *Hist de la Table Ronde*, Wolfram von Eschenbach, *Parzival* and *Artus*, edited by F. H. Schulz, 1870, Watson's *History of English Poetry*, vol 1, *Le Roman de Tristan*, vol 2, *Merlin*, "Chromace" (in *Alcuin's Patrologia*, vol cxxv), Schulz's *Essay on the Influence of Welsh Tradition*, London, 1841, &c, &c.

GRAINS OF PARADISE, GUINEA GRUINS, or MELP-CUTTA PAPPA (German, *Paradieskörner*), French, *Graines de Paradis*, *Manynette*), the *semen carolinum myrsin* or *myrsin melaguetia* of pharmacists, are the seeds of *Alouatta Melegueta*, Roscoe, a root-like plant of the natural order *Zingiberaceae*, which is a native of tropical western Africa, and of Pines and St Thomas's Islands in the Gulf of Guinea, is cultivated in British Guiana, and may with ease be grown in hot houses in England. The plant has a branched horizontal rhizome, smooth, newly several, alternate leaves, with the blade oblong-lanceolate, large, white, pale pink, or purplish flowers, and an ovate oblong fruit, embedded in bracts, which is of a scarlet colour when fresh, and reaches under cultivation a length of 5 inches. The seeds are contained in the acid pulp of the fruit, are commonly wedge-shaped and bluntly angular, are about 1½ line in diameter, and have a glossy dark-brown husk, with a conical light-coloured membranous caruncle at the base, and a white kernel. They contain, according to Kluckiger and Haubny, 0.3 per cent of a faintly yellowish neutral essential oil, having an aromatic, not acid taste, and a specific gravity at 15.5° C of 0.823, and giving on analysis the formula $C_{20}H_{14}O_2$, or $C_{20}H_{16}O + C_2H_4O$, also 5.83 per cent of an intensely pungent, viscid, brown resin. Grains of paradise were formerly official in the British pharmacopoeia, and in the 13th and 14th centuries were used as a drug, and a spice, the wine known as hippocras being flavoured with them and with ginger and cinnamon. In 1839 they were employed among the ingredients of the twenty-four bering pills which were the ancient fee favour of the city of Norwich, ordained to be carried to court by the lord of the manor of Chilton (Johnson and Church, *Chem of Common Life*, p 355, 1879). Grains of paradise were in past times brought overland from West Africa to the Mediterranean ports of the Barbary States, to be shipped for Italy. They are now exported almost exclusively from the Gold Coast. The amount received by Great Britain in 1871 was upwards of 700 cwt. Grains of paradise are to some extent used in veterinary practice, but for the most part illegally to give a fictitious strength to malt, liquor, gin, and cordials. 56 Geo III c 58, no brewer or dealer in beer shall have in his possession or use grains of paradise, under a penalty of £200 for each offence, and no druggist shall sell the same to a brewer under a penalty of £500. They are, however, devoid of any injurious physiological action, and are much esteemed as a spice by the natives of Guinea.

See Bentley and Tinsley, *Medicinal Plants*, part 10, tab 268, Linnæus, *Hist des Drogues*, pp 154-160, 2578.

GRAM, or CHITRA PPA, called also Egyptian PEA, or Bengali Gram (*Hind, chana*, Bengali, *chhoda*, Malian, *cece*, Spanish, *garbanzo*), an herbaceous, annual, leguminous plant, the *Cicer arietinum* of Linnæus, is named from the resemblance of its seed to a ram's head, is a native of the south of Europe and India. Its leaves are impinnate, with ovate, equal, and serrate leaflets, the flowers are axillary, and of a bluish-purple colour, and bloom in India from September to October, and the pods have a length of 1 to 1½ inch, and contain either one or two somewhat pointed and commonly pale yellow seeds, about 3 lines long. Gram is largely cultivated in the East, where the seeds are eaten raw, or cooked and prepared in various ways, both in their ripe and unripe condition, and when roasted and ground are made to subserve the same purposes as ordinary flour. In Europe the seeds are used as an ingredient in soups. They contain, in 100 parts, without husk, nitrogenous substances 22.7, fat 3.76, starch 63.18, mineral matters 2.6 parts, with water (Forbes Watson, quoted in J. E. Smith's *Lignette*). The liquid which exudes from the glandular hairs clothing the leaves and stems of the plant, more

especially during the cold season, when the seeds ripen, contains a notable proportion of oxalic acid, and is said to be very injurious to the lenticular shoes of those who walk through fields of gram. In Mysore the dew containing it is collected by means of cloths spread on the plant over night, and is valued as a remedy for dyspepsia, indigestion, and costiveness. The steam of water in which the fresh plant is immersed is in the Deccan resorted to by the Portuguese for the treatment of dysmenorrhoea. The seed of *Phaseolus Mungo*, Linn, or green gram (Hind and Beng, *moong*), a variety of which plant, *P. Mungo melanopermar* (P. *Mei*, Roeb.), is termed black gram, is an important article of diet among the labouring classes in India, and is annually exported in large quantities from Madras. Soup made from it is considered to be especially suited to sick persons. The meal is an excellent substitute for soap, and is stated by Elliot to be an invaluable concomitant of the Hindu bath. *P. Radburghia*, W and Arn., or *P. radiatus*, Roeb (Hind, *urid*, Beng, *radhi*, *haldi*), which also is known as green gram, is perhaps the most esteemed of the leguminous plants of India, where the meal of its seed enters into the composition of the most delicate cakes and dishes, and is used in medicine both externally and internally. *P. acutifolius* goes by the name of Turkish gram. Horse gram, *Dolichos uniflorus*, Linn (Hind and Beng, *kudhi*), which is sown in Madras the place of the chick-pea, affords seed which, when boiled, is extensively employed as a food for horses and cattle in South India, where also it is eaten in curries, and, made into poultices or pastes, is applied to medicinal purposes. Turkish gram is the *Dolichos Catang* of Rortburgh. White gram, *Clypeus* (*Squa*) *hispida*, produces the beans from which soy is made. The quantity of gram exported from India in 1876-77, chiefly to Mauritius, Ceylon, and the Straits, amounted to 316,692 cwt, against 322,061 cwt in the previous year.

GRAMMAR. By the grammar of a language is meant either the relations borne by the words of a sentence and by sentences themselves one to another, or the systematized exposition of these. The exposition may be, and frequently is, incorrect, but it always presupposes the existence of certain customary uses of words when in combination. In what follows, therefore, grammar will be generally employed in its primary sense, as denoting the mode in which words are connected together in order to express a complete thought, or, as it is termed in logic, a proposition.

The object of language is to convey thought, and so long as the object is attained the machinery for attaining it is of comparatively slight importance. The way in which we combine our words and sentences matters but little, provided that our meaning is clear to others. The expressions "horse-flesh," and "flesh of a horse," are equally intelligible to an Englishman and therefore are equally recognized by English grammar. The Chinese manner of denoting a genitive is by placing the defining word before that which it defines, as in *howe-jin*, "man of the kingdom," literally "kingdom man," and the only reason why it would be incorrect in French or Italian is that such a combination would be unintelligible to a Frenchman or an Italian. Hence it is evident that the grammatical correctness or incorrectness of an expression depends upon its intelligibility, that is to say, upon the ordinary use and custom of a particular language. Whatever is so unfamiliar as not to be generally understood is also ungrammatical. In other words, it is contrary to the habit of a language, as determined by common usage and consent.

In this way we can explain how it happens that the grammar of a cultivated dialect and that of a local dialect in the same country so frequently disagree. Thus, in the dialect of West Somerset, *thee* is the nominative of the second personal pronoun, while in cultivated English the plural accusative *you* (Anglo-Saxon, *tu*) has come to represent a nominative singular. Both are grammatically correct within the sphere of their respective dialects, but no further. *You* would be as ungrammatical in West Somerset as *thee* is in classical English, and both *you* and *thee*, as nominatives singular, would have been equally ungrammatical in Early English. Grammatical propriety is nothing more than the established usage of a particular body of speakers at a particular time in their history.

It follows from this that the grammar of a people changes, like its pronunciation, from age to age. Anglo-Saxon or Early English grammar is not the grammar of Modern English, any more than Latin grammar is the grammar of modern Italian, and the defence of an unusual construction or inflexion on the ground that it once existed in literary Anglo-Saxon, is as wrong as to import a peculiarity of some local dialect into the grammar of the cultivated speech. It further follows that different languages will have different grammars, and that the differences will be more or less according to the nearer or remoter relationship of the languages themselves, and the mode of thought of those who speak them. Consequently, to force the grammatical framework of one language upon another is to misconceive the whole nature of the latter, and seriously to mislead the learner. Chinese grammar, for instance, can never be understood until we discard, not only the terminology of European grammar, but the very conceptions which underlie it, while the polysynthetic idioms of America defy all attempts to discover in them "the parts of speech" and the various grammatical ideas which occupy so large a place in our school-grammars. The endeavour to find the distinctions of Latin grammar in that of English has only resulted in grotesque errors, and a total misapprehension of the usage of the English language.

It is to the Latin grammarians, — or, more correctly, to the Greek grammarians, upon whose labours those of the division of Latin writers was based, — that we owe the classification of the subjects with which grammar is commonly supposed to deal. The grammar of Dionysius Thrax, which he wrote for Roman schoolboys in the time of Pompey, has formed the starting point for the innumerable school grammars which have since seen the light, and suggested that division of the matter treated of which they have followed. He defines grammar as a practical acquaintance with the language of literary men, and as divided into six parts, — accentuation and phonology, explanation of figurative expressions, definition, etymology, general rules of flexion, and critical canons. Of these, phonology and accentuation, or prosody, can properly be included in grammar only in so far as the construction of a sentence and the grammatical meaning of a word are determined by accent or letter-change, the accentual difference in English, for example, between *facience* and *incense* belongs to the province of grammar, since it indicates a difference between noun and verb, and the changes of vowel in the Semitic languages, by which various nominal and verbal forms are distinguished from one another, constitute a very important part of their grammatical machinery. But where accent and pronunciation do not serve to express the relations of words in a sentence, they fall into the domain of phonology, not of grammar. The explanation of figurative expressions, again, must be left to the rhetorician, and definition to the lexicographer, the grammarian has no more to do with them than he has with the canons of criticism.

In fact, the old subdivision of grammar, inherited from

the grammarians of Rome and Alexandria, must be given up, and a new one put in its place. What grammar really deals with are all those contrivances, whereby the relations of words and sentences are pointed out. Sometimes it is position, sometimes phonetic symbolization, sometimes composition, sometimes flexion, sometimes the use of auxiliaries, which enables the speaker to combine his words together so that they shall be intelligible to another. Grammar may accordingly be divided into the three departments of composition or "word building," syntax, and accentuation, by which is meant an exposition of the means adopted by language for expressing the relations of grammar when recourse is not had to composition or simple position.

A systematized exposition of grammar may be intended for the purely practical purpose of teaching the mechanism of a foreign language. In this case, all that is necessary is a correct and complete statement of the facts. But a correct and complete statement of the facts is by no means so easy a matter as might appear at first sight. The facts will be distorted by a false theory in regard to them, while they will certainly not be presented in a complete form if the grammarian is ignorant of the true theory they presuppose.

The Sanskrit verb, for example, remains unintelligible so long as the explanation of its forms is sought in the conjugation of the Aryan verb, since it has no tenses in the Aryan sense of the word, but denotes relation and not time.

A good practical grammar of a language, therefore, should be based on a correct appreciation of the facts which it expounds, and a correct appreciation of the facts is only possible where they are examined and co-ordinated in accordance with the scientific method. A practical grammar ought, whenever it is possible, to be preceded by a scientific grammar.

Comparison is the instrument with which science works, and a scientific grammar, accordingly, is one in which the comparative method has been applied to the relations of speech. If we would understand the origin and real nature of grammatical forms, and of the relations which they represent, we must compare them with similar forms in kindred dialects and languages, as well as with the forms under which they appeared themselves at an earlier period of their history. We shall then have a comparative grammar and an historical grammar, the latter being devoted to tracing the history of grammatical forms and usages in the same language. Of course, an historical grammar is only possible where a succession of written records exists, while a language possesses no older literature, we must be content with a comparative grammar only, and look to cognate idioms to throw light upon its grammatical peculiarities. In this case we have frequently to leave whole forms unexplained, or at most conjecturally interpreted, since the machinery by means of which the relations of grammar are symbolized is often changed so completely during the growth of a language as to cause its earlier shape and character to be unrecognizable. Moreover, our area of comparison must be as wide as possible, where we have but two or three languages to compare, we are in danger of building up conclusions on insufficient evidence. The grammatical errors of the classical philologists of the last century were in great measure due to the fact that their area of comparison was confined to Latin and Greek.

The historical grammar of a single language or dialect, which traces the grammatical forms and usages of the language as far back as documentary evidence allows, affords material to the comparative grammarian, whose task it is to compare the grammatical forms and usages of an allied group of tongues, and thereby reduce them to their earliest forms and senses. The work thus carried out by the comparative grammarian within a particular family of languages is made use of by universal grammar, the object of which

is to determine the ideas that underlie all grammar whatsoever, as distinct from those that are peculiar to special families of speech. Universal grammar is sometimes known as "the metaphysics of language," and it has to decide such questions as the nature of gender, or of the verb, the true purport of the genitive relation, or the origin of grammar itself. Such questions, it is clear, can only be answered by comparing the results gained by the comparative treatment of the grammars of various groups of language. What historical grammar is to comparative grammar, comparative grammar is to universal grammar.

Universal grammar, as founded on the results of the Universal scientific study of speech, is thus essentially different from grammar that "universal grammar" so much in vogue at the beginning of the present century, which consisted of a series of *a priori* assumptions based on the peculiarities of European grammar and illustrated from the same source. But universal grammar, as conceived by modern science, is as yet in its infancy, its materials are still in the process of being collected. The comparative grammar of the Aryan languages is alone in an advanced state, those of the Semitic idioms, of the Ugro-Altaic tongues, and of the Basile or Kaffio dialects of southern Africa, are still in a backward condition, and the other families of speech existing in the world, with the exception of the Malay-Polynesian, and the Sonoran of North America, have not as yet been treated scientifically. Chinese, it is true, possesses an historical grammar, and Mr. Van Eya, in his comparative grammar of Basque, has endeavored to solve the problems of that interesting language by a comparison of its various dialects, but in both cases the area of comparison is too small for more than a limited success to be attainable. Instead of attempting the questions of universal grammar therefore, it will be better to confine our attention to three points, — the fundamental differences in the grammatical occupations of different groups of languages, the main results of a scientific investigation of Aryan grammar, and the light thrown by comparative philology upon the grammar of our own tongue.

The proposition or sentence is the unit and starting point of speech, and grammar, as we have seen, consists in the relations of its several parts one to another, together with the expression of them. These relations may be regarded from various points of view. In the polysynthetic languages of America the sentence is conceived as a whole, not composed of independent words, but, like the thought which it expresses, one and indivisible. What we should denote by a series of words is consequently denoted by a single long compound, — *Indiyahav in* I declare, for instance, signifying "give me your pretty little pan," and *oyfillaquetvay cawesupet*, in Eskimo, "he goes away hastily and returns himself to write." Individual words can be, and often are, extracted from the sentence, but in this case they stand, as it were, outside it, being represented by a pronoun within the sentence itself. Thus, in Mexican, we can say not only *me sosa temoa*, "I look for flowers," but also *me k'k'ommetet*, where the interpolated *guth* it is the objective, *pro* noun. As a necessary result of this conception of the sentence the American languages possess no true verb, each act being expressed as a whole by a single word. In Chinook, for example, while there is no verb signifying "to wash" in the abstract, no less than thirteen words are used to signify every conceivable mode and object of washing. In the incorporating languages, again, of which Basque may be taken as a type, the object cannot be conceived except as contained in the verbal action. Hence every verbal form embodies an objective pronoun, even though the object may be separately expressed. If we pass to an isolating language like Chinese, we find the exact converse of that which meets us in the polysynthetic tongues. Here each proposi-

Notes on
treat
ment

tion or thought is analysed into its several elements, and these are set over against one another as so many independent words. The relations of grammar are consequently denoted by position, the particular position of two or more words determining the relation they bear to each other. The analysis of the sentence has not been carried so far in agglutinative languages like Turkish. In these the relations of grammar are represented by individual words, which, however, are subordinated to the words expressing the main ideas intended to be in relation to one another. The defining words, or indices of grammatical relations, are, in a large number of instances, placed after the words which they define, in some cases, however, as, for example, in the Dikru languages of southern Africa, the relation is conveyed from the opposite point of view, the defining words being prefixed. The inflexional languages call in the aid of a new principle. The relations of grammar are denoted symbolically either by a change of vowel or by a change of termination, more rarely by a change at the beginning of a word. Each idea, together with the relation which it bears to the other ideas of a proposition, is thus represented by a single word, that is to say, the ideas which make up the elements of a sentence are not conceived severally and independently, as in Chinese, but as always having a certain connection with one another. Inflexional languages, however, tend to become analytical by the logical separation of ideas from the flexion from which it is attached, though the primitive point of view is never altogether discarded, and traces of flexion remain even in English and Persian. In fact, there is no example of a language which has wholly forsaken the conception of the sentence and the relation of its elements with which it started, although each class of languages occasionally trespasses on the grammatical usages of the others. In language, as elsewhere in nature, there are no sharp lines of division, no sudden leaps, species passes insensibly into species, class into class. At the same time the several types of speech—polysynthetic, isolating, agglutinative, and inflexional—remain clear and fixed, and even where two languages belong to the same general type, as, for instance, an Aryan and a Semitic language in the inflexional group, or a Kaffro and a Turkish language in the agglutinative group, we find no certain example of grammatical interchange. A mixed grammar, in which the grammatical procedure of two distinct families of speech is unmingled, is almost, if not altogether, unknown.

It is obvious, therefore, that grammar constitutes the surest and most important basis for a classification of languages. Words may be borrowed freely by one dialect from another, or, though originally unrelated, may, by the action of phonetic decay, come to assume the same forms, while the limited number of articulate sounds and conceptions out of which language was first developed, and the similarity of the circumstances by which the first speakers were everywhere surrounded, naturally produce a resemblance between the roots of many unconnected tongues. Where, however, the fundamental conceptions of grammar, and the machinery by which they are expressed are the same, we may have no hesitation in inferring a common origin.

The main results of scientific inquiry into the origin and primitive meaning of the forms of Aryan or Indo-European grammar may be summed up as follows. We start with stems or themes, by which are meant words of two or more syllables which terminate in a limited number of sounds. These stems can be classed in groups of two kinds, one in which the groups consist of stems of similar meaning and similar initial syllables, and another in which the final syllables alone coincide. In the first case we have what are termed roots, the simplest elements into which words can be decomposed, in the second case stems proper, which may be described as consisting of suffixes attached to roots,

Roots, therefore, are merely the materials out of which speech can be made, the embeddings of isolated conceptions with which the lexicon supplied alone is too dull, & useless stems present us with words, already combined in a sentence and embodying the relations of grammar. If we would rightly understand primitive Aryan grammar, we must conceive it as having been expressed or implied in the suffixes of the stems, and in the order according to which the stems were arranged in a sentence. In other words, the relations of grammar were denoted partly by juxtaposition or syntax, partly by the suffixes of stems.

These suffixes were probably at first unmeaning, or rather clothed with vague significations, which changed according to the place occupied in the sentence by the stem to which they were joined. Gradually this vagueness of signification disappeared, and particular suffixes came to be set apart to represent particular relations of grammar. What had hitherto been expressed by mere position now attached itself to the terminations or suffixes of stems, which accordingly became full grown words. Some of the suffixes denoted purely grammatical ideas, that is to say, were flexions, others were classificatory, serving to distinguish nouns from verbs, presents from aorists, objects from agents, and the like, while others, again, remained unmeaning adjuncts of the root. This origin of the flexions explains the otherwise strange fact that the same suffix may symbolize wholly different grammatical relations. In Latin, for instance, the context and dictionary will alone tell us that *mus* is the accusative plural of a noun, and *am*-is the second person singular of a verb, or that *mus* is the nominative singular of a feminine substantive, *am*-a the accusative plural of a neuter adjective. In short, the flexions were originally merely the terminations of stems which were adapted to express the various relations of words to each other in a sentence, as these gradually presented themselves to the consciousness and were extracted from what had been previously implied by position. Nevertheless, the same suffix might be used sometimes in a classificatory, sometimes in a flexional sense, and sometimes without any definite sense at all. In the Greek dative-locative *πρὸς* *er*-*es*, for example, the suffix *-es* is classificatory, in the nominative *πρὸς* *es*, it is flexional.

When a particular termination or suffix once acquired a special sense, it would be separated in thought from the stem to which it belonged, and attached in the same sense to other stems and other terminations. Thus in modern English we can attach the suffix *-er* to almost any word whatsoever, in order to give the latter a transitive meaning, and the Greek *πρὸς**er**es*, quoted above, really contains no less than three suffixes, *er*-, *es*-, and *-s*, the last two both denoting the locative, and coexisting, though *er*-, is only a single syllable *-er*. The latter instance shows us how two or more suffixes denoting exactly the same idea may be tacked on one to another, if the original force and signification of the first of them comes to be forgotten. Thus, in Old English *sang* *ende* *s* was the feminine of *singer* *-e*, "singer," but the meaning of the termination has so entirely died out of the memory that we have to add the Romance *-es* to it if we would still distinguish it from the masculine *singer*. A familiar example of the way in which the full sense of the exponent of a grammatical idea fades from the mind and has to be supplied by a new exponent is afforded by the use of expletives in conversational English to denote the superlative "Very warm" expresses little more than the positive, and to represent the intensity of his feelings the Englishman has recourse to such expressions as "horribly warm" like the German "schrecklich warm."

Such words as "very," "horribly," "schrecklich," illustrate a second mode in which Aryan grammar has found means of expression. Words may lose their true significa-

tion and become the mere exponents of grammatical ideas Professor Enkle divides all words into *prepositive* and *symbolic*, the former denoting objects and conceptions, the latter the relations which exist between these. Symbolic words, therefore, are what the Chinese grammarians call "empty words,"—words, that is, which have been divested of their proper signification and save a grammatical purpose only. Many of the classificatory and some of the flexional suffixes of Aryan speech can be shown to have had this origin. Thus the suffix *tu*, which denotes names of kinship and agency, seems to come from the same root as the Latin *terminus* and *trans*, our *through*, the Sanskrit *tu* *am*, "I pass over," and to have primarily signified "one that goes through" a thing. Thus, too, the English *head* or *hood*, in "wield like godhead and the other hood," is the Anglo-Saxon *hād*, "character" or "rank" *dem*, in *Lyndom*, the Anglo-Saxon *dōm*, "judgment," and *lock* or *ledge*, in *well-locked* and *know-ledge*, the Anglo-Saxon *lēc*, "spot" or "gift." In all these cases the "empty words," after first losing every trace of their original significance, have followed the general analogy of the language and assumed the form and functions of the suffixes with which they had been confused.

A third mode of representing the relations of grammar is by the symbolic use of vowels and diphthongs. In Greek, for instance, the distinction between the reduplicated present *ἔδωκα*, and the reduplicated perfect *ἔδωκα* is indicated by a distinction of vowel, and in primitive Aryan grammar, the vowel *a* seems to have been set apart to denote the subjunctive mood just as *ya* or *y* was set apart to denote the potential. So, too, according to M. Hovelacque, the change of *a* into *i* or *u* in the parent-Aryan symbolized a change of meaning from passive to active. This symbolic use of the vowels, which is the purest application of the principle of flexion, is far less extensively carried out in the Aryan than in the Semitic languages. The Semitic family of speech is therefore a much more characteristic type of the inflexional languages than is the Aryan.

The primitive Aryan noun possessed at least eight cases,—nominative, accusative, vocative, instrumental, dative, genitive, ablative, and locative. M. Beaugue has attempted to show that the first three of these "the strong cases" as they are termed, are really abstracts formed by the suffixes *-a* (*-s*), *-m*, *-t*, *-i*, *-d*, and *-ya* (*-s*), the plural being nothing more than an abstract singular, as may be readily seen by comparing words like the Greek *ἄνθρωπος* and *ἄνθρωποι*, which mean precisely the same. The remaining "weak" cases, formed by the suffixes *-ana*, *-ya*, *-ya*, *-ya*, *-i*, *-m*, *-t*, *-d*, *-i*, *-a*, and *-d*, are really adjectives and adverbs. No distinction, for example, can be drawn between "a cup of gold" and "a golden cup," and the instrumental, the dative, the ablative, and the locative are, when closely examined, merely adverbs attached to a verb. The terminations of the strong cases do not displace the accent of the stem to which they are suffixed, the suffixes of the weak cases, on the other hand, generally draw the accent upon themselves.

According to Hubschmann, the nominative, accusative, and genitive cases are purely grammatical, distinguished from one another through the exigencies of the sentence only, whereas the locative, ablative, and instrumental have a logical origin and determine the logical relation which the three other cases bear to each other and the verb. The nature of the dative is left undecided. The locative primarily denotes rest in a place, the ablative motion from a place, and the instrumental the means or concomitance of an action. The dative Hubschmann regards as "the case of the participant object." Like Hubschmann, Hovelacque divides the cases into two classes,—the one grammatical and the other logical, and his analysis of their primitive meaning is the same as that of Hubschmann,

except as regards the dative, the primary sense of which he thinks to have been motion towards a place. This is also the view of Delbuck, who makes it denote tendency towards an object. Delbuck, however, holds that the primary sense of the ablative was that of separation, the instrumental originally indicating concomitance, while there was a double locative, one used like the ablative absolute in Latin, the other being a locative of the object.

The dual was older than the plural, and after the development of the latter survived as a merely useless enunciation, of which most of the Aryan languages continued in time to get rid. There are still many savage idioms, in which the conception of plurality has not advanced beyond that of duality. In the Bushman dialects, for instance, the plural, or rather that which is more than one, is expressed by repeating the word, thus *tu* is "month," *tutu* "months." It may be shown that most of the suffixes of the Aryan dual are the longer and more primitive forms of those of the plural which have grown out of them by the help of phonetic decay. The plural of the weak cases, on the other hand (the accusative alone excepted), was identical with the singular of abstract nouns, so far as both form and meaning are concerned, no distinction can be drawn between *eres* and *eros*. Similarly, *humanity* and *man* signify one and the same thing, and the use of English words like *weep* or *fade* for both singular and plural shows to what an extent our appreciation of number is determined by the context rather than by the form of the noun. The so-called "broken plurals" of Arabic and Ethiopic are really singular collectives employed to denote the plural.

Gender is the product partly of analogy, partly of phonetic decay. In many languages such as Eskimo and Chukchaw, its place is taken by a division of objects into animate and inanimate, while in other languages they are separated into rational and irrational. There are many indications that the parent-Aryan in an early stage of its existence had no signs of gender at all. The terminations of the names of *father* and *mother*, *pater* and *mater*, for example, are exactly the same, and in Latin and Greek many diphthongal stems, as well as stems in *s* or *ya* and *hiko* *ra* and *ra* *ra*, *ra* *ra* and *ra* *ra*, may be readily indicated masculine and feminine. Even stems in *o* and *a* (of the second and first declensions), though the first are generally masculine and the second generally feminine, by no means invariably maintain the rule, and feminine like *homo* and *homo*, or masculine like *advena* and *advena*, show that there was a time when these stems also indicated no particular gender, but owed their subsequent adaptation, the one to mark the masculine and the other to mark the feminine, to the influence of analogy. The idea of gender was first suggested by the difference between man and woman, male and female, and, as in so many languages at the present day, was represented not by any outward sign but by the meaning of the words themselves. When once arrived at, the conception of gender was extended to other objects besides those to which it properly belonged. The primitive Aryan did not distinguish between subject and object, but personified objects by ascribing to them the motives and powers of living beings. Accordingly they were referred to by different pronouns, one class denoting the masculine and another class the feminine, and the distinction that existed between these two classes of pronouns was after a time transferred to the nouns. As soon as the preponderant number of stems in *o* in daily use had come to be regarded as masculine on account of their meaning, other stems in *o*, whatever might be their signification, were made to follow the general analogy, and were similarly classed as masculine. In the same way, the suffix *s* or *ya* acquired a feminine sense, and was set apart to represent the feminine gender. Unlike the Semites, the Aryans were not satisfied with these two

genders, masculine and feminine. As soon as object and subject, patient and agent, were clearly distinguished from each other, there arose a need for a third gender, which should be neither masculine nor feminine, but denote things without life. This third gender was fittingly expressed either by the objective case used as a nominative (*ε γ, ενιπνιμ*), or by a stem without any case ending at all (*ε γ, ενιπν*).

The adverbial meaning of so many of the cases explains the readiness with which they became crystallized into adverbs and prepositions. An adverb is the attribute of an attribute,—"the rose smells sweetly," for example, being resolvable into "the rose has the attribute of scent with the further attribute of sweetness." In our own language *ones, times, needs*, are all genitives, *whom* is a dative. The Latin and Greek *humi* and *χαμας* are locatives, *fructum* (*fructum*) and *δουλον* are ablatives, *πάντῃ* and *ἀμα* instrumentals, *πίπρος*, *ἔξῃς*, and *ῥηλός* genitives. The frequency with which particular cases of particular nouns were used in a specially attributive sense caused them to become, as it were, petrified, the other cases of the nouns in question passing out of use, and the original force of those that were retained being gradually forgotten. Prepositions are adverbs employed to define nouns instead of verbs and adjectives. Their appearance in the Aryan languages is comparatively late, and the Illyrian poems allow us to trace their growth in Greek. The adverb, originally intended to define the verb, came to be construed with the noun, and the government of the case with which it was construed was accordingly transferred from the verb to the noun. Thus when we read in the *Odyssey* (iv 43), *ἀνδρὸς δ' ὀπίσσω θεῶν δόμοις*, we see that *εἰς* is still an adverb, and that the accusative is governed by the verb, it is quite otherwise, however, with a line like *Ἀργεῖος δὲ γέροντας δόλλας ἦεν Ἀχαιῶν ἐκ λίσσιν* (II, i 59) where the adverb has passed into a preposition. The same process of transformation as still going on in English, where we can say indifferently, "What are you looking at?" using "at" as an adverb, and governing the pronoun by the verb, and "At what are you looking?" where "at" has become a preposition. With the growth and increase of prepositions the need of the case endings diminished, and in some languages the latter disappeared altogether.

Like prepositions, conjunctions also are primarily adverbs used in a demonstrative and relative sense. Hence most of the conjunctions are petrified cases of pronouns. The relation between two sentences was originally expressed by simply setting them side by side, afterwards by employing a demonstrative at the beginning of the second clause to refer to the whole preceding one. This relative pronoun can be shown to have been in the first instance a demonstrative, indeed, we can still use *that* in English in a relative sense. Since the demonstrative at the beginning of the second clause represented the first clause, and was consequently an attribute of the second, it had to stand in some case, and this case became a conjunction. How closely allied the adverb and the conjunction are may be seen from Greek and Latin, where *quod* or *quoniam* can be used as either the one or the other. Our own *and*, which may be observed, has probably the same root as the Greek loose adverb *καί*, and is originally signified "going further."

Another form of adverb is the infinitive, the adverbial force of which appears clearly in such a phrase as "A wonderful thing to see." Various cases, such as the locative, the dative, or the instrumental, are employed in Vedic Sanskrit in the sense of the infinitive, besides the bare stem or noutar formed by the suffixes *man* and *van*. In Greek the noutar stem and the dative case were alone retained for the purpose. The first is found in infinitives like *δοῦναι* and *φθεῖναι* (for an earlier *φθεπε-φεν*), the second in the infinitives

in *-αι*. Thus the Greek *δοῦναι* answers letter for letter to the Vedic dative *divān*, "to give," and the form *ψευδέναι* is explained by the Vedic *psugdhan*, for *psugdhan*, literally "to do living," *dhan* being the dative of a noun from the root *dhā*, "to place" or "do." When the form *ψευδέναι* had once come into existence, analogy was ready to create such false imitations as *γράφανθαι* or *γραφθένθαι*. The Latin infinitive in *-i* for *-e* has the same origin, *amari*, for instance, being the dative of an old stem *amas* in *per* for *peres* or *peses*, from the same root as our English *be*, the original length of the final syllable is preserved. The suffix in *-um* is an accusative, like the corresponding infinitive of classical Sanskrit. This origin of the infinitive explains the Latin construction of the accusative and infinitive. When the Roman said, "Miseri te ad nihil scribere," all that he meant at first was, "I wonder at you for writing nothing to me," where the infinitive was merely a dative case used adverbially.

The history of the infinitive makes it clear how little distinction must have been felt at the outset between the noun and the verb. Indeed, the growth of the verb was a slow process. There was a time in the history of Aryan speech when it had not as yet risen to the consciousness of the speaker, and in the period when the noun did not possess a plural there was as yet also no verb. The distinction of the first and second personal pronouns, or of suffixes resembling them, to certain stems, was the first stage in the development of the latter. Like the Semitic verb, the Aryan verb seems primarily to have denoted relation only, and to have been attached as an attribute to the subject. The idea of time, however, was soon put into it, and two tenses were created, the one expressing a present or continuous action, the other an aoristic or momentary one. The distinction of sense was symbolized by a distinction of pronunciation, the root syllable of the aorist being an abbreviated form of that of the present. This abbreviation was due to a change in the position of the accent (which was shifted from the stem-syllable to the termination), and this change again was probably occasioned by the prefixing of the so-called augment to the aorist, which survived into historical times only in Sanskrit, Zend, and Greek, and the origin of which is still a mystery. The weight of the first syllable in the aorist further caused the person endings to be shortened, and so two sets of person-endings, usually termed primary and secondary, sprang into existence. By reduplicating the root syllable of the present tense a perfect was formed, but originally no distinction was made between present and perfect, and Greek verbs like *ἔδωκα* and *ἔδωκα* are memorials of a time when the difference between "I am come" and "I have come" was not yet felt. Reduplication was further adapted to the expression of intensity and desire (in the so-called intensive and desiderative forms). By the side of the aorist stood the imperfect, which differed from the aorist so far as outward form was concerned, only in possessing the longer and more original stem of the present. Indeed, as Benfey first saw, the aorist itself was primitively an imperfect, and the distinction between aorist and imperfect is not older than the period when the stem-syllables of certain imperfects were shortened through the influence of the accent, and thus differentiation of forms appropriated to denote a difference between the sense of the aorist and the imperfect which was beginning to be felt. After the analogy of the imperfect, a pluperfect was created out of the perfect by prefixing the augment (of which the Greek *ἐπέμνησεν* is an illustration), though the pluperfect, too, was originally an imperfect formed from the reduplicated present.

Besides time, mood was also expressed by the primitive Aryan verb, recourse being had to symbolization for the purpose. The imperative was represented by the bare stem,

like the vocative, the accent being drawn back to the first syllable, though other modes of denoting it soon came into vogue. Possibility was symbolized by the attachment of the suffix *ya* to the stem, probably by the attachment of *a* and *ā*, and in this way the optative and conjunctive moods first arose. The creation of a future by the help of the suffix *-ya* seems to belong to the same period in the history of the verb. This suffix is probably identical with that used to form a large class of adjectives and genitives (like the Greek *αἰσθητός* for *αἰσθητός*), in this case future time will have been regarded as an attribute of the subject, no distinction being drawn, for instance, between "rising sun" and "the sun will rise." It is possible, however, that the auxiliary verb *as*, "to be," enters into the composition of the future, if so, the future will be the product of the second stage in the development of the Aryan verb when new forms were created by means of composition. The signification of first aorist is in favour of this view, as it certainly belongs to the age of Aryan unity, and may be a compound of the verbal stem with the auxiliary *as*.

After the separation of the Aryan languages, composition was largely employed in the formation of new tenses. Thus in Latin we have perfects like *scripsi* and *amaui*, formed by the help of the auxiliaries *scribo* (*scribo*) and *amo*, while such forms as *amatussum* (*amatus sum*) or *amatus* (*amatus*) have their origin on the other face. So, too, the future in Latin and Old Celtic (*amabo*, Irish *amaim*) is based upon the substantive verb *yo*, "to be," and the English preterite in *ad* goes back to a suffix *did*, the reduplicated perfect of *do*. New tenses and moods, however, were created by the aid of suffixes as well as by the aid of composition, or rather were formed from nouns whose stems terminated in the suffixes in question. Thus in Greek we have aorists and perfects in *-aa*, and the characteristics of the two passive aorists, *ye* and *the*, are more probably the suffixes of nominal stems than the roots of the two verbs *ye*, "to go," and *the*, "to place," as Dapp supposed. How late some of these new formations were may be seen in Greek, where the Homeric poems are still ignorant of the weak future passive, the optative future, and the asperated perfect, and where the strong future passive occurs but once and the desiderative but twice. On the other hand, many of the older tenses were disused and lost. In classical Sanskrit, for instance, of the modal noun forms the presentive and benedictive almost alone remain, while the pluperfect, of which Delbrück has found traces in the Veda, has wholly disappeared.

The passive forms did not exist in the parent Aryan speech. No need for it had arisen, since each sentence as "I am pleased" could be as well represented by "Thy pleasure mine," or "I please myself." It was long before the speaker was able to imagine an action without an object, and when he did so, it was a neuter or substantival rather than a passive verb that he formed. The passive, in fact, grew out of the middle or reflexive, and, except in the two aorists, continued to be represented by the middle in Greek. So, too, in Latin the second person plural is really the middle participle with *estis* understood, and the whole class of dependent or reflexive verbs proves that the characteristics which Latin shares with Celtic could have had at the outset no passive force.

Much light has been thrown on the character and construction of the primitive Aryan sentence by comparative syntax. In contradistinction to Semitic, where the defining word follows that which is defined, the Aryan languages place that which is defined after that which defines it, and Benigne has made it clear that the original order of the sentence was (1) object, (2) verb, and (3) subject. Greater complication of thought and its expression, the connexion of sentences by the aid of conjunctions, and rhetorical inversion caused that dislocation of the original order of the

sentence which reaches its culminating point in the involved periods of Latin literature. Our own language, still remains true, however, to the syntax of the parent Aryan when it sets both adjective and genitive before the nouns which they define. In course of time a distinction came to be made between an attribute used as a more qualitative and an attribute used predicatively, and this distinction was expressed by placing the predicate in opposition to the subject and accordingly after it. The opposition was of itself sufficient to indicate the logical copula, or substantive verb; indeed, the word which afterwards commonly stood for the latter at first signified "evidence," and it was only through the wear and tear of time that a phrase like *Dei bonus est*, "God exists as good," came to mean simply "God is good." It is needless to observe that neither of the two articles was known to the parent Aryan, indeed, the definite article, which is merely a decaying demonstrative pronoun, has not yet been developed in several of the languages of the Aryan family.

We must now glance briefly at the results of a scientific investigation of English grammar and the modification of them which they necessitate in our conception of it. The idea that the free use of speech is tied down by the rules of the grammar must first be given up, all that the grammarian can do is to formulate the current uses of his time, which are determined by habit and custom, and are not bound in a perpetual state of flux. We must next get rid of the notion that English grammar should be modelled after that of ancient Rome, until we do so we shall never understand even the elementary principles upon which it is based. We cannot speak of declensions, since English has no genders except in the pronouns of the third person, and no cases except the genitive and a few faint traces of an old dative. Its verbal conjugation is essentially different from that of an inflexional language like Latin, and cannot be compressed into the same categories. In English the syntax has been enlarged at the expense of the declension; position has taken the place of form. To speak of an adjective "agreeing" with its substantive is as misleading as to speak of a verb "governing" a case. In fact, the distinction between noun and adjective is inapplicable to English grammar, and should be replaced by a distinction between objective and attributive words. In a phrase like "Thou art a canon," *canon* is objective, in a phrase like "a canon-hall," it is attributive, and to call it a substantive in the one case and an adjective in the other, is only to introduce confusion. With the exception of the nominative, the various forms of the noun are all attributive, there is no difference, for example, between "doing a thing" and "doing badly." Apart from the personal and possessive, the accusative of the classical languages can be represented only by position, but if we were to say that a noun is linked only to a verb in the accusative case we should have to declare "king" as an accusative in such sentences as "he became king" or "he is king." In conventional English "it is I" is as correct as "I am I" in French, or "I am I" in Danish, the literary "it is I" is due to the influence of classical grammar. The combination of noun and pronoun and proposition results in a compound attribute. As for the verb, Mr. Sweet has well said that "the really characteristic feature of the English finite verb is its inability to stand alone without a nominal partner." Thus "dream" by itself is a noun, "I dream" is a verb. The place of the nominal prefix may be taken by a noun, though both poetry and vulgar French frequently insert the pronoun even when the noun precedes. The number of inflected verbal forms is but small, being confined to the third person singular and the special forms of the present and past participle, though the latter may with more justice be regarded as belonging to the province of the lexicographer.

ness, the Count de Gramont endeavored to live the life of unostentatious enjoyment. In this he so far succeeded that, although the following century furnished more numerous examples of his kind, he may be taken as the most finished specimen. His ideal man was a being without conscience, without principle, without religion, without a soul. At the court of Charles II he found companions like himself, — women without virtue, men without honour, yet disguised and adorned with courtly manners and that external refinement which did duty for principle, and had it not been that his brother-in-law, Hamilton, conceived the design of writing the memoirs which have made him famous, Gramont would have been as entirely forgotten as most of his friends, save for a brief mention by St. Evremont and another by Bussy Rabutin in that little-visted gallery of portraits, the *Histoire Amoureuse*. His grandfather had the distinction of being husband to Diane d'Andouins, *la belle Corisande*, one of the mistresses of Henry IV. The grand-on always regretted that the king had not acknowledged his father for his own son, lamenting even in the presence of Louis XIV that his family had missed the chance of becoming, in this illegitimate fashion, a branch of the royal line. The anecdote is entirely characteristic. It was at first proposed to enter him in the church, but he speedily perceived that his vocation was not ecclesiastical, and joined the army, in which he saw a great deal of active service, and was rewarded with the governorship of the Pays d'Aunis, and with other small posts. He crossed over to England during the protectorate of Cromwell. In the year 1662, two years after the restoration of Charles II, he was ordered from the French court and again repaired to London, where he found such a welcome as was due to his manners, his gaiety, his extraordinary good spirits, and his love of gambling, intrigue, gallantry, and pleasure. It is the period of his residence at the English court which forms the greater part of Hamilton's memoirs. He is described by Bussy Rabutin as having "laughing eyes, a well formed nose, a pretty mouth, a little dimple in the chin which gave an agreeable effect to the whole face, a certain finesse in his countenance, and a fairly good statue but for a stoop." In the whole English court there was no one more full of wit, more avid of pleasure, more devoid of all moral restraint, not even Rochester himself, than the Count de Gramont. Naturally, the court being what it was, there was no one more popular. In a court where the women vied with each other for the king's favour, where the men mutually choiced at play, seduced their friends' wives, and corrupted their friends' daughters, that man would be most popular in whom the absence of principle became, by reason of his grace, *esprit*, and elegance, in itself a recommendation. Gramont was as purely a sensualist as any Roman of the later empire.

He married, in London, but on compulsion, the sister of his future biographer, Miss Hamilton, who, her brother tells us, in the memoirs, was able to fix his affections. The statement must be received with some qualifications. The count, it is true, was by no means young when he married. At the same time, he "galantized" for many years afterwards, and, in fact, to the very end of a long life. He was the only old man, says Ninon de l'Enclos, who could affect the follies of youth without being ridiculous. In fact, Gramont, like La Fontaine, was a spoiled child, to whom everything was allowed, and who repaid indulgence by perpetual high spirits, and a continual flow of wit and *bona mots*. At the age of seventy-five he had a dangerous illness, during which he became reconciled, in his way, to the church, but on recovery relapsed into his old habits. At eighty he either dictated or revised his own memoirs, written by his brother-in-law Antony Hamilton. When they were finished he sold

the manuscript for 1500 livres and kept most of the money himself. Fontenelle, then editor of the press, refused to purchase the work, from considerations of respect to the old man who had so strangely exposed in its pages the whole of his character. These scruples were overcome by the count himself, who had the pleasure of seeing his biography appear in his own lifetime, and of laughing with the rest of the world at his own rogueries at cards, his amorous adventures, and his secret intrigues.

He died at the great age of eighty-six. His biography, Hamilton died thirteen years later at the age of seventy-four. The memoirs of the Count de Gramont are not to be recommended for general reading, yet they have the merit of being true, in no other work is the reality of that profligate society of St. James's so vividly expressed, in no other contemporary memoirs is there so much wit, such grace of style, such skill in portraiture. Numerous editions and translations have been issued of this work, whose popularity seems destined to continue and grow.

GRAMPUS (*Orca gladiator*, Lacep.), a cetacean belonging to the *Delphinidae* or dolphin family, and characterized by its rounded head without distinct beak, its high dorsal fin, and its large conical permanent teeth. Its upper part is of a nearly uniform glossy black color, and the under part white, with a stripe of the same color over the eye. The name "grampus" is derived from the French *grand poisson*, though the Norman *grayot*. It is also known as the "killer," in allusion to its ferocity in attacking its prey, which consists largely of seals, porpoises, and the smaller species of dolphins. Its swiftness is only equalled by its voracity, which is such that in a specimen measuring 21 feet in length, dissected by Professor Schmidt, the remains of fourteen seals and thirteen porpoises were found, while the animal appeared to have been choked in the endeavor to swallow another seal, the skin of which was found entangled in its teeth. They also pursue and commit great havoc among the bully-bul and gentle whales of white whale, which sometimes throw themselves ashore in order to escape from their remorseless persecutors. The grampus is an inhabitant of northern seas, occurring on the shores of Greenland, and having been caught, although rarely, as far south as the Mediterranean. It is not common, although there are numerous instances of its capture, on the British coasts. The latest of these occurred in March 1879, about a mile to the west of Stanton, on the Firth of Forth. The creature on being dragged ashore, while still alive, was said by the onlookers to have given forth shrill piercing cries somewhat resembling in their sharpness a woman's voice. The specimen was an adult male, and measured 21 feet 10 inches along the curve of the back, with a girth of 13 feet. It had 24 teeth in each jaw, the front tooth on each side of the lower jaw being exceedingly small and almost hidden by the overlapping of the gum, while the two immediately succeeding ones on each side were worn down almost to the level of the gum. A striking feature in the grampus is the high dorsal fin, which in the specimen mentioned measured within 2 inches of 1 foot in height.

GRAN (the ancient *Trisopranum*, whence Hingmangan, *Estergom*, and Latin *Strigomum*), the capital of a county of the same name, seat of the prince primate, and formerly a royal free city, is situated on the right bank of the Danube, nearly opposite the confluence of the Larn (Lain), 35 miles north-west of Buda, 17° 46' N. lat., 18 41' E. long. It may be generally divided into the town proper, the episcopal quarter also called Virvaros (Wettersburg), and the communes of St. Thomas and of St. George. The finest terraces and public buildings are to be found in the two first-named portions of the town. On an elevated and commanding position, where once a fortress stood, are the

seminary and theological institute for the education of priests, the residences of the chapter, and the basilica. This cathedral, commenced in 1821, consecrated in 1856, and completed in 1870, is built after the model of St. Peter's at Rome, and is one of the finest churches in Hungary. Among the other public edifices and educational establishments, besides several churches and two monastic houses, are the archiepiscopal residences, the county and town halls, a training school for teachers, an upper gymnasium, a hospital, a library, a savings bank, &c. The population in 1870 was 8780, chiefly employed in cloth-weaving, wine-making, and agricultural pursuits. There is connexion with the market town of Paketzay on the left bank of the Danube by means of a bridge of boats.

Gian is one of the oldest towns of Hungary, and is famous as the birthplace of St. Stephen, the first prince crowned "apostolic king" of Hungary. During the early times of the Hungarian monarchy it was the most important metropolitan centre in the country, and it was the meeting place of the diets of 1016, 1111, 1114, and 1246. It was almost completely destroyed by Tatar hordes in 1241, but was rebuilt and fortified by king Bela IV. In 1683 it fell into the hands of the Turks, from whom it was recovered, in 1693, by Carl von Munkács. In 1693 it reverted to the Turks, who held it till 1683, when it was regained by the united forces of John Sobieski, king of Poland, and Prince Christian of Lorraine. In 1708 it was destroyed by the city of Joseph I. On the 18th April 1818 it was partly destroyed by fire. Gian lay in the direct line of the victorious revolutionary campaign of April 1849. Since 1876 its civil privileges have been of a corporate character.

GRANADA, a modern province of Spain, consisting of the central portion of the old kingdom of the same name, is bounded on the N and NE by Jaen, Albacete, and Murcia, on the E by Almeria, on the S by the Mediterranean, and on the W by Malaga and Cordova, having an area of 4937 English square miles and an estimated population (1870) of 483,346. It includes, and indeed chiefly consists of, the western and northern portion of the Sierra Nevada, which in the peaks Coto de Mulhacen and Picacho de la Velez, overlooking the town of Granada, attains the heights of 11,781 and 11,607 feet respectively. From the central chain of this Sierra all the principal rivers of the province take their rise—the Guadalmquivir which, flowing past Guadix, in a northerly direction, falls into the Guadalquivir in the neighbourhood of Ubeda, the Genil which, after traversing the vega of Granada, leaves the province a little to the westward of Loja, and joins the Guadalquivir between Cordova and Seville, and the Rio Grande which falls into the Mediterranean at Motril. The climate in the lower valleys and the narrow fringe along the coast is warm, but on the higher grounds of the interior is somewhat severe, and the vegetation varies accordingly from the subalpine to the alpine. The soil of the plains is very productive, and that of the vega of Granada is considered the richest in the whole peninsula. From the days of the Moors it has been subjected to most careful and systematic irrigation, and it continues to yield in great abundance and in good quality wheat, barley, maize, wine, oil, sugar, flax, cotton, silk, and almost every variety of fruit. There are productive mines of lead, silver, copper, zinc, and manganese, which in 1866 gave employment to 1099 persons, mining indeed, with various agricultural and horticultural operations, including bee-farming, constitutes the staple industry of the province. In the mountains immediately surrounding the city of Granada occur many kinds of alabaster, some of which are very fine, there are also quantities of jasper and other precious stones in considerable variety. Mineral waters are chiefly sulphate and sulphurous, are abundant, the most important springs being those of Alhama, which have a temperature of 118° Fahr. The chief centres of population are, besides Granada, the capital, Motril, Alhama, Loja, Guadix, and Huescar. Apart from the great highways traversing the province, which are ex-

cellent, the means of communication are few, and on the whole bad. The only railway is that which connects Granada with Bobadilla on the Malaga and Cordova line.

During the Roman period, Granada, from the time of Augustus formed an undisturbed portion of the province of Bætica, of which the four *conventus judicis* were Cadix, Cordova, Bæta, and Seville. Along with the rest of Andalusia, it is a result of the great invasion from the north in the 5th century, it fell to the lot of the Vandals. Under the empire of Cordova, one side from the 8th century, the town of Granada rapidly gained in importance, and ultimately became the seat of a provincial government, which, after the fall of the Ommyades (1038), ruled with Seville, Jaen, and others as an independent principality. By the conquests of St. Ferdinand in the first half of the 13th century, Granada was left the sole representative of the Mohammedan power in Spain, and even it was compelled to pay tribute to the sovereigns of Castile. The limits of the kingdom at that time were nearly identical with those of the province prior to 1893, the modern provinces of Malaga and Almeria being until that date included. It is said to have contained a population of 3,000,000, and to have had considerable commerce, especially with Italy in silk. On the expulsion of Boabdil in January 1492, Granada was united to the crown of Castile, but with special privileges which were afterwards successively withdrawn.

GRANADA, the capital of the above province, is situated at the confluence of the Darro and the Genil, not far from the base of the Sierra Nevada (37° 13' N lat., 3° 41' W long). Difficult suggestions have been made as to the etymology of the name, which is rather obscure,—the least

Plan of Granada

probable being that it is derived from *granada*, "a pomegranate," in allusion to the abundance of pomegranate trees in its neighbourhood. The Moors called it *Karnathah* or *Karnathah-al-Yahoud*, and possibly the name is composed of the Arabic words *luwn*, "a hill," and *nathah*, "stranger"—the "city" or "hill of strangers." Granada is built

partly on level ground near the Genil and partly on the slopes of two adjacent hills, at an elevation of about 3300 feet above the sea. The more ancient quarters of the town still retain much of the Moorish style, but the modern part is somewhat commonplace. It contains several squares, of which the most remarkable is the *Ibora* square, where four fountains were formerly held. There is also a beautiful shady walk, called the *Alameda*, which is one of the most frequented promenades. The old city comprises the faubourgs of *Antequera*, *Alcazaba*, *Alhambra*, and *Albarrin*, the last being named after the settlers who came from *Doria*, after the capture of that city by St Ferdinand. For a detailed account of the *Alhambra* the reader is referred to the special article, vol. i p. 670. The *Antequera* and *Albarrin* are mostly inhabited by the working classes. In the cemetery of the latter there are still a few ruins of an ancient mosque. The town proper contains a great number of churches and other public edifices. The cathedral, a somewhat heavy and irregular building, was begun in 1529 by Diego de Siles, and finished in 1639. It is profusely ornamented with jaspe and coloured marble and surmounted by a dome, and it contains several valuable paintings by Alonso Cano, portraits of Ferdinand and Isabella by Buncon, and marble statues of several kings and queens of Spain. In one of its numerous chapels (the *Chapel Royal*) are buried three "Catholic Majesties," and Philip and Juana. The church of *Nuestra Señora de las Angustias* has a splendid high altar and fine ceiling. That of St José is an elegant modern building. Other remarkable edifices are the monastery of St Gerónimo, founded by Gonzalo de Cordova, who is buried there, the *Cartusian* convent (*Cartuja*) adorned with paintings by Murillo, Morales, and Cano, the university, founded in 1531 by Charles V, and the library. Granada is the birthplace of many eminent writers and artists, both Mahometan and Christian, among the latter may be mentioned Fray Luis de Granada (1505), Hurtado de Mendoza (1505), the historian of the war of Granada, Alonso Cano (1601), the great painter, and Moya (1610), who was both painter and sculptor. The climate of the town is pleasant and healthy, especially during the spring and summer months. Its manufactures are unimportant, the chief being coarse woollen stuffs, hats, paper, soap, and gunpowder. Silk-weaving was once extensively carried on, and large quantities of silk were exported to Italy, France, Germany, and even America, but the production now is very limited. The education of the lower classes is much neglected, the city having only a few insignificant schools. In the year 1878 the population amounted to about 75,000.

The history of Granada does not go back far, at all, into the Roman period (for it is not to be confounded with the ancient *Iliberris*), and even under the Moors it held a place of very subordinate importance until the period of the conquest of St Ferdinand, when it became the extreme seat of Islam in Spain, and rose to almost unparalleled splendor under Mohammed bin Alahamm, the builder of the *Alhambra*. It is said in its best days to have had 400,000 inhabitants, 70,000 houses, and 60,000 warriors, but this is probably an exaggeration. In the 15th century it was the last stronghold of the Moors, against the Christian forces under Ferdinand and Isabella, and after a long siege it was surrendered by Boabdil on 24 January 1492. From that time Granada's wealth and magnificence rapidly decreased till 1610, when the Moors were expelled from Spain.

GRANADA, a city of Central America, state of Nicaragua, is situated on the N W bank of the Lake of Nicaragua, 30 miles N N W of the town of that name. The suburbs are composed of cane huts, occupied by the poorer inhabitants, but the city proper is formed of one storied houses built of adobe or sun dried bricks, roofed with tiles. They have balconied windows, and are surrounded by courtyards with ornamental gateways. It possesses several old churches and the remains of ancient fortifications. By

means of the lake and the river San Juan, it communicates with the Caribbean Sea, and carries on a considerable trade in cocoa, cochineal, indigo, and hides. The steamer "Cobang" in the end of 1878, after several unsuccessful attempts, forced a passage up the river San Juan from the sea to Lake Nicaragua, thus establishing steam navigation between Granada, the Bay of San Viego, San George, and other towns, and direct communication between Chigton and Granada. The feat is of importance in view of the project of constructing an oceanic canal by this route.

Granada was founded by Juan de Tamariz de Cordova in 1529, and he erected a fort for its protection. At an early period it surpassed Leon in importance, and was one of the richest cities in North America. It suffered greatly from the attacks of pirates in the latter half of the 17th century, and in 1666 was completely sacked by them. In 1865 it was taken by the filibuster William Walker, and partially destroyed by fire, and though retaken in 1867 it has never recovered its former prosperity, a great part of it being still in ruins. The population was then 16,000.

GRANADA, Luis de (1604-1688), a Spanish preacher and ascetic writer, was born of poor parents at Granada in 1604. At five years of age he was left an orphan, but the Conde de Tendilla, alcaide of Alhambra, having accidentally observed his singular intelligence, took him under his protection and had him educated with his own sons. At the age of nineteen he entered the Dominican convent of Santa Cruz, Granada, whence he went to the college of St Gregory, Valladolid. After completing his theological education he was named prior of the convent of Santa Cruz, where he excoriated his preaching gifts under the direction of the celebrated orator Juan de Avila, whom he subsequently rivalled, if he did not surpass him, in eloquence. Having been invited by Cardinal Henry, infante of Portugal and archbishop of Evora, to Badajoz in 1655, he founded a monastery there, and two years later was elected provincial of Portugal. He was also appointed confessor and counsellor to the queen regent, but he declined promotion to the archbishopric of Braga, and on the expiry of his provincial office in 1661 he retired to a Dominican convent at Lisbon, where he died in 1688. Luis de Granada enjoyed the reputation of being the first ascetical author of his day, and his description of the "devout into hell" is one of the finest specimens of eloquence in the Spanish language. He also acquired great fame as a mystic writer, his *Guia de Penitentes*, or *Guide to Sinners*, first published in 1556, being still a favourite book of devotion in Spain, and having been translated into nearly every European language.

His principal other works are *Libro de la Oracion y Meditacion*, Salamanca, 1667; *Introduccion al simbolo de la Fe*, Salamanca, 1589; *Relaciones Escritas*, viz. *con el conde de Tendilla*, 1655; *Lisbon*, 1678; *Siempre loco un conuenciente conuente* (his own confession of sins necessary to him), and several volumes of sermons. A collected edition of the works of Luis de Granada was published by Pinta at Antwerp, in 1572, at the expense of the duke of Br., and by Luis Maldonado, Madrid, in 1667, afterwards reprinted at various periods. See preface to this edition of his works, *prefacio a la obra de Penitentes*, Madrid, 1781; *Relaciones de Indias*, 1.º p. 100, vii, viii, 2.º; *Tucker's History of Spanish Literature*, and *Pug Dutt's Hist. de la litt. espagnole*, Paris, 1864.

GRANADILLA, the name applied to *Lasiacantha grandis* var. *Linn.*, a plant of the natural order *Passifloraceae*, a native of tropical America, having smooth, cordate, ovate, or acuminate leaves, petioles bearing from 4 to 6 glands, an emetic and narcotic root, acented flowers, and a large, oblong fruit, containing numerous seeds, imbedded in a subacid edible pulp. The granadilla is sometimes grown in British hot-houses. The fruits of several other species of *Passiflora* are eaten. *P. lamellata* is the "water melon," and *P. malinica* has the "sweet calabash" of the West Indies.

GRAN CILACAO, an extensive region in the heart of South America, which stretches from 26° to 29° N lat., and belongs partly to Bolivia and partly to the Argentine Republic, the boundary between the two states coinciding

by M. Constahtia, a landscape painter of some reputation who lived in the town. In 1793 Gianet followed the volunteers of Aix to the siege of Toulon, at the close of which he obtained employment as a draughtsman in the arsenal. Whilst yet a lad he had, at Aix, made the acquaintance of the young Comte de Forbin, and it was upon his invitation that Gianet, in the course of the year 1797, proceeded to Paris. De Forbin was one of the pupils of David, and Gianet entered the same studio. Later on he got possession of a cell in the convent of Capuchins, which, having served for a manufactory of assignats during the Revolution, was afterwards inhabited almost exclusively by artists. In the changing lights and shadows of the corridors of the Capuchins, Gianet found the materials for that picture to the painting of which, with varying success, he devoted his life. In 1802 he left Paris for Rome, where he remained until 1819, when he returned to Paris, bringing with him besides various other works one of fourteen repetitions of his celebrated *Christus des Capucins*, executed in 1811. The figures of the monks celebrating mass are taken in this subject as a substantive part of the architectural effect, and this is the case with all Grant's work, even with those in which the figure subject would seem to assert its importance, and its historical or romantic interest. Stella painting a Madonna on his Prison Wall, 1810 (Leuchtenberg collection), *Soriana a l'Hopital*, 1816 (Louvre), *Basilique basse de St François d'Assise*, 1823 (Louvre), *Rachet de l'Ordre des Carmes*, 1831 (Louvre), *Mort de Foucault*, 1834 (Villa Maubert, 1831 (Louvre), are among his principal works, all are marked by the same peculiarities, everything is sacrificed to tone. In 1819 Louis Philippe decorated Gianet, and afterwards named him Chevalier de l'Ordre St Michel, and Conservateur des tableaux de Versailles (1826). He became member of the Institute in 1830, but in spite of these honours, and the ties which bound him to M. de Forbin, that director of the Louvre, Grant constantly returned to Rome. After 1848, he retired to Aix, immediately lost his wife, and died himself on the 21st November 1849. He bequeathed to his native town the greater part of his fortune and all his collections, these are now exhibited in the Musée, together with a very fine portrait of the donor painted by Ingres in 1811. M. Deloche, in *Louis David et son temps*, devotes a few pages to Gianet and his friend the Comte de Forbin.

GRANITE, a rock so named from the Latin *granum*, a grain, in allusion to the granular texture of many of its varieties. The term appears to have been introduced by the early Italian antiquaries, and it is believed that the first recorded use of the word occurs in a description of Rome by Flaminio Vacca, an Italian sculptor of the 16th century. This description was published by Montfaucon in his *Dierum Italicum*, where we read of certain columns "ex marmore granito Aegyptio" (cap. xvi), and of others "ex marmore granito Aethiops marmore" (cap. xvii), showing that the Romans of Vacca's day were acquainted with granite from Egypt and from Ethio. Granite is also referred to by Ctesiphon in his treatise *De Metallis* (1696), and by Tournefort in his *Rélation d'un Voyage au Levant* (1698), indeed the latter has been cited by Emmeisler (*Lehrb. d. Miner.*) as the first author who uses the term. By these early writers, however, the name was loosely applied to several distinct kinds of granular rock, and it remained for Werner to give it that precise meaning which it at present possesses as the specific designation of a rock.

Granite is a crystalline-granular rock consisting, in its typical varieties, of orthoclase, quartz, and mica, to which a plagioclase felspar is usually added. These minerals are aggregated together without the presence of any matrix or connecting medium. Thin sections of a true granite, examined under the microscope by transmitted light, show

no traces of any amorphous or crypto-crystalline ground-mass. The chemical composition of the rock will, of course, vary with its mineralogical constitution. For an average analysis see *Geology*, vol. x, p. 233. The proportion of silica varies from 62 to 81 per cent. Granite belongs, therefore, to Bunsen's class of acid rocks, or those which contain more than 60 per cent of silica. Dr Haughton has found an exceptionally low proportion of this oxide in some of the Irish granites (58.41 per cent, e.g., in "some Donegal granites," *Quart. Journ. Geol. Soc.*, xviii, 1862, p. 108). The specific gravity of granite varies from 2.69 to 2.73.

Orthoclase, or potash felspar, is the principal constituent of most granites. This mineral occurs either in simple crystals, or in twins formed on what is known as the "Carlsbad type," such crystals being common at Carlsbad in Bohemia. In porphyritic granites, such as those of Cornwall and Devon, the orthoclase crystals may attain to a length of several inches, and the twinning is marked on the fractured crystals by a line running longitudinally down the middle, and dividing the crystal into two halves. In colour the orthoclase generally varies between snow white and flesh-red. The green felspar known as Anorthoclase, which occurs in certain granites, has lately been shown by De la Senozon to belong to the species *Androsalix*, and not, as previously supposed, to orthoclase (*Ann. d. Ch. Phys.*, vi, 1876, p. 433). The plagioclase, another, or tinctive felspar, of granite occurs in crystals which are generally smaller than those of the orthoclase, and which exhibit, even to the naked eye, their characteristic twin striation. Moreover, the lustre is frequently resinous or lustrous, whilst that of the orthoclase is pearly on the cleavage surfaces. In most cases the plagioclase is the sodalium felspar (called *albite*), but in some granites it is *albite* or *sodalite* felspar, as shown by Haughton in many of the Irish and Cornish granites (*Proc. Roy. Soc.*, viii, 1869, p. 209). When a granite becomes weathered, the felspar may decompose into *kaolin* or *china clay*, the commonest cause of this alteration is indicated under the microscope by the fineness of the felspar, by the ill defined edges of the crystals, and in the case of plagioclase by disappearance of the characteristic striae.

The quartz of granite occurs generally in irregularly-shaped angular grains, but occasionally in distinct crystals which are double hexagonal pyramids with or without the corresponding prism. Colourless quartz is most common, but grey, brown, or bluish varieties also occur. Whatever its colour, it is as a rule transparent in microscopic sections, though sometimes rendered milky by the presence of a vast number of minute cavities containing liquid (see *Geology*, vi, 1876, p. 433), and for Sobhy's original remarks see *Quart. Journ. Geol. Soc.*, xiv, p. 459). In many granites the quartz fills up the spaces between the crystals of felspar and of mica, and receives impressions from these minerals. This fact has been advanced against the view that granite is a state of fusion, since it is assumed that, as the quartz is the most infusible of the three component minerals, it would have been the first to solidify on the cooling of the magma, whereas the relation of the quartz to the associated minerals in most cases shows that it must have solidified after the crystallization of the felspar and mica. In some granites, however, the quartz is developed in free crystals, thus pointing to an early solidification of this mineral. The mica, which is usually the least abundant constituent of the granite, occurs in thin scales of angular shape or in hexagonal plates. It is either a white bluish or pinkish mica (*leucocaine*), or a dark-brown or greenish mica, generally unusual (*biotite*). Both species may occur in the same granite. Haughton has shown that some of the white mica of the Cornish granites is *lepidolite*, or lithia mica, while some of the black mica in the same rocks is the iron-

potash mica, *lepidomelane* (*Proc. Roy. Soc.*, xvii p. 309). Professor Heddle finds that the black mica of most Scottish granites is a distinct species, which he calls *laughlontite* (*Mineralog. Mag.*, No. 13, 1879, p. 72). A large number of accessory minerals occur in granite, no fewer than forty-four being cited by Zirkel (*Lehrb. d. Petrog.*, i p. 481). Upon the presence of these supplementary minerals numerous varieties of granite have been founded. Thus, if tourmaline be present, the rock is a *schistaceous* or *tourmaline granite*, when cassiterite or tin-stone occurs, it forms a *stanniferous granite*, the presence of epidote gives rise to an *epidote granite*, and so on with other minerals. The most common accessory constituent of granite is hornblende, a mineral which appears to replace to some extent the mica, and thus produces a *hornblende* or *syenite granite*. This rock was formerly, and by some petrographers is still, termed *syenite*, it is the *syenite* of Pliny, so named from Syene in Upper Egypt, where a similar rock was quarried by the ancient Egyptians. By modern petrographers, however, the term *syenite* is usually restricted to a rock which is an aggregate of orthoclase and hornblende,—in other words, a granite in which the quartz has disappeared while the mica has been superseded by hornblende. A beautiful schistaceous rock, which is apparently a variety of granite, has been described by Pring under the name of *tschukwente* (*Comptes Rendus*, lxx, 1861, p. 913). It occurs in the parish of Invallian, near Lostwithial, in Cornwall, where it is found in the form of boulders, but has not been detected *in situ*. This rock is composed of tourmaline, or scholite, with quartz and orthoclase, the last named mineral occurring in large flesh coloured crystals, which by contrast with the dark blue produce a very beautiful effect. Two varieties of tourmaline, one brown and the other bluish, have been detected by Professor Bonney (*Mineralog. Mag.*, No. 1, 1877, p. 210). The outcrops of the lake of Wallington, in St. Paul's Cathedral, is wrought out of a syenoid block of Invallianite. Many varieties of granite are founded upon structural characteristics. Occasionally the constituents are developed in such large individuals as to form a *giant granite*. Crystals of orthoclase, associated with quartz in a peculiar parallel arrangement, produce the variety known as *glauber granite* or *Lapis Judaeus*—names which refer to the resemblance which the rock presents, when cut in certain directions, to lines of Hebrew characters. Graphite granite was termed by Havy *pegmatite*, but this name is now generally applied to a coarse admixture of orthoclase, quartz, and silvery mica. When any of the component minerals occur in large crystals, unbedded in a fine grained base, a *porphyritic granite* is produced. Generally the crystals are those of orthoclase, as in many of the West of England granites, and in the characteristic rock of Shap Fell in Westmoreland. *Grauwacke* is a name applied to a variety of granite made up of orthoclase and quartz, with more or less plagioclase and a small proportion of mica. A granite composed of only felspar and quartz is called *happite* or *semi-granite*. Some of the micaceous varieties are known as *granulite*. When, instead of the mica disappearing, the felspar is absent, the resulting aggregate of quartz and mica is termed *gessen*, it is frequently a tin-bearing rock. Occasionally the granite, when fine in grain, loses its mica, and an infusible mixture of orthoclase and quartz is thus obtained, such a rock is known as a *feldstone*. Crystals of orthoclase disseminated through a felsitic matrix, either compact or microcrystalline, give rise to a *felspar porphyry*, while crystals or rounded grains of quartz in a similar felsitic base produce a *quartz-porphyry* or *quartz-feldite*. By Cornish miners these quartz-porphyrates are termed *clavans* (*clavante* of Jukes), but this name is also applied to fine grained granites and to almost any rock which occurs as a dyke running through the hills or clay slate

Few questions have been more warmly discussed than the origin of granite. When this rock is found forcing its way through older rocks, and appearing at the surface in large bosses from which veins are sent forth in all directions, there can be little doubt of its eruptive character. The small width of some of these granitic veins, or apophyses, suggests that the rock must have existed in a condition of perfect fusion or complete liquidity, and not simply as a viscous paste, before it could have been injected into such narrow fissures as those which are now occupied by granite. In many cases, the rocks which are penetrated by the granitic veins are altered in such a manner as to indicate a considerable elevation of temperature; limestone in the neighbourhood of the veins may become anorthoidal, and shales may become indurated or even converted into hornstone, while new minerals are often developed in the vicinity of the intruded veins. In these veins the granite is apt to change its mineralogical constitution, becoming either fine-grained or felsitic, or even reduced at the extremities of the vein to quartz. From the days of Hutton it has been generally admitted that most granite is of igneous origin. Since it appears to have been solidified at great depths beneath the surface, it has been distinguished as a *plutonic* rock, while those eruptive rocks which have risen to the surface, and have there consolidated, are termed *volcanic* rocks. The older geologists regarded granite as the primitive rock of the earth's crust, forming the floor of all stratified deposits and the nucleus of mountain chains. Such a view, however, has been long exploded. It is known indeed that granite, so far from being in all cases an original rock, may be of almost any geological age. Some is undoubtedly as old as the Silurian period, while other granites are certainly as young as the Tertiary rocks, and perhaps of even more recent date. By many field-geologists granite has of late years been regarded as a metamorphic rather than as a truly igneous rock. Metamorphism, however, is a term which has been so vaguely used that most of our eruptive rocks may, in a certain sense, be said to be metamorphic. Still, in the case of granite, it has often been pointed out that a passage may be traced from this rock into gneiss, and that gneiss itself may be regarded as an altered sedimentary rock. This so experienced an observer as Professor Ramsay expresses his opinion that "granite is sometimes merely gneiss still further metamorphosed by heat in the presence of moisture" (*Atlas Geol. de Gr. Brit.*, 5 ed., 1876, p. 42). For a number of years it has been a question whether granite can pass into gneissose rocks, and these in turn, by numerous gradations, into undoubted stratified deposits, see Green's *Geology*, part 1 p. 307, and also Gossology, vol. x, p. 309.

Chemists have also brought forward arguments against the igneous origin of granite. Thus it has been argued that the specific gravity of the quartz of granite is about 2.6, while that of silica after fusion is only 2.2. It must be remembered, however, that the quartz of granite has solidified under great pressure, as proved by Mr. Schott's observations, and it is probable that such pressure would increase the density of the silica. Moreover, it has been pointed out by the late Dr. Forbes (*Geol. Mag.*, iv, No. 10, 1887, p. 443) that the siliceous tests of certain infusoria, which assuredly have not been fused, are as low as 2.2. Another argument which has been advanced against the igneous origin of granitic rocks is based on the fact that they contain minerals of a basic character which could not have existed in a state of fusion in the presence of free silica, without forming a combination with the latter. Again, some of the accessory minerals in granite would suffer change by an elevation of temperature, while many of them contain water which, it is assumed, would be expelled on fusion. Probably, however, these minerals are in most

cases of secondary origin, and have been produced by the alteration of the granite. The mere presence of water is not incompatible with a pyrognostic origin, and Pabst has asserted (*op cit*) that specimens of lava, taken from a current on Etna while the lava was still flowing, contained crystals of stibite, a mineral containing 16 per cent of water. Mr Sorby has shown, too, that the quartz of volcanic rocks contains microscopic cavities enclosing liquid. It appears, indeed, that in the fusion of all eruptive rocks water has played a very important part. Dr Haughton has sought to reconcile the opposing views as to the origin of granite by admitting what he calls a *hydiometamorphic* origin for this rock. He believes that the rock, having been poured into veins and dykes when in a state of fusion, was subsequently altered by the action of water at temperatures which, though high, were insufficient for the fusion of the granite (*On the Origin of Granite as Addressed to the Geol. Soc. of Dublin*, 1863).

Granite rocks are extensively used for constructive and decorative purposes, though their industrial applications are necessarily restricted by the expense of working so hard a material. Although some granites are apt to decompose on exposure to atmospheric influences, the felspar passing into china-clay, other varieties are remarkable for their extreme durability, as attested by the monuments of ancient Egypt, on which the incised hieroglyphics still retain their sharpness. It appears that in England granite was not brought into extensive use much before the beginning of the present century (Cressy). It is now largely employed for massive structures, such as bridges and sea-walls, as also for kerbs and paving-stones. The best known granites are the grey variety from Aberdeen and the red granite of Peterhead, 30 miles north of Aberdeen. The granite of Dartmoor in Devonshire, and of the huge bosses which protrude through the clay slates of Cornwall, are largely worked as building and ornamental stones (for description of these granites see Sir H. T. de la Beche's *Report on the Geol. of Cornwall and Devon*). In Ireland there is much fine granite, which is quarried to a limited extent,—the Castle-wellan granite having been used in the Albert Memorial in Hyde Park (Hill's *Building and Ornamental Stones*, 1872). The hornblende varieties of granite are remarkably tough, and are largely employed for road metal. For this purpose great quantities are quarried in the Channel Islands. Red granite occurs in abundance on the coasts of Maine, U.S., as well as in New Brunswick, and grey granite at Quincy and elsewhere in Massachusetts. Granite is frequently polished when used for monumental and decorative purposes. The polishing is effected by an iron tool, worked first with sand and water, then with emery, and lastly with putty powder or oxide of tin, when the emery and putty are used, a surface of flannel is interposed between the granite and the iron tool ("On Granite Working," by Geo. W. Mun, *Journal Soc. Arts*, xiv, 1866, p. 470).

As an element of scenery granite generally forms rounded hills, scantly clad with vegetation, but it sometimes rises into sharp pinnacles, as in the *arêtes* of the Alps. By denudation the rock may break up into cuboidal blocks, which often remain piled upon each other, forming the characteristic "tors" of Cornwall and Devon. Hills of granite are frequently surmounted by masses of weathered rock of spheroidal form, such as the Cornish looking-stones or logan stones. The weathering of granite often produces boulder-shaped masses in such numbers as to form, around the summit of the hill, a "sea of rocks" (*Telegraph*).

Zirkel, 2 vols., Bonn, 1866, *Elemente der Petrographie*, by Von Lasaulx, Bonn, 1875, *Cotté's Ideology*, translated by P. H. Lawrence, 2d ed., London, 1876, *The Study of Rocks*, by F. Rutley, London, 1879, and the numerous contributions by the

Rev. Prof. Haughton in *Proc. Irish Acad.*, and *Quart. Journ. Geol. Soc. Lond.* For chemical composition of Cleophris's Needle, by G. W. Wiggins, see the *Analyte*, 1878, p. 382. (F. W. R.)

GRANMICHELLE, or GRAMSCETTA, a market town of Sicily, in the province of Catania, about 8 miles from Catagone on the road to Catania. It lies on the side of a hill, the summit of which is crowned by a castle which, along with the town itself, was formerly a fief of the Brancatelli Buteia family. Beautiful marble is found in the vicinity, and the inhabitants, who in 1871 numbered 10,058, trade in oil.

GRANSON, GRANDSON, or GRANDSEY, a small town in Switzerland, canton of Vaud, is situated near the southwestern extremity of the Lake of Neuchâtel. It possesses the ruins of an old castle, containing a collection of antiquities, and has a very ancient church, once connected with a Benedictine abbey, with a number of pie Christian images. The town is of Roman origin. It was captured in 1475 by the Edgenosen, and taken in the following year by Charles the Bold, but in March of that year the Edgenosen again defeated him near Granson with great slaughter. From that time till 1803 it was one of their lordships. The site of the battle is marked by three great blocks of marble. The population of the town in 1870 was 1587.

GRANT, Mrs ANN (1755-1838), a Scottish authoress, generally known as Miss Grant of Laggan, was born at Glasgow, 21st February 1755. Her father, Duncan MacVicar, who held a commission in the army, in 1757 with his regiment to America, and his family followed him in 1758. He received an allotment of land on returning from the army in 1765, but ill health compelled him to return to Scotland in 1768, and after the outbreak of the revolutionary war his lands were confiscated. In 1779 Anne married the Rev. Mr Grant of Laggan, near Fort Augustus, Inverness, and on his death in 1801 she was left with a large family and only a very small income. It being known to several of her friends that she occasionally wrote verses, a proposal was made that she should publish a volume of poems, and this being acceded to, the names of as many as 3000 subscribers were obtained. The volume appeared in 1803 under the title of *Original Poems, with some Translations from the Greeks, and met with a rather favourable reception*, on account of its easy versification and the truth and tenderness of the sentiment of some of its smaller pieces. In 1806 she published *Letters from the Mountains, being a Selection from the Author's Correspondence with her Intimate Friends from 1773 to 1804*, which, by its spirited descriptions of Highland scenery, character, and legends, awakened a large amount of interest. Her other works are *Memoirs of an American Lady, with Sketches of Manners and Scenery in America as they existed previous to the Revolution* (1808), containing reminiscences of her stay with Miss Schuyler, the lady with whom she spent four years of her childhood in America, *Essays on the Superstitions of the Highlanders of Scotland* (1811), and *Eighteen Grandees and their Poets*, or *Poems* (1814). After the death of her husband, Miss Grant resided for some time on a small farm near Laggan, but in 1803 she removed to Woodend near Stirling, in 1804 to Stirling, and in 1810 to Edinburgh, in the society of which she was until her death a prominent figure, being much esteemed for her conversational powers, her tact and good sense, her cheerfulness of disposition, and her thorough kindness of heart. For the last twelve years of her life she received a pension from Government; and thus, along with her other sources of income, not only placed her in easy circumstances, but enabled her to gratify her generosity by giving to others. She died November 7, 1838.

See *Memoirs and Correspondence of Mrs Grant of Laggan*, edited by her son J. P. Grant, 3 vols., 1844.

GRANT, SIR FRANCIS (1803-1878), an English portrait painter, and president of the Royal Academy in London, was the fourth son of Francis Grant of Kilgraston, Perthshire, and was born at Edinburgh in 1803. He was educated for the bar, and, according to the testimony of Sir Walter Scott in his diary, it was originally his intention after spending his small patrimony in field sports to make his fortune by the law. By the time, however, that the first part of his purpose had been accomplished, he had resolved to adopt painting in preference to law as his profession, and at the age of twenty-four he began at Edinburgh systematically to study the practice of art. On completing a course of instruction he moved to London, and in early 1813 exhibited at the Royal Academy. At the beginning of his career he utilized his sporting experiences by painting groups of huntmen, horses, and hounds, such as the Meet of II M. Staghounds and the Melton Hunt, and doubtless if he had chosen to devote himself to the careful treatment of this class of subjects his success might have been more thorough and permanent, if less brilliant and lucrative, than it was. If, however, the reputation he acquired as a fashionable portrait painter was aided by his social position and gentlemanly manners, it rested also on certain special artistic qualifications. "The first and chief of these was his power of thoroughly reproducing the outward tone and manner of fashionable life, or, as Sir Walter Scott called it, his "sense of beauty derived from the best source, that is, the observation of really good society." If also his execution was superficial and thin, it was bright, clear, facile, and unostentatious. In display he had the taste of a connoisseur, and rendered the minutest details of costume with felicitous accuracy. In female portraiture he achieved considerable success, although rather in depicting the highborn graces and external characteristics than the true and individual personality. Among his portraits of this class may be mentioned Lady Glenlyon, the matchmaker of Waterford, Lady Rodney, and Miss Bouverie. In his portraits of generals and sportsmen he proved himself more equal to his subject than in those of statesmen and men of letters. He painted many of the principal celebrities of the time—especially those occupying high social position—including Scott, Macaulay, Lockhart, Disraeli, Haizinge, Gough, Deby, Palmerston, and Russell, his brother Sir J. Hope Grant, and his friend Sir Edwin Landseer. From the first his career was rapidly prosperous, and his recognition by the Academy fully kept pace with his reputation as an artist. In 1812 he was elected an associate, and in 1815 an Academician, and in 1866 he was chosen to succeed Sir C. Esdaile in the post of president, for which his chief recommendations were his social distinction, tact, urbanity, and friendly and liberal consideration of his brother artists, and his diffident and often invidious duties he performed so as both to increase the harmony and influence of the institution and to enhance its efficiency. Shortly after his election as president he received the honour of knighthood, and in 1870 the degree of D.C.L. was conferred upon him by the university of Oxford. He died October 5, 1878.

GRANT, SIR JAMES HOPKINS (1808-1875), an English general, brother of the preceding, and fifth and youngest son of Francis Grant of Kilgraston, Perthshire, was born July 22, 1803. He entered the army in 1826 as cornet in the 9th Lancers, and became lieutenant in 1828 and captain in 1835. In 1842 he acted as brigade-major to Lord Saltoun in the Chinese War, and specially distinguished himself at the capture of Oh-Kwang, after which he received the rank of major and was nominated companion of the bath. In the first Sikh War of 1845-46 he took part in the battle of Sobroon, and in the Punjab campaign of 1848-49 he held command of his old regiment the 9th

Lancers, and won high reputation in the battles of Chillianwalla and Gravel. In 1851 he became brevet-colonel, and in 1856 brigadier of cavalry. His first leading part in the suppression of the Indian mutiny of 1857, holding for some time the command of the cavalry division, and afterwards of a movable column of horse and foot. After rendering valuable service in the operations before Delhi and in the final assault on the city, he directed the victorious march of the cavalry and horse artillery despatched in the direction of Cawnpore to open up communication with the commander-in-chief Sir Colin Campbell, whom he met near the Alumbagh, and who raised him to the rank of brigadier-general, and placed the whole force under his command during what remained of the painful march to Lucknow for the relief of the residency. After the retirement towards Cawnpore he greatly aided in effecting the total rout of the rebel troops, by making a detour which threatened their rear, and following in pursuit with a flying column, he defeated them with the loss of nearly all their guns at Sassi Ghât. He also took part in the operations connected with the recapture of Lucknow, shortly after which he was promoted to the rank of major-general, and appointed to the command of the force employed for the final pacification of India, a position in which his untiring energy, and his vigilance and his devotion united to high personal daring, rendered very valuable service. Before the work of pacification was quite completed he was created K.C.B. In 1859 he was appointed to the command of the British land forces in the united French and British expedition against China, whose object was accomplished three months subsequent to the landing of the forces at Peh-tang, 1st August 1860, Peking having surrendered at discretion after the Chinese army had thrice suffered defeat in the open and the Taku forts had been carried by assault. For his conduct in this, which has been called "most successful and the best carried out of England's little wars," he received the thanks of parliament, and was gazetted G.C.B. In 1861 he was made lieutenant-general and appointed commander-in-chief of the army of Madras, on his return to England in 1865 he was made quartermaster-general at headquarters, and in 1872 he was transferred to the command of the camp at Aldershot. In the same year he was gazetted general. He died at London, March 7, 1875.

Insights into the Story of 1857-58, compiled from the Private Journal of General Sir James Grant, G.C.B., together with some extracts selected by David H. Stirling, Royal Artillery, was published in 1873, and Insights into the China War of 1860 appeared posthumously under the same editorship in 1876.

GRANTHAM, a municipal and parliamentary borough and market town of England, county of Lincoln, is situated on both sides of the Witham, at the junction of several railways with the Great Northern line, 105 miles N.N.E. of London and 22 miles S.W. of Lincoln. The parish church, a spacious Gothic edifice of the 13th century, has been restored by Sir G. G. Scott. It is surmounted by an elegant spire 274 feet high, and has an elaborately carved front, and some splendid monuments. At the free grammar school, founded by Bishop Fox in 1528, Sir Isaac Newton received part of his education. Among the other public buildings are the guild hall, with a spacious assembly-room, the two exchanges, the town-hall, the literary institution, the gaol, the dispensary, and the workhouse. A bronze statue of Sir Isaac Newton was erected in 1868. The principal trade is that of making, which is carried on to a considerable extent. There are also tanneries and coach factories, and a large agricultural implement factory and iron foundry. Grantham returns two members to parliament. The population of the municipal borough (area, 406 acres) in 1871 was 5028, and of the parliamentary borough (area, 5811 acres) 13,260.

GRANVELLA, ANTOINE PERRENET, CARDINAL, DE (1517-1588), one of the ablest and most influential of the princes of the church during the great political and ecclesiastical movements which immediately followed the appearance of Protestantism in Europe, was born 20th August, 1517, at Ornans, Burgundy, where his father, Nicolas Perrenet de Granvella, who afterwards became chancellor of the empire under Charles V., was at that time engaged in practice as a jurist at the provincial bar. On the completion of his studies in law at Padua and in divinity at Louvain, he for a short time held a canonry at Besançon, but his talents had already marked him for a higher sphere, and he was promoted the bishopric of Arras when barely twenty three (1540). In his episcopal capacity he attended several diets of the empire, as well as the opening meetings of the council of Trent, and the influence of his father, now become chancellor, led to his being entrusted with many difficult and delicate pieces of public business, in the execution of which he developed a rare native talent for diplomacy, and at the same time acquired an intimate acquaintance with most of the currents of European politics. One of his specially noteworthy performances was the settlement of the terms of peace after the defeat of the Smalkaldic league at Mühlberg in 1547, a settlement in which, to say the least, some particularly shap practice was exhibited. In 1550 he succeeded his father in the offices of secretary of state and chancellor of the empire, in this capacity he attended Charles in the war with Maurice, accompanied him in the fight from Innsbruck, and afterwards drew up the treaty of Passau (August 1562). In the following year he conducted the negotiations for the marriage of Mary of England and Philip of Spain, to whom in 1566, on the abdication of the emperor, he transferred his services. In April 1559 Granvella was one of the Spanish commissioners who arranged the peace of Cateau Cambrésis, and on Philip's withdrawal from the Netherlands in August of the same year he was appointed prime minister to the regent, Margaret of Parma. The policy of repression which in this capacity he pursued during the next five years secured for him many tangible rewards, in 1560 he was elevated to the archiepiscopal see of Malines, and in 1561 he received the cardinal's hat, but the growing hostility of a people whose moral and religious convictions he had studiously set himself to trample under foot, ultimately made it impossible for him to continue in the Low countries, and by the advice of his royal master he in 1564 retired to Franche Comté. Nominally this withdrawal was only a temporary character, but it proved to be final. The following six years were spent in comparative quiet, which was devoted chiefly to study and to the society of learned men, but in 1570 Granvella, at the call of Philip, resumed public life by accepting a mission to Rome as representative of the interests of Spain in framing the proposed treaty of alliance with Venice and the papal see against the Turks. In the same year he was advanced to the viceregency of Naples, a post of some difficulty and danger, which for five years he occupied with ability and success. Summoned to Madrid in 1575, to be president of the supreme council of Italy and afterwards that of Chastell, he still continued to find ample scope for his rare aptitudes. Among the more delicate negotiations of his later years were those of 1580, which had for their object the ultimate union of the crowns of Spain and Portugal, and those of 1584, which resulted in a check to France by the marriage of the Spanish infant to Duke Philip of Savoy. In the same year he was made archbishop of Besançon, but meanwhile a lingering disease had laid an unrelenting grasp upon his iron frame, he never was enthroned, but died at Madrid, 21st September 1588. His body was removed to Besançon, where his father had been buried before him.

Numerous letters and memoirs of Granvella are preserved in the archives of Levenson. These was to some extent made use of by Prosper Levesque in his *Mémoires pour servir* (1754), as well as by the Abbé Bonnet in the *Trésor de Granvella*. Commenson has published the whole of the letters and memoirs was appointed by Bonnet in 1834, and the result has been the issue of nine volumes of the *Papiers d'Etat du Cardinal de Granvella*, edited by Weiss (1841-1852). They form a part of the *Collection des mémoires relatifs sur l'histoire de France*. See also the many more *Histoire du Cardinal de Granvella*, attributed to Comte de Lamoignon (Paris, 1761), and Motley's *Rise of the Dutch Republic*.

GRANVILLE, a fortified seaport town of France, department of Manche, is situated at the mouth of the Dese, and at the foot of a steep rocky promontory projecting into the English Channel, 30 miles S W of St-Lô. It is surrounded by strong walls, and is built principally of granite, and its streets are mostly steep and narrow. The parish church dates from the 15th century. Among the other public buildings are the tribunal of commerce, the hospital, the public baths, and the naval school. Granville occupies the seventh place in point of importance among the seaports of France, and the harbour is accessible to vessels of the largest tonnage. There is regular steam communication with Jersey and Guernsey. The principal exports are fruits, vegetables, oysters, fish, corn, wool, and cattle. A large number of the inhabitants are engaged in the coal and oyster fisheries, and among the other industries is the manufacture of brandy, chemicals, cod-liver oil, and leather. Shipbuilding is also carried on. Granville was founded by the English in the beginning of the 15th century, taken by the French in 1480, bombarded and burned by the English in 1695, and partly destroyed by the Vendéens troops in 1793. The population in 1878 was 12,372.

GRANVILLE, JOHN CARTERET, EARL (1690-1763), English statesman, son of George, Lord Carteret, was born 23d April 1690, and in his fifth year succeeded to his father's title. He was educated at Westminster school, at Christ Church, Oxford, and even early in life had acquired a knowledge of the classics, of philosophy, of general literature, and of modern languages, which rendered him perhaps superior to all his contemporaries in the extent of his intellectual accomplishments. Soon after taking his seat in the House of Lords in 1711, he began to distinguish himself by his eloquent advocacy of the Protestant succession, and his zeal was rewarded when George I. came to the throne, by the appointment in 1715 of bailiff of the island of Jersey, and in 1716 of lord lieutenant of Devon, and his mother was also created countess of Granville. In 1719 he was sent on an embassy to Sweden, and in 1720 he was named ambassador-extraordinary to the congress of Cambrey. In May of the following year he was appointed secretary of state under Walpole's administration, but Walpole's jealousy of his influence with the king led to his resignation on the 3d April 1734, and on the same day he was appointed lord-lieutenant of Ireland, an office which he held till 1730, when differences with the ministry led to his resignation. After his return he became the leader of the opposition, the duties of which office he discharged with great versatility of resource and with frequent effectiveness, but with a neglectful rashness which rendered him almost as dangerous to his friends as to his opponents. In 1742 he was at last successful in overthrowing Sir Robert Walpole's Government, and was immediately thereafter appointed secretary of state. He now obtained a complete ascendancy over the mind of George II., whose German policy he carried out irrespective of the opinions of his colleagues, but his imperiousness soon gained him both their enmity and the hatred of the people, and enabled his opponents, for whom he cherished unmitigated contempt, to effect his political annihilation. Pitt, afterwards earl of Chatham, spoke of him as "an execrable, a sole monster, who had renounced the British nation, and seemed to have

drank of the potion described in poetic fiction, which made men forget their country." In 1744 he found it necessary, from the resignation of his colleagues and his inability to find proper successors, to tender his resignation, and, according to Horace Walpole, he "retired from St James's laughing." Shortly before this he had, by the death of his mother, become Earl Granville. His administration was popularly distinguished by the epithet "drunken"—a title which had reference to his character both as a politician and as a private individual. Notwithstanding his want of political success, contemporary opinion is unanimous in affirming that he was not only the most brilliant debater but the ablest statesman of his time. Chatham declared that he owed all that he was to his friendship and instruction, and Swift, Smollett, Chesterfield, and Horace Walpole have borne equally laudatory testimony to his abilities. He was besides regarded as an authority in questions of scholarship by the most eminent classicists of his time, and Bentley was greatly indebted to his assistance in preparing his edition of Homer. His fatal defects appear to have been his careless arrogance and his deficiency in definite political principle and purpose. After the resignation of the Pelham ministry he was again appointed secretary of state, but almost immediately resigned, holding office, according to a political squib, for only forty-eight hours, three quarters, seven minutes, and eleven seconds. In 1749 he was created knight of the garter and appointed president of the council, but, though he retained his influence with the king, the part he thereonforth played in English politics was indirect and subordinate. He died January 2, 1763.

Various information regarding Earl Granville will be found in Chesterfield's *Characters*, Lord Hovell's *Memoirs of the Reign of George II.*, Hon. W. Walpole's *Letters and Memoirs of George II.*, and the *Audubon History of Shalburne*. See also Locky's *History of England in the Eighteenth Century*.

GRAPE. See VINE.

GRAPHITE. See CARBON, vol v p 86, and FURNACE, vol ix p 843.

GRAPHOTYPE is a name which has been given to an ingenious process of autographic engraving, by which typographic printing blocks are produced. The general principles of the process are as follows. A block of chalk or some similar material is reduced to a level surface, and on this surface a design is drawn with a glutinous ink, this ink being sufficiently fluid to penetrate some little distance into the porous chalk. The ink having become dry, gentle friction is applied to the surface of the block, so as gradually to rub away those parts of the chalk which are not indurated by the glutinous ink. The lines of the drawing being thus left in relief, a perfect model of the required printing block is obtained, and this model is next hardened by immersion in a bath containing a solution of an alkaline silicate, after which it is dried and reproduced by the stereotype or the electrotype process. This method of typographic engraving was brought to a practical form, and patented in 1800 (No. 2309) by an American wood engraver, Mr de Witt Clinton Hitchcock. The first step in his process is to reduce French chalk or talc to an extremely fine state of division by repeated grindings, elutriations, and siftings, after which a layer of the material, rather over an eighth of an inch in thickness, is forced down upon, and made to adhere to, a thick zinc plate,—the necessary pressure being obtained by means of an hydraulic press, the plate of which is faced with a polished steel plate, so as to communicate a good surface to the layer of compressed French chalk. The device is now drawn (of course, reversed) on the prepared block with an ink consisting of a weak solution of glue coloured by lamp black or some other pigment. In drawing on the prepared block care must be taken not to damage the somewhat tender surface of the compressed chalk, and the safest instrument with which to apply the

glutinous ink is a fine sable brush, but an ordinary pen may be employed if the operation of drawing is performed with caution. A pad of silk velvet or a fish brush may be used for rubbing the block so as to leave the lines in relief, and it is quite sufficient to continue the friction until a depth equal to the thickness of an ordinary playing card is produced,—the spaces corresponding to any extended whites of the engraving being then cut out by means of a tool. A 10 per cent solution of silicate of sodium may be used for hardening the block, and when dry nothing remains but to take a mould from it and to reproduce it in metal.

GRASLITZ, or GRASLITZ (Bohemian *Graslitz*), a town in the north-west of Bohemia, near the Saxon frontier, in the circle of Elbogen, 88 miles N W of Prague, 50° 21' N lat., 12° 27' E long., is advantageously situated in a valley between high hills, at the confluence of the Silberbach and Zwoda. It is the headquarters of a military district, the seat of a court of justice, and has a custom house, a handsome church built in 1618 and dedicated to Corpus Christi, and several manufactures of cotton and woollen stuffs, and of musical and mathematical instruments, looking-glasses, brass, copper, and wire goods, and paper. Graslitz is one of the most important industrial towns in Bohemia, and the centre of the lace weaving districts of the Kingdom. In 1869 the population, inclusive of the small suburb of Glasberg, amounted to 6549.

GRASSE, a town of France, capital of an arrondissement in the department of Alpes Maritimes, 20 miles W of Nice. It occupies a picturesque situation on the southern declivity of a hill facing the Mediterranean, from which it is about 7 miles distant, and it possesses a climate remarkably mild and salubrious. It is well supplied with water from a rivulet which rises above it. The streets are narrow, steep, and winding, but the houses are generally well built. The town was formerly the seat of a bishop, and possesses a Gothic cathedral with a beautiful tower, an old chapel dating from the 11th century, now used as a powder magazine, a hospital, a town-hall, an exchange, a theatre, a communal college, and a public library. The chapel of the hospital contains three pictures by Rubens. Next to Paris, Grasse contains the largest manufacture of perfumery in France. Citrons, oranges, lemons, figs, pomegranates, and the flowers used by the perfumers, are grown in the gardens of the town and neighbourhood, and fine marble, alabaster, and jasper are found in the vicinity. Grasse was founded in the 6th century by Jews from Sardinia. The population in 1876 was 9673.

GRASSES (*Gramineæ*—*Gramina*) are monocotyledonous flowering plants, possessing certain characters in common, and constituting the order *Gramineæ*. No plant is correctly termed a grass which is not a member of this family, but the word is in common language also used, generally in combination, for many plants of widely different affinities which possess some resemblance (often slight) in foliage to truly grassaceous species, e.g., knot-grass (*Polygonum aviculare*), cotton grass (*Lythrum*), rib-grass (*Plantago*), scorpion-grass (*Myosotis*), sea grass (*Zostera*). In agriculture the word has an extended significance to include the various fodder plants, chiefly leguminous, often called "artificial grasses" (see *ACACIACEÆ*). Indeed, formerly grass (also spelt *gare*, *giet*, *gyre*, in the old herbals) meant any green herbaceous plant of small size.

Yet the first attempts at a classification of plants recognized and separated a group—considered even of primary value—of *Gramina*, and thus, though bounded by nothing more definite than habit and general appearance, contained the *Gramineæ* of modern botanists. The older group, however, even with such systematists as Ray (1703), Schenckler (1719), and Michx. (1729), embraced in addition the *Cyperaceæ*, *Juncaceæ*, and some other mono-

cotyledons with inconspicuous flowers. Singularly enough, the sexual system of Linnaeus (1735) served to mark off more distinctly the true grasses from these allies, since very nearly all of the former then known fall under his Triandria Digynia, whilst the latter found themselves under other of his artificial classes and orders.

I. STRUCTURE.—The general type of true grasses is familiar in the cultivated cereals of temperate climates—wheat, barley, rye, oats, and in the smaller plants which make up our pastures and meadows and form a principal factor of the turf of natural downs. Less familiar are the grains of warmer climes—rice, maize, millet, and sorgho, or the sugar cane. Still further removed are the bamboos of India and America, the columnar stems of which reach to the heights of forest trees. All are, however, formed on a common type, which we proceed to examine.

Root.—Most cereals and many other grasses are annual, and possess a tuft of very numerous slender root-fibres, much branched, and of great length. The greater part of the order are of longer duration, and have the roots also fibrous, but fewer, thicker, and less branched. In such cases they are very generally given off from just above each node (often in a circle) of the lower part of the stem or rhizome, performing the leaf-sheath. In some bamboos they are very numerous from the lower nodes of the erect culms, and pass downwards to the soil around them, whilst those from the upper nodes shrivel up and form circles of spiny fibres.

Stem.—The root-stock of perennial grasses is usually well developed, and often forms very long creeping or subterranean rhizomes, with elongated internodes and sheathing scales; it is also frequently short, with the nodes crowded. The very large root-stock of the bamboos (fig. 1) is a striking

FIG. 1.—Rhizome of Bamboo. A, B, C, D, successive series of axes, the last bearing aerial culms.

ing example of "definite" growth; it is much branched, the short thick curved branches being given off below the apex of the older ones and at right angles to them, the whole forming a series of connected arched axes, truncate at their ends which were formerly continued into leafy culms. The root-stock is always solid, and has the usual internal structure of the monocotyledonous stem.

The aerial leaf-bearing branches (culms) are a characteristic feature of grasses. They are generally numerous, erect, cylindrical (rarely flattened), and conspicuously jointed with evident nodes. The nodes are solid, a strong plate of tissue passing across the stem, but the internodes are commonly hollow, although examples of completely solid stems are not uncommon (many *Andropogon*, *Imperata*, &c.). The general character is thus not unlike that of *Umbelliferae*. The exterior of the culms is more or less concealed by the leaf-sheaths; it is usually smooth and often highly polished, the epidermal cells containing an amount of silica sufficient to leave after burning a distinct skeleton of their structure. Tabasheer is a white substance mainly composed of silica, found in the joints of several bamboos. A few of the lower internodes may become eu-

larged and sub-globular, forming nutrient-stores, and grasses so changed are termed "bulbous" (*Arrhenatherum*, *Poa bulbosa*, &c.). In internal structure grass-culms, save in being hollow, conform to that usual in monocotyledons; the vascular bundles run parallel in the internodes, but a horizontal interlacement occurs at the partitions. Nearly all grasses branch to some extent, and many extensively; the branches are strictly distichous, and many buds are abortive, or the resulting branches short and stunted. In many bamboos they are long and spreading or drooping and copiously ramified, in others reduced to hooked spines. *Dincolles* is truly scandent, and climbs over trees 100 feet or more in height. *Olyra latifolia* is also a climber on a humbler scale.

Grass-culms grow with great rapidity, as is most strikingly seen in bamboos, where a height of over 100 feet is attained in from two to three months, and many species grow two, three, or even more feet in twenty-four hours. Silicle hardening does not commence till the full height is nearly attained. The largest bamboo recorded is 170 feet, and the diameter is usually reckoned at about 4 inches to each 60 feet. A specimen in the British Museum is over 8 inches in diameter. In the same collection are some remarkable monostichosis, in which the edges are oblique and the internodes triangular or rhomboidal; Kurz has also figured one in the Calcutta Museum in which the cavities are confluent into a continuous spiral.

Leaves.—These present special characters usually sufficient for ordinal determination. They are always solitary at each node and strictly distichous, and consist of two distinct portions, the sheath and the blade. The sheath is often of great length, and generally completely surrounds the culm; as a rule it is split down its whole length, thus differing from that of *Cyperaceae*, which is almost invariably (*Eriopora* is an exception) a complete tube. In a few grasses (*Meica*, *Bromus*) the edges are soldered together as in the latter order. The sheaths are much dilated in *Alopecurus vaginatus* and in a species of *Panicum*, in the latter serving as flants. At the summit of the sheath, above the origin of the blade, is the *ligule*, a usually membranous process of small size (occasionally reaching an inch in length) erect and pressed around the culm. It is rarely quite absent, but may be represented by a tuft of hairs (very conspicuous in *Panicum*). *Meica unyiflora* possesses, in addition to the ligule, a green erect tongue-like process, from the line of junction of the edges of the sheath.

The blade is frequently wanting or small and imperfect in the basal leaves, but in the rest is long and set on to the sheath at an angle. The usual form is laminae, sessile, more or less ribbon-shaped, tapering to a point, and entire at the edge. The chief modifications are the articulation of the (deciduous) blade on to the sheath, which occurs in all the *Bambuseae* (except *Planotia*) and in *Spartina stricta*, and the interposition of a petiole between the sheath and the blade, as in *Leptagis*, *Pharus*, *Panicum*, *Lophatherum*, &c. In the latter case the form of the leaf usually becomes oval, ovate, or even cordate or sagittate, but these forms are found in sessile leaves also (*Olyra*, *Panicum*). The venation is strictly parallel, the midrib usually strong, and the other ribs more slender. In *Anomoechloa* there are several nearly equal ribs, and in some broad-leaved grasses (*Bambusa*, *Pharus*, *Leptagis*) the venation becomes tessellate by transverse connecting veins. The thick prominent veins in *Agropyrum* occupy the whole upper surface of the leaf. Epidermal appendages are rare, the most frequent being marginal, saw-like, cartilaginous teeth, usually minute, but occasionally (*Danthonia scabra*, *Panicum verrucosum*) so large as to give the margin a serrate appearance. *Alopecurus lanatus* and one or two *Panicums* have woolly leaves.

Inflorescence.—This possesses an exceptional importance in grasses, since, their floral envelopes being much reduced and the sexual organs of very great uniformity, the characters employed for classification are mainly derived from the arrangement of the flowers and their investing bracts. The subject also presents unusual difficulties from the various interpretations which have been given to these glutumaceous organs and the different terms employed for them by various writers. It may, however, be now considered as settled that the whole of the bodies known as glumes and palea, and distichously arranged externally to the flower, form no part of the floral envelope, but are of the nature of bracts. These are so arranged that the small flowers as to form *spikelets* (locusses), and each spikelet may contain one, two, three, or a greater number of flowers (in some species of *Brizopsis* nearly 60). The flowers are, as a rule, placed laterally on the axis (rachis) of the spikelet, but in uniflorous spikelets they appear to be terminal, and are probably really so in *Anthoxanthum* (fig. 9, 2) and in two anomalous genera, *Anomochloa* and *Sis epochete*.

In immediate relation with the flower itself, and often entirely concealing it, is the *palea* or *pale* ("upper pale" of most systematic agrostologists, "paleola interior," Dumortier, "epigynum," Doll). The organ (fig. 3, 1) is peculiar to grasses among *Gymnosperms*, and is almost always present, certain *Oryxæ* and *Phalarides* being the only exceptions. It is of thin membranous consistence, usually obtuse, often bilobed, and possesses no central rib or nerve, but is furnished with two lateral ones, one on either side, the margins are frequently folded in at the ribs, which thus become placed at the sharp angles. This structure points to the fusion of two organs, and the pale was by R. Brown considered to represent two portions soldered together of a tumorous perianth-whorl, the third portion being the "lower pale," to be immediately mentioned. By Bentham the homology of the organ is suggested to be with the two bracteoles found in *Lythrum purpureum* and *Platylis*, and with the perygium of the female flower of *Cissæ* in *Oxytropis*. It is rarely (*Trachypogon*, *Drachypogon*) found split into two separate organs.

The flower with its pile is sessile, and is placed in the axil of another bract in such a way that the pale is exactly opposed to it, though at a slightly higher level. It is this second bract which has been generally called by systematists the "lower pale," and with the "upper pale" considered to form an outer floral envelope ("calyx," Jussieu, "perianthium," Brown, "stigmulum," Palisot de Beauvois, "glumella," Dumortier). In the writings of most botanists even though this view is not held, yet, where the term "flower" is employed, it includes these organs. It is, however, certain that the two bracts are on different axes, one secondary to the other, and cannot therefore be parts of one whorl of organs. This was made out from the study of so-called "viviparous" grasses, in which the lower pale becomes transformed into ordinary foliaceous leaves, first by Von Mohl in 1846, and more clearly by Germain de St. Pierre in 1852, who terms the lower pale the "glume fertile." Doll and Bentham have also independently arrived at the same result, and the latter in 1858 first published the terminology here adopted, and used for the same organ the name *flowering glume*. The two bracts are usually quite unlike one another, but in some genera (e.g., most *Festucaceæ*) they are considerably similar in shape and appearance.

The flowering glume has generally a more or less boat-shaped form, is of firm consistence, and possesses a well-marked central midrib and frequently several lateral ones. The midrib in a large proportion of genera extends into an appendage termed the *awn* (fig. 10, 2), and the lateral veins

more rarely extend beyond the glume as sharp points (e.g., *Pappophyrum*). The form of the flowering-glume is very various, this organ being plastic and extremely modified in different genera. In *Lopholophium* it is formed into a closed cavity by the union of its edges, and encloses the flower, the styles projecting through the perversus summit. Valuable characters are obtained from the awn. This presents itself variously developed from a mere subulate point to an organ several inches in length, and when complete (as in *Aristopogon*, *Arnece*, and *Silene*) consists of two well marked portions, a lower twisted part and a terminal straight portion, usually set in at an angle with the former sometimes bifid and occasionally beautifully feathery. The lower part is most often suppressed, and in the large group of the *Panicæ* awns of any sort are very rarely seen. The awn may be either terminal or may come off from the back of the flowering-glume, and Duval Jouve's observations have shown that it represents the blade of the leaf of which the portion of the flowering-glume below its origin is the sheath, the twisted part (so often suppressed) corresponds with the petiole, and the portion of the glume extending beyond the origin of the awn (very long in some species, e.g., of *Danthonia*) with the ligule of the developed foliaceous leaf. When terminal the awn has three fibro-vascular bundles, when dorsal only one, it is covered with stomate-bearing epidermis.

The flower with its palea is thus sessile in the axil of a floriferous glume, and in a few grasses (*Leuca* (fig. 2), *Coleanthus*, *Nardus*) the spikelet consists of nothing more, but usually (even in uniflorous spikelets) other glumes are present. Of these the two placed distichously opposite each other at the base of the spikelet never bear any flower in their axils, and are called the *basal* or *empty glumes* (fig. 10, 1). They are the "glumes" of most writers ("paleæ" of Dumortier, and together form what was called the "glume" by R. Brown ("segment," Palisot de Beauvois). They rarely differ much from one another, but one may be smaller or quite absent (*Panicum* (fig. 8, 2), *Ptilopus*, fig. 2—*spikelet of Lieria*), *Paspalum*, *Lolium*), or both be altogether suppressed, as above noticed. They are commonly firm and strong, often enclose the spikelet, and are rarely provided with long points or imperfect awns. Generally speaking they do not share in the special modifications of the flowering glumes, and but rarely themselves undergo modification, chiefly in the hardening of portions (*Silene*, *Alnus*, *Marrubium*, *Antephora*, *Peltopogon*), so as to afford greater protection to the flowers or fruit. But it is usual to find, besides the basal glumes, a few other empty ones, and these are in two or more-flowered spikelets (fig. 11, 2) at the extremity (numerous in *Lophanthurum*), or in uniflorous ones (fig. 8, 2) below, interspersed between the floral glume and the basal pair. Descriptive writers have been accustomed to call these empty glumes "barren" or "neutral flowers," a misleading use of terms.

The axis of the spikelet, when short and rounded, has been termed the *callosus*, when long the *rachis*. It is frequently jointed and breaks up into articulations above each flower. Trifts or borders of hairs are frequently present as to surround and conceal the flowers. The axis is often continued beyond the last flower or glume as a bristle or stalk.

Involution is or organs outside the spikelets are not infrequent, the morphology of which is various. Thus in *Setaria*, *Pennisetum*, &c., the one or more circles of simple or feathery hairs represent abortive branches of the inflorescence, in *Cenchrus* these become consolidated, and the

inner ones flattened out so as to form a very hard globular spiny case to the spikelets. The cup-shaped involucre of *Cornucopia* is a dilatation of the axis into a hollow receptacle with a raised border. In *Cynurus* the pectinate involucre which conceals the spikelet is a barren or abortive spikelet. True bracts of a more general character subtending branches of the inflorescence are singularly rare in *Gramineae*, in marked contrast with *Cyperaceae*, where they are so conspicuous. They however occur in a whole section of *Andropogon*, in *Anomochloa*, and at the base of the spike in *Sclerium*. The remarkable ovoid involucre of *Coix*, which becomes of stony hardness, white, and polished (then known as "Job's tears"), is also a modified bract or leaf-sheath. It is entirely closed except at the apex, and contains the female spikelet, the stalks of the male inflorescence and the long styles emerging through the small apical orifice.

Any number of spikelets may compose the inflorescence, and their arrangement is very various. In the spicate forms, with sessile spikelets on the main axis, the latter is often tilted and flattened (*Paspalum*), or is more or less thickened and hollowed out (*Stenotaphrum*, *Rottboellia*, *Tripsacum*), when the spikelets are sunk and buried within the cavities. Every variety of racemose and panicle-like inflorescence obtains, and the number of spikelets composing those of the large kinds is often immense. Rarely the inflorescence consists of very few flowers; thus *Lygnum Spartum*, the most anomalous of European grasses, has but two or three large uniflorous spikelets, which are fused together at the base, and have no basal glumes, but are enveloped in a large hooded spathe-like bract.

Flower.—This is characterized by remarkable uniformity. The perianth is represented by very rudimentary, small, fleshy, hypogynous scales called lodicules ("squamule,"

Fig. 6.—Flowers of Grasses. 1, *Piptatherum*, with the palea; 2, *Poa*; 3, *Oryza*. Kunth; "nectarium," Schreber; they are elongated or truncate, sometimes fringed with hairs, and are in contact with the ovary. Their usual number is two, and they are placed collaterally at the anterior side of the flower, that is, within the flowering glume. They are generally considered to represent the inner whorl of the ordinary monocotyledonous (Ullaceous) perianth, the outer whorl of these being suppressed as well as the posterior member of the inner whorl. This latter is present almost constantly in *Stipeae* and *Bambuseae*, which have three lodicules, and in the latter group they are occasionally more numerous (five, spreading and persistent in *Pseudostachyum*; six to eight in *Bealia*). In *Anomochloa* they are represented by hairs. In *Streptochaeta*, according to Deill, there are six lodicules, alternately arranged in two whorls. They are often quite absent. In some cases lodicules are of the nature of stipules to the palea, and appear as though split off from its sides at the base. Such stipular lodicules often co-exist along

with the perianthial ones, and are then either free from or combined with the two anterior ones.

Sexual Organs.—Grass-flowers are usually hermaphrodite, but there are very many exceptions. Thus it is very common to find one or more imperfect (usually male) flowers in the same spikelet with bisexual ones, and their relative position is important in classification. *Holcus* and *Arrhenatherum* are examples in English grasses; and as a rule in species of temperate regions separation of the sexes is not carried further. In warmer countries monocious and dioecious grasses are more frequent. In such cases the male and female spikelets and inflorescences may be very dissimilar, as in the maize, Job's tears, *Euchlana*, *Spinifex*, &c.; and in some dioecious species this dissimilarity has led to the two sexes being referred to different genera (e.g., *Antephora axilliflora*, Steud., is the female of *Buchloe dactyloides*, Engelm., and *Neurachne paradoxa*, Br., of a species of *Spinifex*). In other grasses, however, with the sexes in different plants (e.g., *Brisopyrum*, *Distichlis*, *Eragrostis capillata*, *Gynerium*), no such dimorphism obtains. *Amphicarpum* is remarkable in having cleistogamic flowers borne on long radical subterranean peduncles which are fertile, whilst the conspicuous upper paniculate ones, though apparently perfect, never produce fruit. Something similar occurs in *Leersia oryzoides*, where the fertile spikelets are concealed within the leaf-sheath.

Androecium.—In the vast majority there are three stamens alternating with the lodicules, and therefore one anterior, i.e., opposite the flowering glume, the other two being posterior and in contact with the palea. They are hypogynous, and have long and very delicate filaments, and large, linear or oblong two-celled anthers, dorsifixed and ultimately very versatile, deeply indented at each end, and commonly exerted and pendulous. Suppression of the anterior stamen sometimes occurs (e.g., *Anthoxanthum*), or the two posterior ones may be absent (*Uniola*, *Cinna*, *Phizopoda*, *Festuca bromoides*). On the other hand there is in some genera (*Oryza*, most *Bambuseae*) another row of three stamens, making six in all (fig. 3, 3); and *Anomochloa* and *Tetrarrhena* possess four. The stamens become numerous (ten to forty) in the male flowers of a few monocious genera (*Pariana*, *Luxiola*). In *Besha* they vary from seven to thirty, and in *Gigantochloa* they are monadelphous.

Gynaeceum.—There is but little variation here from a bicarpellary pistil, with a small rounded one-celled ovary containing a single laterally attached or ascending ovule, capped by two styles quite distinct or connate at the base,

Fig. 4.—Pistils of Grasses. 1, *Alopecurus*; 2, *Bromus*; 3, *Arrhenatherum*; 4, *Oryza*; 5, *Setaria*; 6, *Milium*; 7, *Panicum*.

and with densely silky or feathery stigmas (fig. 4). Occasionally there is but a single style (*Nardus*, *Lygnum*), and they may attain to a great length (6 inches in the maize); or three styles may be present (some *Bambusae*, *Leptaspis*, *Streptochaeta*). Nees has described a case in which three complete carpels were found in *Schedonorus elatior*.

We thus see that, comparing the flower of *Gramineæ* with the normal thiosperm plan (fig 5), it differs in the complete suppression of the outer row and the posterior member of the inner row of the perianth-leaves, of the whole inner row of stamens, and of the anterior carpel, whilst the remain-

FIG 5.—Diagrams of the ordinary grass flower. 1, actual condition. 2, theobed, with the suppressed organs supplied. a, anther; b, staminal tube; c, palea; d, outer row of perianth leaves; e, inner row; f, outer row of stamens; g, inner row; h, pistil.

ing members of the perianth are in a rudimentary condition. But each or any of the usually missing organs are to be found normally in different genera, or as occasional developments.

Fruit—The ovary ripens into a usually small ovoid or rounded fruit, which is entirely occupied by the single large seed, from which it is not to be distinguished, the thin pericarp being completely united to its surface. To this peculiar fruit the term *caryopsis* has been applied (more familiarly "grain"), it is commonly furrowed longitudinally down one side (usually the inner, but in *Cow* and its allies, the outer), and an additional covering is not unfrequently provided by the adherence of the persistent palea, or even also of the flowering glume ("chaff" of cereals). From this type are a few deviations, thus in *Sporobolus*, &c. (fig 6), the pericarp is not united with the seed but is quite distinct, dehiscens, and allows the loose seed to escape. Sometimes the pericarp is more branched, sometimes hard and brittle, whilst, on the other hand, in some genera of *Bambuseæ*, it becomes thick and fleshy, forming a "berry," the fruit or rather a drupe. In *Melovanica bicusper* a tuft of *Sporobolus* forms a fruit 3 or 4 inches long, with a pointed apex, and a beak of 2 inches more, it is indehiscent, and the small seed germinates whilst the fruit is still attached to the tree, putting out a tuft of roots and a shoot, and not falling till the latter is 6 inches long. A similar germination also occurs in *Pseudotschuyum compactum*, which has the largest fruit of the order.

Seed—The testa is thin and membranous but occasionally coloured, and the embryo small, the great bulk of the seed being occupied by the hard farinaceous endosperm (albumen) on which the nutritive value of the grain depends.

FIG 7.—A grain of wheat. 1, back; and 2, front view. 3, vertical section, showing (a) the endosperm, and (b) the embryo; 4, commencement of germination, showing (a) the plumula, and (b) the secondary rootlets surrounded by their coleorhiza.

The embryo presents many points of interest. Its position is remarkable, closely applied to the surface of the endosperm at the base of its outer side. This character is absolute for the whole order, and effectually separates *Gramineæ* from *Cyperaceæ*. The part in contact with the endosperm

is flat and plate-like, and is known as the *ventrum*. Some difference of opinion is held as to the nature of this, but it is probably correctly regarded (as by Van Rueden) as the main portion of the cotyledon, the white edge of which (*epicotyle*) protecting the plumule—which is often described as the cotyledon—being the ligule only of that organ greatly developed. The radicle is inferior, broad, and blunt, the primary root is very slightly developed in germination, but several secondary lateral ones burst through above its point, and thus become surrounded at their base with little silicles (coleorrhizæ).

CLASSIFICATION—*Gramineæ* are thus sharply defined from all other plants, and there are no characters to which it is possible to feel a doubt whether they should be referred to it or not. The only order closely allied is *Cyperaceæ*, and the points of difference between the two have been alluded to above, but may be here brought together. The best distinctions are found in the position of the embryo in relation to the endosperm—lateral in grasses, basal in *Cyperaceæ*—and in the possession by *Gramineæ* of the 2-nerved palea below each flower. Less absolute characters, but generally trustworthy and more easily observed, are the feathery stigmas, the always distinct anthers of the glumes, the usual absence of more general bracts in the inflorescence, the split leaf sheaths, and the hollow, cylindrical, jointed culms,—some or all of which are wanting in all *Cyperaceæ*. The same characters will distinguish grasses from the other glumiflorous orders, *Restiacæ*, *Eriacaceæ*, and *Desfontainiaceæ*, which are besides further removed by their caperful fruit and pendulous ovules. To other monocotyledonous families the resemblances are merely of adaptive or vegetative characters. Some *Commelinaceæ* and *Muscaceæ* approach grasses in foliage, the leaves of *Ailanthus*, &c., possess a ligule, the habit of some palms reminds one of the bamboos, and *Juncaceæ* and a few *Liliaceæ* possess an inconspicuous scarious perianth.

The great uniformity among the very numerous species of this vast family renders its classification very difficult. The difficulty has been increased by the confusion resulting from the multiplication of genera founded on slight characters, and from the description of identical plants under several different genera in consequence of their wide distribution.

No characters for main divisions can be obtained from the flower proper or fruit, though both Kunth and Reichenbach have used them—especially the form of the styles and stigmas, the lodicules and the canes—they have not been generally employed by botanists, who have found it necessary to trust to characters derived from the usually less important inflorescence and bracts.

The earlier authors made the general arrangement of the spikelets (spicula, panicula, &c.) the basis of their classifications. Paillet de Beauvois's main divisions are founded on the existence in the same inflorescence of similar or diverse spikelets. Fries has proposed a division into *Euryanthæa* and *Oliganthæa*, according to the condition of the flowering glume and palea, sepalated or close during inflorescence. Dumortier gives a classification into *Reichardia*, *Rachidiflora*, and *Calyptrocha*, the first with the spikelets inserted into excavations of the rachis, the second with the flowers of the free spikelet inserted on its axis (rachilla), and the last with the flower or flowers borne on the short callus of the glumes. Both these systems, and others which have been suggested, possess merits of their own, but they have not as yet been found capable of application to the order as a whole, having been framed for the accommodation mainly of European genera.

For such general treatment no better primary divisions have been found than those proposed by Robert Brown in 1810 and further elaborated in 1814, which have

been accepted by Munro (1868) and Bentham (1878) in their most recent revisions of the Cape and Australian genera. The basis of Brown's division of the whole order into *Panicæ* and *Poaceæ* is the position of the most perfect flower in the spikelet; this is the upper (apparently) terminal one in the first, whilst in the second it occupies the lower position, the more imperfect ones (if any) being above it. Munro has supplemented this by another character easier of verification, and of even greater constancy, in the articulation of the pedicel in the *Panicæ* immediately below the glumes; whilst in *Poaceæ* this does not occur, but the axis of the spikelet frequently articulates above the pair of empty basal glumes. Neither of these two great divisions will well accommodate certain genera allied to *Phalaris*, for which Brown proposed tentatively a third group (since named *Phalarideæ*); this, or at least the greater part of it, is placed by Bentham under the *Poaceæ*.

The following arrangement is based on the writings of these authors, but it cannot be considered very satisfactory. Probably no serial disposition can represent the tangled network of genera related in different ways and various degrees which make up this very natural but complicated family, and though some of the following tribes are fairly natural, the limits of others are but ill-defined, and the position of many genera uncertain.

I. **PANTOCEÆ**.—Pedicel articulated below the glumes. Spikelet with one or two flowers, the more perfect fertile one above, the male or barren one, if present, below it.

FIG. 8.—*PANTOCEÆ*. 1, a pair of spikelets of *Andropogon*; 2, spikelet of *Setaria*, with an abortive branch beneath it.

1. *Pantoceæ*.—Spikelets with an apparently terminal hermaphrodite or female flower with or without a male one beneath it. Glumes three or four, the upper flowering one of a firm texture, the lowest usually small, sometimes absent. Awns rarely found; if present, neither twisted nor knused. Fruit enclosed in the hardened flowering glume and palea.

EXAMPLES.—*Tragus*, *Panicum*, *Pennisetum*, *Setaria*, *Pennisetum*, *Anthephora*, *Thouarea*, *Syntherisma*.

2. *Tristylidææ*.—Spikelets as in *Pantoceæ*, but flowering-glume with a twisted and bent awn.

EXAMPLES.—*Arundinella*, *Tristachya*, *Polypogon*(?).

3. *Andropogonææ*.—Spikelets as in the last, but usually in pairs (rarely three or solitary), one being sessile and fertile, the other stalked and usually monospermous. Glumes four (rarely fewer), one of the outer ones the largest and enclosing the fruit, the upper flowering one very thin and transparent, usually bearing a twisted and bent awn or reduced to the awn.

EXAMPLES.—*Echinochloa*, *Pennisetum*, *Andropogon*, *Imperata*, *Sorghum*, *Ambrosia*, *Brizantha*, *Echinochloa*, *Andropogon*.

4. *Rottboellidææ*.—Spikelets as in the last; one of each pair fertile, sessile, and sunk in alternate notches or cavities of the jointed simple rachis, the other staminal or absent; no awns.

EXAMPLES.—*Hemerodictyon*, *Misomeris*, *Rottboellia*, *Oxyrius*, *Polypogon*, *Lycopodium*.

5. *Mayadææ*.—Spikelets monospermous, very unlike, the male numerous in a terminal panicle, the female few at the base of the male inflorescence or more numerous in a separate one.

EXAMPLES.—*Citrus*, *Zea*, *Oryza*, *Tripsacum*, *Sclerocarpus*.

6. *Olyceæ*.—Spikelets monospermous, or some hermaphrodite and some male in the same panicle; the flowering glume large, sometimes utricular. Stamens three, six, or more. Leaves often broad and petioled.

EXAMPLES.—*Lycopodium*, *Pharus*, *Olyra*, *Pariana*.

- II. **PHALARIDÆÆ**.—Pedicel either articulated below the glumes or not, but the rachis of the spikelet articulated above the two lowest ones. Spikelets with one or three flowers, the perfect fertile one above, the two male, if present, below it. Two-nerved palea usually absent.

EXAMPLES.—*Phalaris*, *Anthoxanthum*, *Eriochloa*, *Hierochloa*, *Alopecurus*, *Phleum*, *Oxyria*, *Lycopodium*(?).

FIG. 9.—*PHALARIDÆÆ*. 1, spikelet of *Hierochloa*; 2, spikelet of *Anthoxanthum*.

- III. **POACEÆ**.—Pedicel not articulated below the glumes. Rachis of spikelet often articulated above the two lowest glumes. Spikelets with one, two, or more fertile flowers, the male or imperfect ones (if any) above them. Rachis of spikelet often continued as a point or bristle beyond the flowers.

1. *Oryzææ*.—Spikelets one-flowered. Empty basal glumes very small or wanting. Two-nerved palea usually absent. Stamens usually six.

EXAMPLES.—*Oryza*, *Leceria*, *Potamogeton*, *Eizania*, *Anomochloa*(?).

2. *Sitææ*.—Spikelets one-flowered. Flowering glume with a terminal twisted and bent awn. Palea small and thin. Lodicules three.

EXAMPLES.—*Sitona*, *Arundinella*, *Pyrotherium*.

3. *Agrostidææ*.—Spikelets one-flowered. Flowering glume usually with a terminal or dorsal bent awn. Palea small and thin. Lodicules two.

EXAMPLES.—*Agrostis*, *Dejageria*, *Calamagrostis*, *Calamagrostis*(?).

FIG. 10.—*POACEÆ*. 1, spikelet of *Agrostis*; 2, spikelet of *Alopecurus*.

4. *Alopecurææ*.—Spikelets generally two, rarely three or more-flowered. Flowering glumes with a terminal or dorsal bent and twisted awn. Palea large, enclosing with the flowering glume the fruit.

EXAMPLES.—*Alopecurus*, *Halimololium*, *Arthraxon*, *Alopecurus*, *Trisetum*, *Dactyloctenium*, *Lagurus*.

- [3, 4, and 4 together form Bentham's tribe *Stegothalææ*.]

5. *Pappophorææ*.—Spikelets one- or several-flowered. Flowering glumes rounded on the back, terminating in three or more teeth often carried out into straight awns.

EXAMPLES.—*Pappophorum*, *Trisetum*, *Catena*, *Trisetum*.

6. *Chloridææ*.—Spikelets one- or several-flowered, sessile on condensed spikes. Flowering glumes rarely awned.

Africae Planta*, ed. 2 (1882), 1d, *Bombay*, in *Trans. Linn. Soc. Lond.*, xvi, p. 1 (1883), David Joule, in *Mém. de l'Acad. des Sciences de Montpellier* (1871), Van Tieghem, in *Ann. des Sc. Nat.*, 5, xv, p. 246 (1875), *Berlin*, *Wiedersheim*, 1 (1876), *Strasbourg*, in *Bull. Soc. Ent. Belg.*, vi, p. 469 (1876) (11 T).

GRASSHOPPER (French *Sauterelle*, Italian *Grillo*, German *Grashopper*, *Heuschrecke*, Swedish *Grashoppa*), a collective term applied to certain orthopteran insects belonging to the families *Locustidae* and *Acyrididae*, according to the now generally received classificatory views. They are especially remarkable for their saltatory powers, due to the great development of the hind legs, which are much longer than the others and have stout and powerful thighs, and also for their stridulation, which is not always an attribute with them of this order only. The distinctions between the two families may be briefly stated as follows. — The *Locustidae* have very long thread-like antennae, and four-jointed tarsi, the *Acyrididae* have short stout antennae, and three-jointed tarsi. As the term "grasshopper" is almost synonymous with Locust, the subject will be more extensively treated under the latter heading (q. v.). Under both "grasshoppers" and "loenst" are included members of both families above-noticed, but the group belonging to the *Acyrididae* as such are in Britain the term is chiefly applicable to the large green grasshopper (*Locusta viridissima*) common in most parts of the south of England, and to smaller and more obscure species of the genera *Stenobothrus*, *Gomphocerus*, and *Tettix*, the latter remarkable for the great extension of the pronotum, which often reaches beyond the extremity of the body. All are vegetable feeders, and is in all orthopteran insects, have an incomplete metamorphosis, so that their destructive powers are continuous from the moment of emergence from the egg till death. The notorious migratory locust (*Pachytatus migratorius*) may be considered only an exaggerated grasshopper, and the more famous Rocky Mountain locust (*Calopterus apterus*) is still more entitled to the name. In Britain the species are not of sufficient size, nor of sufficient numerical importance, to do any great damage, and their cheerful "song" more than counteracts the slight mischief they may cause in devouring grasses and other plants. The columns of many of them accumulated greatly to those of their habitats, the green of the *Locusta viridissima* is wonderfully similar to that of the herbage amongst which it lives, and those species that frequent more arid spots are protected in the same manner. Yet many species have brilliantly coloured markings (though scarcely so in English forms), and during flight are almost as conspicuous as butterflies, but when settled it is nearly impossible to detect them, even although the spot where they dropped may have been carefully marked, and they rise again almost under the feet of the observer. Those that belong to the *Acyrididae* mostly lay their eggs in more or less cylindrical masses, surrounded by a glutinous secretion, in the ground. Some of the *Locustidae* also lay their eggs in the ground, but others deposit them in fissures in trees and low plants, in which the female is aided by a long flattened ovipositor, or process at the extremity of the abdomen, whereas in the *Acyrididae* there is only an apparatus of valves. The stridulation or "song" is mainly produced by friction of the hind legs against portions of the wing or wing-coverts, but variation exists in the exact method. To a practised ear it is perhaps possible to distinguish the "song" of even closely allied species, and some are said to produce a sound differing by day and night. The British species are not numerous, but in some parts of the world (and even in Europe) their numbers are very great, both in species and individuals.

GRATIANUS, AUGURUS (359–383), Roman emperor, son of Valentinianus I., was born in 359. In the ninth year of his age he received from his father the title of Augustus, but on his father's death in 375 he was compelled to share the Western empire with his infant brother, Valentinianus II., of whom he was appointed guardian, while his uncle Valens ruled over the Eastern empire. In 378 he gained a victory over the Alcmanni near the site of the present town of Colmar. Through the death of Valens in the same year, then devolved upon him the government of the Eastern empire, but feeling himself unable to resist the incursions of the barbarians, he ceded it to Theodosius, January 19, 379. For some years Gratianus conducted the government of his empire with energy and success, but gradually he sank into indolence and occupied himself chiefly with the pleasures of the chase. By adopting as the guards of his person a body of the Alam, and appearing in public in the dress of a Scythian warrior, he awakened the contempt and resentment of his Roman troops. A Roman named Maximus took advantage of this feeling to raise the standard of revolt in Britain, and invaded Gaul with a large army, upon which Gratianus, who was then in Paris, being deserted by his troops, fled to Lyons, where, through the treachery of the governor, he was delivered over to one of the rebel generals and assassinated, August 25, 383.

GRATIANUS, FRANCISCUS, compiler of the *Concordia discordantium Canonum* or *Decretum Gratiani*, and founder of the science of canon law, was born about the end of the 11th century at Chiusi in Tuscany, or, according to another account, at Cambray near Orvieto. In early life he appears to have been received into the Camaldulan monastery of Classe near Ravenna, whence he afterwards removed to that of San Felice in Bologna, where he spent many years in the preparation of the *Concordia*. The precise date of this important work cannot be ascertained, but it contains references to the decisions of the Lateran council of 1139, and the statement is vouched for by tolerably good authority that it was completed while Pope Alexander III. was still simply professor of theology at Bologna, — in other words, prior to 1150. The labours of Gratian are said to have been rewarded with the bishopric of Chiusi, but if so he appears never to have been consecrated, at least his name is not to be found in any authentic list of those who have occupied that see. The year of his death is unknown.

For some account of the *Decretum Gratiani* and its history see CANON LAW. The latest edition is that of Huillard (*Comptus des Leçons*, 1870). Compare Schulte, *Zur Geschichte des Literatur über das Decret Gratiani* (1870), *Die Glossen zum Decret Gratiani* (1872), and *Geschichte der Quellen und Literatur des Kanonischen Rechts* (1875).

GRATIUS FALISCUS, a Roman poet, contemporary with Virgil and Ovid, and author of a poem on hunting (*Cynegetica*), of which somewhat more than 636 lines have been preserved. Of his personal history nothing is known, but it has been doubtfully conjectured from his cognomen that he was a native of Falernum. The only reference to him to be met with in any writer of antiquity (Ovid, *Pont.*, iv, 16, 33) is of the most incidental kind, and his poem seems very early to have fallen into comparative oblivion. Our knowledge of it is derived chiefly from a manuscript of the 10th century, preserved at Vienna, but partly also from one of nearly the same age at Paris. It describes, somewhat after the manner of Xenophon, various kinds of game, the means to be employed for their pursuit and capture, the best breeds of horses and dogs, and in doing so it seldom rises above the dull level of the driest technicality, although occasionally there are faint reminiscences of Virgil.

The *edisse primigena* of this author was published in Venice in 1584, his work was also included by Gualter (1645–56) and Haugk (1728) in their editions of *Acta et Res Feronenses*, as well as by

Burman (1781) and Weinsdorf (1780) in the *Poeta Latina Minore*, and by Weber in the *Corpus Poetae usque ad Antonium*. The most recent editions are those of Stein (1832) and Haupt (1838). A rendering into English verse was published by Christopher Wase in 1864; this is also a German translation by Fohst (1869).

GRATTAN, HENRY (1746-1820), Irish statesman and orator, was born 3d July 1746. His father, a Protestant, was for many years recorder of the city of Dublin, and from 1761 to 1766 its representative in the Irish parliament, and his mother was a daughter of Thomas Massey, chief justice of Ireland. Both at school and at Trinity College, Dublin, which he entered in 1763, young Grattan greatly distinguished himself, especially in the study of the classics, and several well-authenticated anecdotes indicate also that the more prominent moral characteristics displayed in his public career had begun to assert their strength at a very early period. While still attending the university he discarded the Tory principles of his father, who, dying in 1766 before his imitation had time to moderate, testified his resentment by depriving him of the paternal mansion, and of all property not secured by settlement. Having inherited, however, a small inalienable patrimony he resolved to study for the bar, and in 1767 he entered the Middle Temple, London. He was called to the Irish bar in 1772, but never obtained a large practice, and indeed from the time that he left the university he seems to have concentrated his attention chiefly on politics and the study of popular oratory. He early acquired a passionate admiration of the great orators of Greece and Rome, and while in London he spent the most of his evenings in the galleries of the House of Commons or at the bar of the Lords, anxious to profit by every opportunity of obtaining an insight into the art of eloquence, his enthusiasm for which had received additional stimulus from the genius of Lord Chatham. Of the eloquence of Chatham he has given a detailed and graphic description in one of his letters, and he also wrote an admirable portraiture of his character, which was inserted as a note in the political publication *Baratavia* conducted by Sir Hercules Langrishe. The knowledge obtained from the study of the best specimens of ancient and modern oratory, and that gained from witnessing the debates in the English parliament, Grattan began sedulously to apply to the purposes of his own discipline. By the constant practice of recitation to imaginary audiences, and by taking part frequently in private theatricals, he succeeded in overcoming to a remarkable extent his great physical defects, so as to acquire a clear and rounded articulation, an emphasis in some respects admirably consonant with his meaning, and a certain ease in a style of elocution which was effective partly by reason of its very singularity. At the same time, by practising the habit of writing out the principal passages of his speeches, and subjecting them to a constant mental revision, he attained to the possession of a diction which for clearness, epigrammatic vigour, polished beauty of phrase, and the power of illuminating a whole subject by sudden flashes of meaning conveyed in a single sentence, is unsurpassed in modern oratory. He was equally diligent also in perfecting his political knowledge by a careful study of the history and political constitution both of ancient and modern nations, and the minor accomplishment of proficiency as a pistol shot, at that time essential to every Irish politician who would be prepared for all emergencies, was cultivated by him with the same dogged perseverance which he displayed in other matters.

When therefore, under the auspices of Lord Charlemont, Grattan in 1775 entered the Irish parliament, he had already all his powers under full command, and had so trained and disciplined his natural genius that it was able to exert its influence with untrammelled freedom. The period at which he began public life was one of the

most critical in his country's history, and it is within the limits of strict truth to affirm that he inaugurated a new era in his political condition, and that, whether for good or for evil, and whether by the direct success of his efforts or by the modifying or opposing influences they called into exercise, he has had a greater share than any other individual in determining her present relation to the United Kingdom. Through the writings of Molyneux and Swift, the beginnings of a true national sentiment had been previously awakened, and the first step in the path of constitutional reform had been taken, when by the advocacy of Flood the Octennial Bill of 1768 was passed, which limited the duration of parliaments to eight years, instead of as formerly making their continuance depend upon the life of the sovereign, but Flood himself—whose friendship and influence were a powerful element in determining Grattan to adopt a political career—had, like less formidable agitators, succumbed to the intrigues of the "castle," and, although possessed of a private fortune which placed him beyond the suspicion of being governed chiefly by mercenary considerations, had consented to hamper his political action by accepting a sinecure office, and it seemed as if the germs of a better future had already begun to rot in a soil of such political corruption. The difficulty of the task which Grattan had set before him was also increased by a peculiarity in the case of Ireland which requires to be emphasized. Her political constitution, and, with the exception of the restrictions which paralysed her trade, the laws which were inflicting upon her such moral and physical misery, did not nominally differ to any great extent from those of the country by which she was in reality governed. She possessed intact her separate nationality, she was blessed with the boon of a national parliament, she had a legal administration of her own, including the right of trial by jury, and she enjoyed something resembling the privileges of municipal government. She possessed these things, however, scarcely more than in form, and she possessed them in such a form that, instead of being the guarantee of her liberty, they increased her sense of bondage, and directly fostered discontent and chronic mutiny. Though the Test Act and the penal laws were actually enforced with less rigour than in England, yet from the numbers who came within their sweep their dissensions influence was incalculably increased. They excluded four-fifths of her otherwise eligible population from the jury box and from municipal and parliamentary suffrage, they had produced confiscations on almost a national scale with all the evils consequent on absenteeism, and from their operation there had resulted an ignorance, a poverty, a violation of the rights of conscience, not confined to a few thousands, helplessly dispersed throughout the kingdom, but affecting the great mass of the people, and both by their direct and their reflex action poisoning the springs of the whole national life. Her judges besides were liable to dismissal at pleasure, and her parliament had no independent authority, and by its very constitution was subject to corrupt influences far exceeding those in operation in the English parliament, and such as virtually to deprive it of independence of vote, almost as completely as it had been deprived of the power of legislation. Still that parliament constituted a kind of centre for political discussion and for the propagation and diffusion of political ideas, and it was by means of it that Grattan and his associates determined to work out the political and social regeneration of their country. Almost as soon as he entered parliament, Grattan became the acknowledged leader of the opposition, not only from the influence exerted by his oratory within the House, but from its power to kindle the enthusiasm of the people, and to create out of the chaos of shapeless and discordant elements the united sympathy and purpose of a true

national life. In this he received an assistance from external events which was embarrassing as well as helpful. From the American rebellion, which was the result of a struggle for rights similar to those he was contending for, from the war with France, which led to the creation of a volunteer army in Ireland that became a kind of political convention, and ultimately from the French Revolution, which in Ireland, more than in any other country of Europe, aroused wild desires after political freedom.

In February 1778 Grattan moved an address to the crown, to the effect that the condition of Ireland was no longer endurable, and although the motion was supported by only a small minority, the discussion bore fruit in the same year by the concession of free export of all produce except woolens, and by the modification of the penal laws to the extent of allowing the Catholics to hold leases for 999 years. In the following year the volunteers by their determined attitude crowned with success his efforts, along with Flood and Durlagh, to effect the total repeal of the restriction Acts, and the same year saw also the repeal of the Test Act. With a view to increase and take advantage of the rising tide of national sentiment, Grattan on April 19th 1780 moved his famous resolutions that the "king with the consent of the parliament of Ireland was alone competent to enact laws to bind Ireland, and that Great Britain and Ireland were indissolubly united, but only under a common sovereign," but so satisfied was he with the tone of the debate that, unwilling needlessly to irritate or embarrass the English Government, he did not press his motion to a division. An agitation was, however, begun in the following year against Poyning's Act and the Mutiny Act, and Grattan besides supported the introduction of a bill permitting the Catholics to inherit and hold property on the same terms as other subjects. In order also to bring pressure to bear on the English Government, Grattan, Flood, and Charlemont met privately in the beginning of 1782, and drew up for the consideration of the volunteers' delegates two resolutions in reference to independence, and to these Grattan, on his own responsibility and without the knowledge of Flood and Charlemont, added a third in favour of the measure for the relaxation of the penal laws against the Catholics. All these resolutions were adopted by the delegates unanimously, and Grattan, strong in armed support, repeated his motion for a declaration of independence, which, although it was lost, aroused such general enthusiasm that, when on the 16th April he rose to move a Declaration of Rights, he in a brilliant oration congratulated his hearers and his country on the triumphant issue of the struggle, his first words being—"I am now about to address a free people." So completely did his eloquence rise to what was deemed the greatness of the occasion that its effect has seldom been equalled in the annals of oratory, and in the state of high-wrought excitement that prevailed, the Government, then doubtful as to the result of the siege of Gibraltar by the French and Spaniards, did not dare to refuse the boon which had already been in reality appropriated without their permission, and on the 17th May resolutions were passed unanimously, pledging the English parliament to redress the grievances complained of. In recognition of Grattan's services the Irish parliament was prepared to have voted him a grant of £100,000, but he was with difficulty persuaded to accept half that sum, and, although only agreed to do so from the consideration that, by relieving him from the necessity of practising at the bar, it would enable him to devote the whole of his energies to politics. He determined, however, that this gift should not in any way bias his political action, and when Flood, supported by the volunteer convention, brought forward his motion for repeal, he at the expense of his popularity moved its rejection—a procedure which also gave rise to an extraordinary scene of

mutual reanimation between the two orators. For the next ten years Grattan carried on the struggle for the reform of Irish abuses with almost no success, and his Place and Pension Bill, and bills to make the great officers of government responsible for their proceedings, to prevent revenue officers from voting at elections, and to abolish ecclesiastical tithes, were all rejected. Pitt, at one time disposed to promote emancipation, became lukewarm in his zeal after the rejection in 1788 of Mr Orde's bill for the removal of trade restrictions, which, on account of a clause binding the parliament to re-enact England's navigation laws, was opposed by Grattan as involving a principle that implied a revocation of the constitution, nor did the action of the Irish parliament in the regency dispute of 1789 tend to smooth the relations between the two countries. At last in 1793 parliamentary suffrage was conceded to the Catholics as a sop to the fury of the United Irishmen, but the concession served only to whet the appetite for further redress, and when the hope of obtaining this, after reaching the verge of certainty by the appointment of Fitzwilliam as lord-lieutenant, was suddenly dashed by his recall, the spirit of brooding discontent increased until ultimately it resulted in the bloody rebellion of 1798. Previous to its occurrence Grattan had withdrawn from parliament. It has been surmised by Mr. Froude that in taking on the question of emancipation Grattan wished to effect a complete separation from England, and perhaps calculated, though a Protestant, on obtaining as the reward of his services the first place in the new commonwealth, but besides that the conjecture is unnecessary, since it was quite a possible supposition that emancipation might have proved the best method of confirming the loyalty of the Catholics,—and it was most certainly a better method than union without emancipation,—it is without a shadow of proof to suppose it, and would also have implied teachery on his part of the blackest kind, while teachery of any kind is barred by the whole course of his political life. In 1798 Grattan, though in feeble health, entered the Irish parliament as member for Wicklow, specially to oppose the motion for union, a measure whose bitterness was not rendered less distasteful to him from the time, manner, and means employed for its accomplishment. He regarded its success as almost the nullification of Ireland's partial freedom, and the indefinite postponement of the attempt to remedy her wrongs. Though knowing from the beginning that to contend against the influence of the Government was hopeless, he excited all his eloquence in condemnation of the measure, and his last words in the Irish Parliament were—"It will remain anchored here with fidelity to the fortunes of my country, faithful to her freedom, faithful to her fall." In the course of these debates Grattan was three times violently attacked by Mr. Corry, chancellor of the exchequer, but at last retaliated with overwhelming effect. In the duel which followed Corry was wounded.

After the Union Grattan withdrew for a time from public life, but, in order to lend his assistance to the passing of the Catholic Relief Bill, he in 1805 entered the English parliament as member for Malton, and in the following year he was returned by Dublin, which he had formerly represented in the Irish parliament. Although his speeches in the new arena did not detract from his fame, the union had effected so great a change in his standpoint that the inspiration which had formerly given to his eloquence such a glow of confident ardour, and had braced his powers to such supreme efforts, was no longer present. He refused to take office in the Fox ministry, but he nevertheless gave the Whigs his support on all important occasions, and by voting with the Government on the Irish Insurrection Bill of 1807, he showed that his regard for the general welfare of the empire was

unaffected by the great political disappointment of his life. After the rejection of the Catholic Relief Bill of 1813, which was accompanied by a clause reserving to the English sovereign the power of veto in the election of Catholic bishops, the Catholic board repudiated the proposed compromise and declined to entreat Giatian further with their cause. He, however, gave it the same energetic support as formerly, and after 1815 he never spoke in the English parliament on any other subject. In 1819 his motion was defeated by the small majority of two, and on the reassembling of parliament in the following May, he undertook, contrary to the advice of his physicians, a journey to London in order again to bring forward the subject, but died a few days after his arrival, 4th June 1820. He received the honours of a public funeral and a grave in Westminster Abbey, where he lies near the tombs of Pitt and Fox.

Lord Byron, who had heard Giatian only in the English House of Commons, says that he would have come near to his ideal of a perfect orator but for his halcyon manner, and he also states that Curran was in the habit of taking him off by bowing to the very ground and thanking God that he had no peculiarities of gesture or appearance. His features were large and plain, and he was low in stature and so awkwardly formed that probably he never could have acquired a very graceful gesture, but his gravity and impressiveness of his bearing banished all sense of the ridiculous, and perhaps even the oddness and violence of his attitudes assisted to dissipate the feeling in his hearers of his personal insignificance. His voice, though not harsh, was deficient both in mellowness and volume, and when not elevated by emotion into shrillness, had a low droning accent. He succeeded, however, by virtue of appropriate emphasis and of concentrated energy, in bringing home to his hearers all the various shades of the passion and purpose of his discourse, and this perhaps with greater vividness than if it had been accomplished by means of an elocution which, if less faulty, would not have expressed so well his own peculiar individuality. In private life he was simple, genial, and courteous, and the felicity of his language, favoured by an enunciation and manner that were all his own, lent to his conversation a rare and peculiar charm.

His speeches suffer much from imperfect reporting, but their leading characteristics can be determined with considerable accuracy. Great labour, direct and indirect, was bestowed on their preparation, and few speeches show so many traces of art, but it is at times transfused and palpitating with enthusiasm, and therefore, though defective in ease and simplicity, they cannot be charged with artificiality or affectation. In regard to the chief fault of his style—the excessive use of epigram,—it must be remembered that he made it supply the place both of wit and of direct argument, and that it never wearied his audience by a monotony of elated similes, but, by its incisive vigour and its startling originality, rendered his speeches perhaps unequalled for sustained brilliancy and interest. His oratorical triumphs were won, not by the stately marshalling of arguments and illustrations towards a climax, but by sudden surprises from so many directions, and so closely following each other that resistance to his attacks soon became impossible. In regard to subject-matter his speeches do not suffer from comparison even with those of Burke. His favourite method of enforcing his arguments was by illustrations either of similarity or of contrast drawn from history or from contemporary events, and while in this way he exhibited in every possible light the plausibility of his contentions, he gave dignity and elevation to his theme by removing it from the narrow sphere of party politics, and connecting it with principles of universal and permanent consequence. Much of the effect of his eloquence was due to the boldness of his

statements and of his allusions and imagery, a boldness which, though often amounting to harshness, never overstepped the boundaries between the sublime and the ridiculous. In remarkable contrast to other Irish orators, and especially to his great contemporary Curran, he possessed neither wit nor humour, and this no doubt accounts for the sustained and pitiless vehemence of his invectives against opponents who had thoroughly roused his anger. These attacks were rendered the more formidable from his power of delineating character by epithets, the graphic force of which had an almost electrical effect. This power he evinced, however, more frequently for purposes of laudation than censure, and perhaps the finest examples of it in his speeches are two short incidental allusions to Fox and Burke. A remarkable union of boldness with moderation and restraint characterized his statesmanship as it did his oratory, for while he embraced within his scheme of reform the whole circle of Ireland's wrongs and disabilities, and was prepared to face the consequences of all constitutional changes, however great, which justice seemed to demand, his unswerving aim, in the face both of strong provocation from the Government and of the powerful assaults of popular clamour, was not to loosen but to cement the ties which bound Ireland to Great Britain. That his political course was governed too much by abstractions, and had too little regard to expediency, is a conclusion to which has been both affirmed and denied, but in any case it will be admitted by most that his beneficial influence on Irish politics has been less felt by the direct accomplishment of his aims than through the moral effect of his enlightened and incorruptible patriotism, and the gradual change which has taken place in the mental attitude of English statesmen towards his country.

Giatian's Speeches, with prefatory observations, the whole comprising a brief review of the most important political history of Ireland were published at Dublin in 1811. His *Speeches in the Irish and in the Imperial Parliament*, edited by his son, in 4 volumes, appeared at London in 1822, and his *Miscellaneous Works* also in the same year. See his *Memories* by his son, Henry Giatian, Esq. M.P., in 5 volumes, London, 1889-96. *Lecky's Leader of Public Opinion in Ireland*, 2d edition, 1878, and, among various notices by contemporaries, especially that in vol. vii of the *Dublin University Magazine*, which, notwithstanding political bias, gives a remarkably unprejudiced representation of his character and abilities, and that by Lord Brougham in the 1st vol. of his collected works. The political events of the period are of course graphically narrated by Mr. Fionn in his *English in Ireland*, vols. ii and iii, but his principal design is to show the pernicious effects of Giatian's efforts. Among the vilest criticisms of Mr. Fionn's work is that by W. R. Lecky in *Miscellaneous Magazine* for January and June 1878.

GRATZ, or GRAZ, the capital of the Austrian crownland of Styria, is situated in the broad and fertile valley of the Mur, and the beauty of its position has given rise to the punning French description, *La ville des Graces au la revê de l'Amour*. From Vienna it is distant about 90 miles as the crow flies, and about 139 miles by rail. Its latitude is 47° 49' N., its longitude 15° 27' E., and its height above the sea 1499 feet. The main town lies on the left bank of the river, at the foot of the Schlossberg or castle-hill, but two of the principal suburbs, Lend and Gries, occupy an extensive area on the right bank, and communication is maintained by four bridges besides the railway bridge. Among the numerous churches of the city the most important is the Gothic cathedral of St. Stephen, founded by the emperor Frederick III. in 1450-1462, on the site of a previous church mentioned as early as 1137. It has been several times modified and redecorated, more particularly

¹ The name was frequently written Gratz, Grätz, or Gize, but in 1818 it was decided, through the influence mainly of Hammer Purgstall, that the official form should be Gize, in accordance as once with the local pronunciation and the derivation of the word, which was originally, it is believed, the Slavonic for "little castle," Gradišce or Grates in Serbian, and Hradek in Bohemian.

in 1718. The present copper spire dates from 1663. The interior, which measures 200 feet in length by 92 feet in breadth, is richly adorned with stained glass windows of modern date, costly shrines, paintings, and tombs. In the immediate neighbourhood of the cathedral is the mausoleum church of St Catherine's, erected by Ferdinand II. as a burial-place for himself and his family. It has an imposing façade with Corinthian columns, two cupolas, and a tower. Worthy of mention also are the church of the Sacred Blood, which has been the municipal church since 1585, and which possesses an altar-piece by Tintoretto; the Augustinian church, commonly called Stiegenkirche, appropriated to the service of the university since 1827; and the church of St Anthony of Padua, connected with the lunatic asylum, and popularly known as the Narrenturm. Besides the old imperial castle, formerly the residence of the Styrian princes, and now the seat of the statthalter, Gratz contains the palace of the prince-bishop of Seckau, the palace of Count Attem, with a fine picture-gallery, and the old palace of the archduke John, now in

Plan of Gratz.

possession of the counts of Meran. The sandhaus, where the estates hold their sittings, was erected in the 16th century; among its curiosities are the Styrian hat and the great silver cup called the *Landeshaubenbund*. The rathhaus, built by Stadler between 1802 and 1807, is of interest mainly for its collection of instruments of torture. At the head of the educational institutions is the university, founded in 1586 by Charles Francis, and restored in 1817 after an interruption of forty-five years. The old buildings dating from between 1573 and 1599 are being replaced by a fine modern erection. Of greater celebrity than the university is the Joanneum, originally instituted in 1811 by the archduke John Baptist as a national museum, but now developed into a complex organization for the higher education, with a regular professorate, a library of 60,000 volumes, archives peculiarly rich in Oriental MSS., a botanical garden, and other auxiliary departments. Mohs, Schrütten, and Unger are among the eminent names associated with its chairs. The Styrian hospital, founded in 1768, the town hospital, the civic hospital, the military

hospital, the children's hospital, and the lunatic asylum are among the principal benevolent institutions. An official money-lending establishment has been in existence since 1755. Of the minor institutions of various kinds which prove the prosperity of the town the list would be a long one. An active trade, fostered by abundant railway communication both with north and south, is combined with no small manufacturing industry in the departments of iron and steel wares, paper, chemicals, sugar, vinegar, liqueurs, watches, and mathematical instruments. Few towns are better supplied with public pleasure grounds and holiday resorts. The Schlossberg, which rises to 380 feet above the valley, was laid out by General Welden shortly after the destruction of the castle; and a great part of 43 acres has been made almost to encompass the inner city. The Calvarienberg lies in the north-west of the town; and not far off is the castle of Eggenberg. The population of Gratz, in spite of a high rate of mortality which prevailed for some time, amounted in 1869 to 81,119, exclusive of the garrison of 4000 men. In 1875 the total, civil and military, was estimated at 90,000.

History.—Gratz may possibly have been a Roman site, but the first mention of it under its present name is in a document of 881 A.D. Ottocar V. of Traungau chose it as his residence in 1050, and in 1163 it is designated for the first time the *Landesherrliche Stadt*. Its privileges were confirmed by King Rudolf in 1281. Surrounded with walls and fosses in 1431, it was able to defend itself against the Hungarians under Matthias Corvinus, who attempted to get possession of his promised bride at refuge within. In 1529 and 1632 the Turks attacked it with as little success. As early as 1559 the Lutheran doctrine was preached in Gratz by Seiffied and Jacob von Eggenberg, and in 1540 Eggenberg founded the Paradise or Lutheran school in which Kepler afterwards taught. But Charles II. burned 20,000 Protestant books in the square of the present lunatic asylum, and succeeded by his oppressive measures in bringing the city again under the authority of Rome. New fortifications were constructed in the end of the 16th century by Franz von Poppondorf, and in 1644 the town afforded an asylum to the family of Ferdinand III. The town was in possession of the place in 1797 and again in 1805; and in 1809 Marshal MacDonald, having in terms of the peace of Vienna entered the citadel which he had vainly besieged, blew it all up with the exception of the bell-tower and the citizens' or clock tower. See Banditsch, *Topographische Kunde der Hauptstadt Grätz*, 1808; Pöschner, *Grätz und seine Umgebungen*, Grätz, 1857; Buland, *Geschichte der merkwürdigsten Begebenheiten in Grätz*, Grätz, 1848; Schmalzer, *Historisch-topographische Geschichte der Stadt Grätz und seiner Umgebungen*, Grätz, 1846; Weidmann, *Wien, Pöschner's Führer durch Grätz*, 1849; Iwer and Peters, *Grätz: Geschichte und Topographie*, Grätz, 1876.

GRAUBÜNDEN. See GAZONS.

GRAUDENZ (Polish *Grudziądz*), a town of Prussia, chief town of a circle in the province of West Prussia, government district of Marienwerder, is situated on the right bank of the Vistula, which is here crossed by railway bridge, 18 miles S.S.W. of Marienwerder and 40 miles N.N.E. of Thorn. It has a Protestant and a Catholic church, a garrison church, two synagogues, a royal gymnasium, a Catholic normal school, an Evangelical normal school, a city school of the middle grade, a higher female school, three hospitals, three orphanages, and a reformatory. The industries include ironfounding, brewing, dyeing, wool-spinning, and the manufacture of tapestry, cigars, shoes, and brushes. The population of the town in 1875 was 14,522, and including the fortress, 16,615.

Grudenz was founded about 1220, and received town rights in 1291. At the peace of Thorn in 1465 it came under the lordship of Poland. From 1655 to 1759 it was held by Sweden, and in 1772 it came into the possession of Prussia. The fortress of Grudenz, which since 1878 has been used merely as a barracks and military depot and prison, is situated on a steep eminence about 1½ miles north of the town and outside its limits. It was completed by Frederick the Great in 1776, and has been rendered famous through its defence by Courbières against the French in 1807.

GRAUN, CARL HANNAK (1701–1759), a celebrated composer, was born May 7, 1701, at Vahrenbrock in Saxony, the youngest of three brothers, all more or less musical. His father held a small post under Government, but he gave his children a careful education. Graun's

beautiful soprano voice was noticed at the school where he was educated, and soon secured him an appointment in the choir of the city of Dresden. His masters were Gündig and Petzold, and at an early age he composed a number of sacred cantatas and other pieces for the church service. He completed his studies under Schmidt, and profited much by the Italian operas which were performed at Dresden under Lotti, the celebrated composer. After his voice had changed to a tenor, he made his debut at the opera of Brunswick, in a work by Schürmann, an inferior composer of the day, but not being satisfied with the airs assigned him he re-wrote them, so much to the satisfaction of the court that he was commissioned to write an opera for the next season. This work, *Pollidoro* (1736), and five other operas written for Brunswick, spend his fame all over Germany. Other works, mostly of a sacred character, including two settings of the *Psalms*, also belong to the Brunswick period. It was there that Frederick the Great, at that time crown prince of Prussia, heard the singer, and immediately engaged him for his private chapel at Castle Ransberg.

There Graun remained for five years, and wrote a number of cantatas, mostly to words written by Picander himself in French, and translated into Italian by Boldarelli. On his accession to the throne in 1740, Frederick sent Graun to Italy to engage singers for a new opera to be established at Berlin. Graun remained a year on his travels, earning universal applause as a singer in the chief cities of Italy. After his return to Berlin he was appointed royal chapel-master, with a salary of 2000 thalers (£800). In this capacity he wrote twenty-eight operas, all to Italian words, of which the last, *Merope* (1765), is perhaps the most perfect. But of infinitely greater importance than these is his oratorio *Death of Jesus*, which is still annually performed at Berlin. It is here that Graun shows his skill as a contrapuntist, and his originality of melodious invention. In the Italian operas he imitates the florid style of his time, but these also considerable dramatic power is occasionally shown in the recitatives. Graun died on the 8th of August 1759, at Berlin, in the same house in which, thirty-two years later, Meyerbeer was born.

GRAVELINES (Flemish *Gravelinghe*, German *Gravelingen*), a fortified seaport town of France, in the department of Nord and arrondissement of Dunkirk, is situated near the mouth of the Aa, 11 miles S.W. of Dunkirk. The principal buildings are the church of the town, the magazine, and the town hall. The harbour is only accessible at flood tide, but there is a considerable shipping trade in fish, apples, vegetables, and eggs. Shipbuilding is also carried on, and there are salt refineries, sail and linen manufactories, saw mills and meal mills. The fortifications were constructed anew by Vauban in the reign of Louis XIV. For its defence the land, to the distance of a mile all round, can be laid under water at pleasure. The population in 1876 was 4182.

Gravelines was formed in 1160 by Count Thierry of Flanders, was conquered by the English in 1385, and came into the possession of the duke of Burgundy in 1405. It is celebrated for the victory gained by the Spanish under Segmont over the French under Marshal de Thermes, 18th July 1568. It was taken by the duke of Orleans in 1544, taken by Archduke Leopold in 1668, and again taken by the French under Vauban in 1668, after which it was ceded to France by the treaty of the Pyrenees in 1669.

GRAVESEND, a municipal and parliamentary borough, river port, and market-town in the county of Kent, England, is situated on the right bank of the Thames opposite Tilbury Fort, 30 miles below London by the river, and 24 miles by rail. It extends about 2 miles along the river bank, occupying a slight acclivity which reaches its summit at Windmill Hill, whence extensive views are obtained of the river, with its windings and shipping. The older and lower part of the town is irregularly built, with narrow

and inconvenient streets, but the upper and newer portion contains several handsome streets, squares, and terraces. Gravesend is the boundary of the port of London. It has three piers, the town pier, erected in 1836, and belonging to the corporation, the fairtime pier, built about 1840, and a new pier and station lately erected by the London, Tilbury, and Southend Railway Company. The town is a favourite resort of the inhabitants of London, both for excursions and as a summer residence. The principal buildings are the town-hall, a neat and conspicuous Doric edifice erected in 1836, the parish church of Gravesend, erected on the site of an ancient building destroyed by fire in 1727, Milton parish church, in the Late Decorated style, erected in the time of Edward II, the county courts, the clubhouse of the Royal Thames Yacht Club, the convalescent-house, the assembly rooms, the workmen's hall, the free grammar school, the almshouses for aged persons, and the dispensary and infirmary. East of the town are the earthworks designed to assist Tilbury Fort in obstructing the passage of an enemy's force. They were originally constructed on Vauban's system in the reign of Charles II, and some years ago they were strengthened at the cost of nearly £150,000. Gravesend has some important trade in coal and timber, and fishing, especially of shrimps, is carried on extensively. The principal other industries are boat building, nonfounding, brewing, and soap-boiling. Fruit and vegetables are largely grown in the neighbourhood for the London market. Since 1867 Gravesend has returned a member to parliament. The municipal borough includes the parishes of Gravesend and Milton. The population of the municipal borough in 1871 was 21,365, and of the parliamentary 27,493.

Gravesend occurs in Domesday Book under the name *Gravelhem*. It was burnt by the French in 1377. In 1573 it obtained a charter of incorporation from Queen Elizabeth, who also gave the right, first granted by Richard II, of regulating the "Long Ferry" (a passage from London) and granting a fee from the "wages, tolls, light housemen (nobles), and wharves" on the river.

GRAVINA, a city of Italy, in the province of Bari, is situated on a hill to the left of the river Gravina, 7 miles from Altamura, and 37 S.W. of Bari. It is surrounded by tower-flanked walls, and has a cathedral, and a castle which belongs to the Orsini family, of which the eldest branch still keeps the title of duke of Gravina. A great cattle fair is held in the town on April 20, a fine breed of horses is raised in the neighbourhood, nitre is collected from the tufa rock of the district, and cheese, macaroni, and other ware are manufactured. Population in 1871, 14,194.

GRAVINA, GIOVANNI VINCENZO (1664-1718), an Italian litterateur and jurisconsult, was born at Roggiano, a small town near Cosenza in Calabria, January 20, 1664. He was descended from a distinguished family, and under the direction of his maternal uncle, Gregorio Caloprese, who possessed some reputation as a poet and philosopher, received a learned education, after which he studied at Naples civil and canon law. In 1689 he came to Rome, where in 1695 he united with several others of literary tastes in forming the Academy of Arcadians. A schism occurred in the academy in 1711, and Gravina and his followers founded in opposition to it the Academy of Quirina. From Innocent XII Gravina received the offer of various ecclesiastical honours, but declined them from a disinclination to enter the clerical profession. In 1699 he was appointed to the chair of civil law in the college of La Sapienza, and in 1708 he was transferred to the chair of canon law. He died at Rome January 6, 1718. He was the adoptive father of Metastasio.

Gravina is the author of a number of works of great erudition, the principal being his *Orsines Jus Civile*, completed in 8 vols. in 1718, and his *De Romanis Imperiis*, 1712. A French translation of the former appeared in 1775, of which a second edition was published in 1829. His collected works were published at Leipzig in 1787, and at Naples, with notes by Mascovius, in 1788.

GRAVITATION

I GRAVITATION AT THE SURFACE OF THE EARTH

It is a matter of universal experience all over the earth that a heavy body tends to fall to the ground. Let us inquire into this in the first place by taking such a general view of the phenomenon as would be presented to an imaginary spectator who was sufficiently removed from the earth to be able to take a general view.

Fig 1 represents a section of the earth by a plane which is drawn through its centre O. Then, the earth being sufficiently near a sphere for our purpose, we may regard the section PQRS as a circle, where the points P, Q, R, S are the intersections of the lines OA, OB, OC, OD with the surface of the earth. If a stone be dropped from a point A above the surface of the earth, it will fall to the ground at P. The spectator would also notice that, if a stone were dropped from B or C or D, it would fall up in the ground at the points Q, R, S respectively. From A the stone would appear to fall downwards, from C it appears to move upwards, from B the spectator would see the stone moving to the left, while from D it appears to move to the right. One feature of these motions could not fail to be noticed: they all tend to the centre of the earth. The spectator might therefore sum up his experience in the following statement—

A body dropped from a point above the surface of the earth always falls in a straight line which is directed towards the centre of the earth.

Fig 1

§ 1. *Attraction*.—The familiar instance of the action of a magnet upon a piece of iron will suffice to illustrate what is meant by the word *attraction*. In virtue of certain properties possessed by the iron and the magnet, they are drawn together. The magnet draws the iron, and the iron draws the magnet. This particular kind of attraction is of a very special character. Thus, for example, the magnet appears to have no appreciable influence on a piece of wood or a sheet of paper, and has indeed no considerable influence on any known substance except iron.

By the attraction of gravitation, every body attracts every other body, *whatever is the material of which each is composed*. In this we see a wide difference between the attractions of gravitation and that form of attraction which is known as magnetic attraction. Nor is the contrast between the *intensities* of these two different attractions less striking. The keeper of a magnet is drawn to the magnet by two different forces of attraction. The first of these is the gravitational attraction, which, so far as we know at present, would be equally exerted, whether the magnetism were present or not. The second is the magnetic attraction. The latter is enormously greater than the former, in fact, under ordinary circumstances as to intensity and dimensions, the intensity of the attraction of gravitation will not be nearly so much as a millionth part of the magnetic attraction.

The intensity of the attraction of gravitation is indeed so small that, with one conspicuous exception, we can only become aware of its existence by refined and elaborate inquiries. That any two objects—for example, two books lying on the table—do actually attract each other, there can be no doubt whatever, but the intensity of this is so small that the attractive force cannot overcome the friction of the

table, and consequently we do not find that the books are drawn together. It has, however, been found that the intensity of the attraction of gravitation between two masses is directly proportional to the product of those masses. Hence though the force is so small as to be almost unappreciable between two bodies of moderate dimensions, yet when the masses of the two bodies, or of even one of them, are enormously great, the intensity of the force will be sufficiently large to be readily discernible. In this way it is that the existence of the attraction of gravitation has been made known to us, and is, in fact, identified with our daily experience,—indeed, with our actual existence. The mass of the earth is so enormous that the attraction of gravitation which exists between it and an object near the surface is readily appreciable. It is this attraction of gravitation between the earth and any object which constitutes that force which is referred to when we speak of the *weight* of the body. It is the attraction of gravitation which causes bodies to fall to the surface of the earth, and it is only to show that the facts already presented with respect to the direction in which a falling body moves are readily explained by the supposition that the motions are due to an attractive influence exerted by the earth, or, to speak more correctly, to a mutual attraction subsisting between the earth and the body.

Let O be the centre of the earth, supposed to be a sphere, and let A be the position of a body above its surface. Then, when the body is released, the attraction must evidently cause the body to move along the line OA. The line OA, in fact, is directed along a diameter of the sphere, and there is really no reason why the stone should move to one side of the line more than to another. We thus see that attraction would always tend to draw objects in a direction pointing towards the centre of the earth. The observed facts are therefore explained by the supposition that the earth possesses a power of attraction.

§ 2. *Movement of a Falling Body*.—Our knowledge of the force of gravitation being ultimately founded on observation and experiment, it will be convenient at this point to describe the experiments by which a knowledge of the laws of motion of a falling body may be ascertained. We shall first describe these experiments, and then we shall discuss the laws to which we are conducted by their aid.

A beginner is apt to be surprised when he is told that a heavy body and a light body will fall to the ground in the same time if let drop from the same height. Yet nothing can be easier than to prove this important fact experimentally. Take a piece of cork in one hand and a bullet in the other, and drop these two objects at the same moment from the same height. They will reach the ground together. Nor will the results be different if we try a stone and a piece of wood. If, however, one of the objects were a feather and the other were a stone, then no doubt the latter would reach the ground long before the former. But this arises from a cause quite different from gravity. It is the resistance of the air which retards the motion of the feather. Even the stone is retarded to a certain extent by the resistance of the air, but the feather, on account of its greater surface in proportion to its mass, is much more retarded. If we could get rid of the influence of the air, the stone and the feather would be found to fall to the ground in the same time. This can actually be verified by performing the experiment (on a similar one) in a space from which the greater portion of the air has been withdrawn by the aid of an air-pump. But the same thing can also be shown in a much more simple manner.

Lay a small flat feather upon the top of a penny piece held horizontally. Then let the penny fall, it will be followed with equal rapidity by the feather, which will be found to remain in contact with the penny throughout the entire descent. In this case the penny piece displaces the air, and thus to a great extent shields the feather from the resistance to which it would be exposed without such protection; it is thus found that the two objects fall to the ground from the same height at the same time.

The various experiments to which we have referred suffice to establish the very important result that *the time occupied by a body in falling to the surface of the earth, if dropped from a point above it, is independent of the mass of the body as well as of the materials of which the body is composed.*

There are, no doubt, certain apparent exceptions to the generality of this statement. The law, as we have stated it, does surely not apply to the case of a balloon or a live bird. In each of these cases the air is made, directly or indirectly, to supply a force which overcomes the force of gravity and neutralizes its effects, but *if there were no air*, then the balloon and the bird would fall to the ground in precisely the same time as a 56 lb weight would do when dropped from the same height. It will not be necessary for us to introduce any further reference to the resistance of the air, and we shall discuss the phenomena presented by falling bodies as they would occur in a space from which the air has been removed.

We have by these considerations cleared the way for a very important quantitative determination. Taking a given interval of time,—for example, one second,—we see that the height through which a heavy body will fall in one second depends neither upon the mass of the body nor on the materials of which it is composed. This is therefore a constant at any given place on the earth's surface for every description of body, and it is of fundamental importance to determine that quantity accurately. By an indirect method, founded on pendulum observations, it is possible to determine this quantity with far greater accuracy than would be attainable by actually making the experiment. The value as thus found is slightly different at different parts of the earth though constant at each one. At any part of the United Kingdom it may be taken as 161 feet.

When the distance which the falling body moves over in the first second has been ascertained, it is possible to find the distance which will be accomplished in two seconds, or indeed in any number. The difficulty of the question arises from the circumstance that, as the velocity of the falling body is gradually increasing, the distance moved over in the second second is greater than it was in the first, and generally that the distance in any second is greater than the distance accomplished in any previous second. Imagine the "lift" in a hotel to be a room 161 feet high, then when the lift is at rest, a stone will take one second to fall from the top of the room to the floor. But now suppose the experiment to be repeated, when the lift is either ascending or descending. It will be found that no matter what the velocity of the lift, provided it remains uniform for a second, and no matter whether the lift be ascending or descending, the stone will still take exactly one second to fall from the ceiling to the floor.

To illustrate the important conclusions which can be drawn from this experiment, let us make some suppositions with reference to the velocity of the lift. Suppose that the lift is descending with a velocity of 5 feet per second. Then since it is found that the stone will reach the floor in one second, it is manifest that during that second the stone must actually have fallen through a distance equal to the height of the room augmented by the 5 feet through which the floor of the room has descended. The total dis-

tance traversed by the stone is therefore $161 + 5 = 211$ feet. It is, however, to be observed that at starting the stone must necessarily have had the same velocity as the lift, i.e., 5 feet per second. The observed facts can therefore be explained by supposing that the stone actually started with a velocity of 5 feet per second, and that gravity acted upon the stone so as to draw it 161 feet nearer the earth than it would have been had gravity not acted. On the other hand, suppose that at the time when the experiment was made the lift was ascending with an uniform velocity of 5 feet per second. Then the actual distance travelled by the stone in falling will be less than the height of the ceiling by the distance through which the floor has been raised, i.e., $161 - 5 = 156$ feet. Observation nevertheless shows that the time occupied in falling from the ceiling to the floor is still one second. This observed fact can be explained by remembering that at the moment of starting, the stone must actually have had the same velocity as the lift, i.e., an upward velocity of 5 feet per second. If therefore gravity had not acted, the stone would in one second have ascended through a vertical distance of 5 feet. The observations are therefore explained by supposing that gravity in this case also draws the body 161 feet nearer the earth in one second than the body would have been had gravity not acted.

By suitably contrivances it is possible to ascertain that a body dropped from rest will in a time of two seconds move over a space of 644 feet. We have already seen that during the first second the body will fall 161 feet. It follows that in the second second the space described by a body falling freely from rest is $644 - 161 = 483$. It is thus obvious that the space described in the second second is three times as great as the space described in the first second. To what is this difference to be ascribed? At the commencement of the first second the body was at rest, at the conclusion of the first second the body had attained a certain velocity, and with this velocity the body commenced its motion during the second second. The total distance of 483 feet accomplished during the second second is partly due to the velocity possessed by the body at the commencement, and partly to the action of gravity during that second. By the principle just explained, we are able to discriminate the amounts due to each cause. It appears, from the experiments already referred to, that during the second second as during the first the effect of gravity is simply to make the body 161 feet nearer the earth than it could otherwise have been. But the body moves altogether 483 feet in the second second, and as the action of gravity during that second will only account for 161 feet, it follows that the residue, amounting to $483 - 161 = 322$ feet, must be attributed to the velocity accumulated during the first second.

We are therefore led to the very important result that a body falling freely from rest in the United Kingdom will have acquired a velocity of 322 feet per second when one second has elapsed. It need not be a matter for surprise that, though at the close of the first second the velocity acquired is 322, the distance moved over during that second is only 161. It will be remembered that the body starts from rest, and that while in the act of falling its velocity is gradually increasing. The body, therefore, moves much further in the last half of the second than it did in the first half, and consequently the total distance travelled must be less than the distance which would have been accomplished had the body been moving during the whole second with the velocity acquired at its termination.

It might not be easy to arrange a direct experiment to show how far the body will fall during the third second, we can, however, deduce the result by reasoning from what we have already learned. Let us suppose that the lift

already referred to is descending with an uniform velocity of 32.2 feet per second. A body let drop from the ceiling during the motion, will, as before, reach the floor in one second. The body will therefore have acquired, *relatively to the moving lift*, a velocity of 32.2 feet per second. But the lift is itself in motion with a velocity of 32.2 feet per second. The *actual velocity* of the body must be measured by its velocity *relatively to the lift*, added to the velocity of the lift itself. It therefore appears that the body which, when it commenced to fall, had a velocity of 32.2 feet per second, acquires an equal amount during its fall, so that at its close the body actually had a velocity of $32.2 + 32.2 = 64.4$ feet per second. A body falling freely from rest acquires a velocity of 32.2 feet in the first second, it follows that at the close of the first second the body is in the same condition as if it were let fall from the ceiling of the lift, under the circumstances just described. The motion during the third second is therefore commenced with the velocity of 64.4 feet, and in consequence of this initial velocity alone a distance of 64.4 feet will be accomplished in the third second. To this must be added 16.1 feet, being the additional distance due to the action of gravity, and therefore we have for the distance through which a body falling freely from rest will move in the third second, $64.4 + 16.1 = 80.5$. Similar reasoning will show that the velocity acquired at the close of the third second is $64.4 + 32.2 = 96.6$. With this velocity the fourth second is commenced and therefore the distance accomplished during the fourth second is $96.6 + 16.1 = 112.7$.

The results at which we have arrived may be summarily stated in the following propositions—

A body falling freely from rest acquires a velocity which is equal to the product of 32.2 and the number of seconds during which the motion has lasted.

A body falling freely from rest moves over spaces proportional to the consecutive odd numbers (1, 3, 5, 7, &c) in each of the consecutive seconds during which the motion lasts.

A body falling freely from rest will, in a given number of seconds, move over a distance which is found by multiplying the square of the number of seconds by 16.1.

§ 3 *Values of g*—The velocity acquired by a body in one second is usually denoted by the symbol g . The following are values of g at different parts of the earth (adapted from Everett *On CGS Units*, p. 12)—

	Latitude	Value of g in Feet per Second	Length in Inch of Pendulum beating Seconds
Equator	0° 0'	32.091	3.9714
Latitude 45°	45 0	32.178	3.9597
Munich	48 9	32.181	3.9607
Paris	48 50	32.183	3.9609
Greenwich	51 29	32.191	3.9610
Copenhagen	51 32	32.191	3.9610
Batavia	59 30	32.194	3.9619
Dubna	58 21	32.196	3.9621
Manchester	53 29	32.196	3.9622
B. West	51 36	32.199	3.9626
Edinburgh	55 37	32.203	3.9632
Abisko	57 9	32.205	3.9632
Pole	90 0	32.255	3.9683

The value of g in feet at a station of which the latitude is λ , and which is h feet above the level of the sea, is in feet

$$g = 32.178 - 0.002 \cos 2\lambda - 0.000003h$$

The length of the pendulum in feet which vibrates in one second is

$$l = 8.2597 - 0.0008 \cos 2\lambda - 0.000003h$$

g is really the excess of gravitation over the centrifugal force arising from the earth's rotation. The value of *gravitation alone* is given by the following expression—

$$g = 295 - 0.026 \cos 2\lambda$$

§ 4 *Algebraic Formulae*—The employment of the symbols and operations of algebra will enable us to express very concisely the results at which we have arrived.

If t denote the velocity acquired in t seconds by a body which has been dropped from a state of rest. Let s denote the number of feet over which the body has moved. The laws we have arrived at may be thus expressed—

$$v = gt, \quad s = \frac{1}{2}gt^2$$

From these equations we can eliminate t and obtain

$$v^2 = 2gs$$

This expresses the velocity acquired in terms of the distance through which the force has acted.

We have hitherto considered the movement of a falling body as being simply dropped. It remains to determine the effect on the movement of the body which would be produced by a certain initial velocity. Let us for simplicity take the case of a body thrown vertically downwards, and calculate the distance through which the body will move in a certain time, as well as the velocity which it will acquire. In the act of throwing the hand moves with a certain velocity, and the body when released starts off with that velocity. It will thus be observed that the act of throwing is merely to impart initial velocity to the body. Let v' be the initial velocity with which the body leaves the hand. Then the velocity of the body at the moment of starting is precisely the same as it would have been had it been dropped from rest $v' - g$ seconds previously. The velocity acquired at the end of t seconds is therefore the same as would have been acquired by a body which fell from rest for a period of $(v' - g + t)$ seconds, whence we have

$$v = v' - g + t$$

$$s = v't + \frac{1}{2}gt^2$$

The distance must obviously be equal to the distance between the distance through which the body would drop from rest in $(v' - g + t)$ seconds and the distance through which a body would drop from rest in $v' - g$ seconds, whence

$$s = \frac{1}{2}g(v' - g + t)^2 - \frac{1}{2}g(v' - g)^2 \\ = \frac{1}{2}g(v'^2 - g^2 + 2v't - g^2 + t^2) - \frac{1}{2}g(v'^2 - g^2) \\ = v't + \frac{1}{2}gt^2$$

The case of a body projected vertically upwards seems at first to present somewhat greater difficulties, but it is really only the same. Such problems can always be readily solved by the help of the following general principle—

A body moving vertically for t seconds will, at the end of that time, be $2gt$ feet nearer the earth than if it would have been had gravity not acted.

If the body be projected vertically upwards with an initial velocity v' , then, if the influence of gravity was suspended, the body would in t seconds ascend to a height $v't$ in the direction of the first law of motion. The effect of gravity will be to reduce the height actually obtained by the amount gt^2 . Whence we have

$$s = v't - \frac{1}{2}gt^2$$

This expression may be written in the form

$$s = v't - \frac{1}{2}gt^2 = \frac{1}{2}g(v' - gt)^2$$

It is therefore obvious that the greatest altitude h is attained when

$$t = v'/g,$$

in which case

$$h = \frac{v'^2}{2g}, \quad v' = \sqrt{2gh}$$

or

As an illustration we may take the case of a body thrown vertically upwards with an initial velocity of 40 feet per second, and in quito where that body will be at the end of two seconds. Had gravity not acted, the body would, in two seconds, have ascended to a height $2 \times 40 = 80$. The action of gravity will reduce this by $2gt = 2g$ feet, and hence the actual height of the body will be $80 - 2g$ feet, = 15.6 if g be taken at 32.2.

§ 5 *Motion of a Projectile*—We have hitherto referred only to the motion of a falling body in a vertical line, in the descent as well as in the ascent. It is now necessary to consider the motion of a body in a straight line at all, but in a curved path due to the motion of the vessel compounded with the actual falling motion. We therefore first consider the effect of the motion of the vessel on the motion of a projectile. Let us suppose that the vessel is moving with a certain initial horizontal velocity, but that notwithstanding that initial velocity the ball still reaches the deck in one second. We are therefore led to the general conclusion that

A body projected horizontally will, at the end of t seconds, have fallen the same space of 16.1 t^2 feet.

An experiment illustrating this result may be made in an evoked and simple manner. Take a marble in the hand, and throw one of the marbles horizontally at the same time as you drop the other.

from the same height, you will find that the two weights reach the ground together. Suppose for simplicity that the height at the moment at which the bodies are released is 1 foot, then the time taken by one of the bodies in falling is half a second. But is both masses reach the ground together, the experiment is really proved to us that a body at the height of 4 feet from the ground will fall 4 feet *later* than the body which is falling from 1 foot. This is exactly true, whatever be the magnitude of the velocity, i.e., whether it is 5, 10, or any other number of feet per second.

We have now studied the effect of gravity upon a body which has been projected either in a vertical line or in a horizontal line. We have found that in each case the effect of gravity is to bring the body 50 ft. later than the surface of the earth in 1 second than it would have been had gravity not acted. We therefore attempted to inquire whether the same statement would not be true for a body projected in any direction. In every way in which this suggestion can be tested it has been found to be verified, and there cannot therefore be the slightest doubt that it is true.

To illustrate this principle we may apply it to the case of a body projected in any direction, and deduce the form of the path in which the body moves. Let O (fig. 2) be the point from which the body is projected, and let OP be the direction in which the body would move after projection if it were not for gravitation. In consequence of the first law of motion, we should find that if it had not been for the action of gravity the ball would reach P₁ in one second, P₂ in two seconds, &c., where OP = P₁P₂ = P₂P₃. Gravitation will, however, make the body swerve from the direction OP, P₁, &c., so that at the end of one second the body is really found at the point A₁, at the end of two seconds at A₂, at the end of three seconds at A₃, &c. The curve drawn through the points A₁, A₂, A₃, &c., which is actually described by the body, can be easily constructed. Take, for example, $t = 8$. If gravity had not been acting, the body would in three seconds have reached the point P₃. We can find where the body actually is by taking a point A₃ which is vertically beneath P₃ at the distance 16×8^2 feet. Similarly we can find where the body is after any other specified number of seconds, and thus we obtain the points A₁, A₂, &c.

The equation of the curve is thus found. Take the line OP as the axis of x , and let α denote the number of seconds during which the motion has lasted, then, if y denote the vertical distance through which the body has been deflected by gravity, we must have $y = \frac{1}{2}gt^2 = 5\alpha^2$.

This curve, being of the second degree, represents a conic section, and as the highest terms form a perfect square, the conic section must be a parabola.

II THE CENTRE OF GRAVITY

§ 6 *Centre of Gravity of a Plate*.—In studying the effect of gravity upon a body which is at rest, it will be convenient to commence with a simple illustrative experiment which can be easily tried. Out of a piece of cardboard of the plate a figure of any shape, ABCDE (fig. 3), is to be cut. A few holes, A, B, C, D, E, are to be punched quite at random in this plate. The plate is to be suspended by passing the nail through any of the holes A, B, C, and D. From the nail it is suspended in the position in which it is at rest, and then released, it will, after a few oscillations, settle down again in the position which it occupied at the first. In order to mark this position, it is desirable to draw on the plate a vertical line in the direction AP, indicated by the plummet line which is hanging in front. If the plate be blackened, this can be neatly done by chalking the plummet line and then giving it a flip against the plate.

When the line has been drawn the plate may be removed from the nail, and again suspended by one of the other holes in its margin, for example B. The plate again assumes a definite position, and again the line and plummet is to be hung on, and a second line drawn as before. The two lines drawn on the plate intersect at a point F. When

Fig 3

the plate is hung from a third hole, C, and a third plummet line is drawn, a third vertical line will be obtained. It is found that the line drawn on the third occasion passes through the intersection of the two former lines—that is to say, all the three lines pass through the same point F. By repeating the operation with other holes, D, E, &c., it is found that all the lines drawn in the way we have described pass through the same point of passing through one definite point of the plate. It is therefore manifest that the point F possesses a very special property, for at it the weight of the body is concentrated the point of suspension when the plate is hanging at rest.

If a hole be actually punched at the position of the point F, and the plate be suspended by passing this hole over the nail, we then find that the plate will remain at rest in any position whatever. This peculiarity of the point F will be more readily perceived if we make a hole in the plate at a point Q near to F. When the plate is suspended from Q it will only be at rest in one position, i.e., when F is vertically beneath Q.

It must surely be regarded as a rather worthy of careful notice that any plate of any figure, regular or irregular, should contain one special point which enjoys the unique property which the experiments show to be possessed by the point F. This point is indicated by a name, it is called the *centre of gravity*.

§ 7 *Centre of Gravity of a Rigid Body*.—In the illustration we have just given, we have spoken merely of a thin plate, because the experiments were more easily conducted in a body of this nature than in one of entirely irregular form. It must not, however, be supposed that a thin plate of uniform thickness is the only kind of body which possesses a point having the properties we have described. No matter what be the shape or materials of which a rigid body is composed, it possesses a centre of gravity. Let ABCD (fig. 4) be a body of any kind, and let it be suspended by a cord from a point A. Then when the body is at rest it assumes a certain position.

We may suppose that a vertical hole A₁ is drilled through the body in the direction of the cord by which the body is suspended. If we now suspend the body by another point on its surface, C₁, the body will come to rest in the position which is represented in fig. 5. It will be found that these two straight holes intersect in the interior of the body at G. In fact, if we thrust a knitting needle through one of the holes, and then attempt to thrust a second knitting needle through the other hole, we shall find that the way is stopped in the interior of the body by the first knitting needle. If the body be now suspended from any other point on its surface, and if a similar hole be made through the point and in the direction of the string by which the body is suspended, it will be found that this hole also passes through the intersection of the two former holes. From each and every point of suspension the same result is obtained, and this we may take to be a definition that in a rigid body of any shape or materials whatever there is one point which possesses the remarkable property thus stated—

When a body suspended by a cord on a point passes to rest, there is one special point which is always vertically beneath the point of suspension, whatever may be the point of the body to which the cord is attached. This point is called the centre of gravity.

In the case of a homogeneous body of regular shape, the centre of gravity is determined from the most simple considerations of symmetry. In the case of a sphere it is obvious that the centre of gravity must be at the centre, for there is no other point of symmetry. In the case of a cube, the centre of gravity must be at the centre of gravity is also situated at the centre of volume. This is found by joining the opposite corners of the figure, and thus making a diagonal, joining another pair of opposite corners we have a second diagonal, and the intersection of these two lines gives the centre of gravity of the mass.

§ 8 *Gravitation of a Rigid Body reduced to One Force*.—A body of any description may be considered to be composed of an unnumbered multitude of small particles of matter. Each of these particles is acted upon by the attraction of the earth. Each particle is therefore urged towards the earth by a certain force which tends towards the earth's centre. The centre of the earth being nearly 4000 miles distant, the directions of these forces may for all practical purposes be regarded as parallel. Even if two particles were a mile distant, the inclination of the directions of the two forces is under a minute. We may therefore treat the forces as parallel without making any appreciable error. The forces may be then compounded into a single force which is parallel to the two components. The forces acting on the two particles of the body may therefore be replaced by a single force. This force may be similarly compounded with the force on a third particle of the body, this resultant with the force on a fourth particle, and so on until all the particles

Fig 4

Fig 5

have been included. We thus come to the important conclusion that the effect of gravity upon a body of any shape is to produce *one force* which acts vertically downwards. It remains to be shown that the *direction of this force passes through the centre of gravity of the body*. Suppose a body of any shape, by a level, then when the body is at rest, the centre of gravity must be vertically beneath the point of suspension. If the direction of this one force which constitutes the effect of gravity does not pass through the centre of gravity, it is its line of action is not vertical, with the direction of the cord of suspension, but it is impossible that two forces should equilibrate unless their lines of action are coincident, where we are led to the important conclusion that the effect of the whole is the line of the cord upon a rigid body is to act vertically downwards, which passes through the centre of gravity of the body and acts vertically downwards.

III UNIVERSAL GRAVITATION

§ 8 *Law of Gravitation between Two Masses*—Investigations of the motions of the planets have furnished us to the conclusion that each planet is attracted towards the sun by a force which varies according to the inverse square of the distance. We have seen also that each of the satellites appears to be attracted towards its corresponding primary planet by a force which obeys the same law. We see therefore that it is right to conclude that the force acts into the proportion that *any two masses in the universe attract each other by a force which varies according to the inverse square of the distance*. (Observations of the most widely distributed stars have been made to show us that this law is in fact obeyed.)

It is called the *law of Gravitation*. It is so called by Sir Isaac Newton, to time.

We suppose that the distance between the two bodies is so great that they can be considered as points.

Let m , m' be the masses of the two bodies, and let r be the distance. The force with which m attracts m' is equal in magnitude through opposite in direction to the force with which m' attracts m . The result is, my perhaps felt some difficulty at first in admitting the truth of this statement. We speak of the effects which the attraction of the sun produces on the planets that it may seem strange to hear that a planet attracts the sun with a force nearly equal and opposite to the force with which the sun acts upon the planets. We can, however, by the aid of a simple illustration, show that such is really the case. Suppose the sun and the earth to be placed at rest, and unobscured by the influence of other mutual gravitation. It is evident that the two bodies would begin moving towards each other, and would after a certain time come into collision. If, however, the earth and the sun had been separated by a rigid rod, it would then be impossible for the two bodies to move closer to each other, so we must consider what the other motion would be produced by their mutual attraction. As the two bodies were mutually at rest, it is clear that there will be no tendency of the rod to move out of the line in which it was originally placed, and consequently if the rod began to move at all it must move in that line, and away with it the earth to one end, and the sun to the other. In this case, the earth and the sun would remain separated at a constant distance, the static energy due to their separation would remain constant, and therefore if they began to move we should have the kinetic energy of their motion directed out of no thing, which is now well known to be impossible. It therefore follows that, under the circumstances we have assumed, the rod would remain at rest at rest. But what are the forces which act upon the rod? At one end of the rod the earth presses upon it with a force which is equal to the attraction of the sun upon the earth. At the other end the sun presses upon the rod with a force which is equal to the attraction of the earth upon the sun. But since the rod remains at rest, these two forces must be equal and opposite, and hence the force with which the sun attracts the rod must be equal and opposite to the force with which the earth acts the sun.

If we express the gravitation of two masses in the form

$$f(m, m') = \frac{1}{r^2},$$

then m and m' must enter symmetrically into the expression, for if the two masses were interchanged the gravitation must not be altered.

We should here also advert to a circumstance connected with gravitation which is of the very highest importance. Suppose we take two definite masses (for simplicity, two pounds) separated at a definite distance (for simplicity, one foot), then the gravitation of these two masses to each other is a *certain definite force* (which we shall subsequently calculate). What we want here to say is that the stress upon is that, so far as we know at present, this force appears to be the same whether the material of which the two masses are composed. Thus two pounds of iron at a distance of one foot attract each other with the same force as two pounds of wood attract a pound of lead at the same distance. The significance, or perhaps it should be said the very importance, of this statement is apt to be lost sight of from the somewhat peculiar circumstance that, when it is used that two masses are equal to each other, what is really meant is that, if equal

forces were to act upon each of the masses for the same time, the masses would receive the same velocity. As this test of the equality of masses is not justly convenient, the weighing scales have come into use for the purpose, and though it appears to be true that when two masses have equal "weights," equal "weights" by the scales, then the masses are themselves equal, yet this is so far from being an obvious or necessary truth that it is only in the most remarkable phenomenon connected with gravitation. The explanation for the violation of two attracting masses must therefore depend solely upon their mass, upon their distance, and upon some specific constant which is characteristic of the intensity of gravitation.

Experiment shows that the gravitation of a body towards the earth is directly proportional to its mass, and hence we see that the expression

$$f(m, m') = \frac{1}{r^2}$$

must be proportional to m , and so $f(m, m')$ must be unaltered by the interchange of m and m' , it appears finally that the gravitation of the two masses is

$$em'm' = \frac{1}{r^2},$$

where e is a numerical constant which is equal to the gravitation of two units of mass placed at the unit of distance. To form a definite conception of the intensity of this force, we take some specific instance. It can be shown that two masses A and B , each containing 116,000 tons of matter, and situated at a distance of one statute mile apart, will not exert on each other more than one quarter of a pound. If A and B remain the same, and if the distance between them be increased to two miles, then the intensity of the force with which the masses gravitate together is reduced to one quarter of a pound. If the distance of the masses be doubled, the distance being unaltered, then the force would be doubled. If both the masses be doubled, then the force would be quadrupled.

§ 10 *Motion of a Planet round the Sun*—The effects of gravitation upon the bodies as in actual motion must next receive our attention. It may so happen that in consequence of the attraction of gravitation one of the bodies will actually describe a circle around the other, so that, notwithstanding the effect of the attraction, the distance between the two bodies remains constant. We shall first explain, by elementary considerations, how it is possible for a planet to continue to revolve in a circle, or nearly circular orbit about the sun in its centre, and then we shall proceed to the more exact consideration of the form of the orbit, and the laws according to which that orbit is described.

Let S represent the sun (fig. 8), and let T be the initial position of the planet. If the planet is simply released, it will immediately begin to fall along the line TS into the sun. If, on the other hand, the planet were initially projected along the line TZ perpendicular to TS , the attraction of the sun at S will deflect the planet from the line TZ which it would otherwise have followed, and compel the planet to move in a curved line. The path taken in a curved line which the planet will describe depends upon the initial velocity. With a small initial velocity the deflecting power of the sun will have a more speedy effect than is possible, when the initial velocity is considerable.

The rapidly curving path TX will therefore correspond to a small initial velocity, while the flatter curve TY may be the orbit when the initial velocity is considerable. As the more momentum proceeds, the velocity of the planet will generally increase. If the planet were more energy along the moving along the curve TX after leaving T going farther away from the sun. It is manifest that the planet is thus going against the sun's attraction, and therefore its velocity must be diminishing. On the other hand, when the planet is moving along the curve TY , it is constantly getting nearer the sun, and the effect of the sun's attraction is to increase the velocity. It is therefore plain that for a path somewhere between TX and TY the velocity of the planet must be unaltered by the sun's attraction. With centre S and radius TS draw a circle and mark a point P on that circle exceedingly near to T . With a certain initial velocity it is possible to project the planet so that it shall describe the arc TP . The attraction of the sun always acts along the radius and hence in describing the arc TP the planet has at every instant been moving perpendicularly to the sun's attraction. It is manifest that under such circumstances the sun's attraction cannot have altered the velocity, for it would be impossible to give a reason for the velocity having less or more than it originally had, but it is evident that the velocity having been retained. We thus see that the planet revolves P with an unaltered velocity at that point of the orbit. If the direction of the motion is perpendicular to the radius, it is therefore plain that the velocity of the planet will again describe a small portion of the circle, which it will be followed by another, and so on, i.e., the planet will continue to move in a circular orbit. We have therefore shown that, if a planet were originally projected with a certain specific velocity

Fig. 8

With these substitutions, we have for the values of T , V , W , the following expressions

$$T = -\frac{emv(M+m)}{r^2} + emv\left(\frac{1}{r^2} - \frac{1}{r^2}\right)' \cos \psi \cos (\ell' - \ell) - \frac{emv^2}{r^2}$$

$$V = -emv\left(\frac{1}{r^2} - \frac{1}{r^2}\right)' \cos \psi \sin (\ell' - \ell)$$

$$W = emv\left(\frac{1}{r^2} - \frac{1}{r^2}\right)' \sin \psi$$

It will be noticed that the first term of the expression for T consists of the force which corresponds to the purely elliptic motion. The two remaining terms in T , as well as the whole of V and W , depend upon the disturbing force, as is evident from the circumstances that they contain m' as a factor, and would vanish if m' were equal to zero. As b' is small, we may neglect its squares and higher powers, so that

$$\cos b' = 1 \text{ and } \sin b' = b'$$

When these substitutions are made, we see that the expressions for T and V are both independent of b , and consequently we may, so far as these forces are concerned, consider the motions of the disturbing and the disturbed body to take place in the same plane. The expression for W contains, however, the first power of the latitude of the disturbing body. This is of course connected with the circumstance that it is, only in consequence of the disturbing force W that the disturbed body is induced to leave the plane of its undisturbed motion at all.

§ 14 *Calculation of Disturbed Motion*—Observation has shown that, notwithstanding the perturbations, the orbit of each planet differs but little from a circle, of which the sun is the centre. It is further shown by observation that, though the rate at which a planet moves in its orbit is not quite constant, it is still very nearly so. We may make a similar statement with reference to the motion of the moon around the earth. The orbit of the moon is nearly a circle, of which the earth is the centre, and the velocity of the moon in its orbit is nearly constant. These features of the motions of the planets and the moon enable us to replace the more exact formulae by approximate expressions which are much more convenient, while still sufficiently correct.

Let ρ , θ be the polar co-ordinates of a celestial body which moves nearly uniformly in a nearly circular orbit. The form of the orbit may be expressed by an equation of the type

$$\rho = f_1(\theta), \quad \theta = f_2(\rho)$$

It will, however, be more convenient to employ two equations, by means of which the coordinates are each expressed directly in terms of the time. We thus write two equations of the form

$$\rho = f_1(t), \quad \theta = f_2(t),$$

and by elimination of t from these equations the ordinary equation in polar coordinates is obtained. With reference to the forms of the functions f_1 and f_2 , we shall make an assumption.

Let χ_1 , χ_2 , &c., be arbitrary angles, ω_1 , ω_2 , &c., arbitrary angular velocities, a_1 , a_2 , &c., small arbitrary linear magnitudes, and η_1 , η_2 , &c., small numbers less than unity, and ω an arbitrary linear magnitude, and ω is an arbitrary angular velocity. We shall assume that

$$\rho = a + a_1 \cos (\omega t + \chi_1) + a_2 \cos (\omega t + \chi_2) + \dots$$

$$\theta = \omega t + \eta_1 \sin (\omega t + \chi_1) + \eta_2 \sin (\omega t + \chi_2) + \dots$$

To justify our employment of these equations it would ideally be sufficient for us to state that, as a matter of fact, the motions of all the heavenly bodies which are at present under consideration are capable of being expressed in the form we have written. It may, however, facilitate the reader in admitting the legitimacy of this assumption, if we point out how exceedingly plausible are the *a priori* arguments which can be adduced. Thus ρ is what is called a *periodic function of the time*. It is necessary that the mode in which the time t enters into the expression for ρ must fulfil the condition of containing t within narrow limits, notwithstanding the indefinitely great number of values t is susceptible of. It is obvious that this condition is fulfilled in the form we have assumed for ρ . Under all circumstances

$$\rho = > \omega t + \eta_1 \sin \chi_1 + \eta_2 \sin \chi_2, \text{ &c.},$$

$$\rho = < \omega t + \eta_1 \sin \chi_1 + \eta_2 \sin \chi_2, \text{ &c.},$$

and as a_1 , a_2 , &c., are small quantities it appears that ρ is necessarily restricted to narrow limits.

By similar reasoning we can justify the equation for θ , for we can show that the angular velocity of the celestial body to which it refers must be approximately uniform.

By differentiation,

$$\frac{d\rho}{dt} = \omega + \eta_1 \omega_1 \cos (\omega t + \chi_1) + \eta_2 \omega_2 \cos (\omega t + \chi_2) + \dots$$

Under all circumstances we must have

$$\frac{d\rho}{dt} > \omega - \eta_1 \omega_1 - \eta_2 \omega_2 - \dots, \text{ &c.},$$

$$\frac{d\rho}{dt} < \omega + \eta_1 \omega_1 + \eta_2 \omega_2 + \dots, \text{ &c.},$$

and as η_1 , η_2 , &c., are all small quantities, it is obvious that $\frac{d\rho}{dt}$ is confined within narrow limits, notwithstanding the indefinite magnification of the time.

In addition to the reasons already adduced in justification of the expressions of ρ and θ , it is to be remarked that the number of the possible constants, a_1 , a_2 , &c., χ_1 , χ_2 , &c., η_1 , η_2 , &c., ω_1 , ω_2 , &c., ω , is practically indefinite, and that consequently the equations can be compelled to exhibit faithfully the probabilities of any approximately circular orbit described by a particle moving with approximate uniformity.

§ 15 *Determination of the Forces*—The orbit which is described by a planet or other celestial body being given by the equations

$$\rho = a + \sum \eta_i \cos (\omega t + \chi_i),$$

$$\theta = \omega t + \sum \eta_i \sin (\omega t + \chi_i),$$

it is a determinate problem to ascertain the forces by which the motion of the planet is controlled. In making this calculation we shall assume that the squares and higher powers, and also the products of the small quantities a_1 , a_2 , &c., η_1 , η_2 , &c., may be neglected. It is to be computed from the well known formula

$$T = m \left(\frac{d^2 \rho}{dt^2} - \rho \frac{d^2 \theta^2}{dt^2} \right),$$

where we have

$$\frac{d\rho}{dt} = -\sum a_i \omega_i \sin (\omega t + \chi_i),$$

$$\frac{d^2 \rho}{dt^2} = -\sum a_i \omega_i^2 \cos (\omega t + \chi_i),$$

$$\frac{d\theta}{dt} = \omega + \sum \eta_i \omega_i \cos (\omega t + \chi_i),$$

$$\frac{d^2 \theta}{dt^2} = \omega^2 + 2 \sum \eta_i \omega_i \omega \cos (\omega t + \chi_i),$$

$$\frac{d^2 \rho}{dt^2} - \rho \frac{d^2 \theta^2}{dt^2} = -\omega^2 + \sum (2 \eta_i a_i \omega_i + a_i \omega^2) \cos (\omega t + \chi_i),$$

whence by substitution

$$T = -m \omega^2 - \sum (2 \eta_i a_i \omega_i + a_i \omega^2) \cos (\omega t + \chi_i)$$

To compute V , the force perpendicular to the radius vector, we proceed as follows—

$$\frac{d^2 \rho}{dt^2} = -\omega^2 + 2 \sum \eta_i a_i \omega_i \cos (\omega t + \chi_i),$$

$$\frac{d\theta}{dt} = \omega + \sum \eta_i \omega_i \cos (\omega t + \chi_i),$$

whence we find

$$\rho \frac{d^2 \theta}{dt^2} = \omega^2 \rho + \sum (2 \eta_i a_i \omega_i + \eta_i \omega_i^2) \cos (\omega t + \chi_i)$$

Differentiating we have

$$\frac{d}{dt} \left(\rho \frac{d^2 \theta}{dt^2} \right) = -\sum (2 \eta_i a_i \omega_i + \eta_i \omega_i^2) \sin (\omega t + \chi_i)$$

Substituting this in the ordinary formula

$$V = \frac{m}{\rho} \frac{d}{dt} \left(\rho \frac{d^2 \theta}{dt^2} \right)$$

we have finally

$$V = -\sum (2 \eta_i a_i \omega_i + \eta_i \omega_i^2) \sin (\omega t + \chi_i)$$

Let us assume, for the sake of brevity,

$$\lambda_1 = \omega t + \chi_1, \quad \lambda_2 = \omega t + \chi_2, \text{ &c.}$$

$$\frac{a_1^2}{\omega_1^2} = a_1^2 (\omega^2 + \omega_1^2) + 2 \eta_1 a_1 \omega \omega_1, \quad \frac{a_2^2}{\omega_2^2} = a_2^2 (\omega^2 + \omega_2^2) + 2 \eta_2 a_2 \omega \omega_2,$$

$$\frac{a_1^2}{\omega_1^2} = a_1^2 (\omega^2 + \omega_1^2) + 2 \eta_1 a_1 \omega \omega_1, \quad \frac{a_2^2}{\omega_2^2} = a_2^2 (\omega^2 + \omega_2^2) + 2 \eta_2 a_2 \omega \omega_2,$$

then the result to which we have been conducted may be thus stated—
If a body be moving in a nearly circular orbit under the influence of a radial force equal to

$$-m \omega^2 - m \omega^2 \cos \lambda_1$$

and a force perpendicular to the radius vector equal to

$$-m \omega a_1 \sin \lambda_1$$

then the path which the body describes is defined by the equations

$$\rho = a + \sum \eta_i \cos \lambda_i,$$

$$\theta = \omega t + \sum \eta_i \sin \lambda_i,$$

§ 16 *Deductions from these Equations*—We proceed to point out a few of the more remarkable deductions from this theorem.

If as a first approximation we neglect entirely the small quantities a_1 , a_2 , &c., η_1 , η_2 , &c., we have

$$\rho = a, \quad \theta = \omega t$$

In this case the orbit described by the body is a circle of which the radius is a . The angle made by the radius vector to the particle with a fixed axis is proportional to the time. It follows that the velocity with which the particle moves in the orbit is un-

from ω . Since the angle swept out by the particle in one unit of time is equal to ω , it follows that the angular velocity of the particle is equal to ω , since the radius is a , the actual velocity with which the particle is moving in its orbit is $a\omega$. In the case now under consideration the force P is perpendicular to the radius vector is constant, equal to $2\pi a\omega$. If we take the initial time which it is upon the particle is ω divided along the radius vector, and is equal to $-\sin\omega$. The $\sin\omega$ merely expresses that the force, which acts upon the particle, makes it constantly describe ω around the centre. To find the orbit the particle time of the motion of the particle in its orbit. Then we must find the angular velocity by dividing the angle 2π described in the time p by the time p , whence

$$\frac{2\pi}{p} = \omega$$

By substituting this value for ω in the expression for T , we deduce

$$T = a\omega \frac{1}{\sin\omega}$$

This proves that the force must vary directly as the value of the orbit of the particle and inversely as the square of the periodic time in which the orbit is described.

Let us now consider the case in which σ_1 and σ_2 are retained, while the remaining quantities $\sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7, \sigma_8, \sigma_9, \sigma_{10}$ are all equal to zero. The formulae then are

$$\begin{aligned} r &= a(1 + \sigma_1 \cos \theta), & T &= 2\pi a\omega - a\sigma_1 \omega^2 \cos \lambda_1 \\ \theta &= \omega t + \sigma_1 \sin \theta, & V &= a\omega \sin \lambda_1 \\ \text{whence } \sigma_1 &= a_1(a + a_1) + 2\sigma_1 a\omega \cos \lambda_1, & \sigma_1 &= 2\sigma_1 a\omega \cos \lambda_1 + a_1 a_1 \end{aligned}$$

It is clear in the last place that the orbit is not a circle, for as λ_1 depends upon t , it will follow that this λ_1 in a way between the limits $+\lambda_1$ and $-\lambda_1$, so that the radius vector r may also vary between the extreme values $a + \sigma_1$ and $a - \sigma_1$. As σ_1 is extremely small, it appears that the orbit is still nearly circular with a radius a , but that the particle may sometimes be found at a distance σ_1 on the inside or outside of the circle.

We shall similarly find that the angular velocity with which the radius vector sweeps round is not quite uniform. The average angular velocity is ω , but the actual position of the radius vector differs by the quantity $\sigma_1 \sin \lambda_1$ from what it would have been had its motion been uniform. As $\sigma_1 \sin \lambda_1$ must vary between the limits $+\sigma_1$ and $-\sigma_1$, it follows that the radius vector can never be at an angle θ from ωt in any plane, i.e., the place which it would have occupied had it continued to move uniformly. The orbit is completely defined by the two equations—

$$\begin{aligned} \theta &= \omega t + \sigma_1 \sin(\omega t + \lambda_1), \\ r &= a + \sigma_1 \cos(\omega t + \lambda_1) \end{aligned}$$

If from these two equations the time t could be eliminated, the result would be the equation in polar coordinates of the path which the particle described. Owing, however, to the fact that the quantity t occurs separately, and also under the form of a sine and cosine, this elimination would be transcendental.

If, however, we take advantage of the smallness of σ_1 and σ_2 , we can eliminate t with sufficient accuracy for all practical purposes. It is θ is small equal to ωt , we may assume for t in the last part of the approximation the value $\theta = \omega t$. If we consider the squares or higher powers of σ_1 and σ_2 negligible, the value of θ may be substituted for t under the sine and cosine, and we have

$$r = a + \sigma_1 \cos(\omega t + \lambda_1)$$

This equation in general denotes a curve undulating about the circumference of the circle of which the radius is a .

We must now briefly consider the case where the motion of the particle is not confined to a plane. Suppose a third axis OC be drawn through the point O perpendicular to the plane which contains the undisturbed orbit. Let ϕ be the coordinate of the particle parallel to the line OC which is called the axis of z , while x, y denote the coordinates referred to the other two principal axes. We shall suppose that the motion of the particle is such that the coordinate z can be expressed by the equation

$$z = h_1 \sin \beta_1 + h_2 \sin \beta_2 + \dots$$

where h_1, h_2, \dots , are all of constant length, β_1, β_2, \dots , are angles of the form $p_1 t + q_1$, $p_2 t + q_2$, $p_3 t + q_3$, $p_4 t + q_4$, $p_5 t + q_5$, $p_6 t + q_6$, $p_7 t + q_7$, $p_8 t + q_8$, $p_9 t + q_9$, $p_{10} t + q_{10}$, are constants, and t denotes the time.

Let W denote the force which acts upon the particle P in a direction parallel to the axis of z . Then we have

$$W = m \frac{d^2 z}{dt^2}$$

Differentiating the equation

$$z = h_1 \sin \beta_1 + h_2 \sin \beta_2 + \dots$$

we have

$$\frac{dz}{dt} = h_1 \cos \beta_1 \frac{d\beta_1}{dt} + h_2 \cos \beta_2 \frac{d\beta_2}{dt} + \dots$$

but

$$\frac{d\beta_1}{dt} = p_1, \quad \frac{d\beta_2}{dt} = p_2, \dots$$

whence

$$\frac{dz}{dt} = p_1 h_1 \cos \beta_1 + p_2 h_2 \cos \beta_2 + \dots$$

Differ.iating again

$$\frac{d^2 z}{dt^2} = -p_1^2 h_1 \sin \beta_1 - p_2^2 h_2 \sin \beta_2 - \dots$$

whence, finally,

$$W = -mp_1^2 h_1 \sin \beta_1 - mp_2^2 h_2 \sin \beta_2 - \dots$$

§ 17 *The Motion of the Moon*.—One of the most important problems to which we may apply the expressions to which we have been indebted is to an examination of the disturbances which the moon experiences in its motion round the earth. The moon would describe a purely elliptic motion round the earth in the case of the earth if not for the presence of the sun disturbing the motion and producing an irregular orbit. Notwithstanding the vast mass of the sun, these disturbing causes still only slightly derange the moon's motion from what it would be were these disturbing causes absent. The reason of this is that the sun is about 400 times as far from the earth as the moon, and consequently the difference of the effects of the sun upon the earth and the moon is comparatively small.

In applying the formulae to the case of the moon we denote by S, E, P the earth, the moon, and the sun respectively, M, m, m' signify the masses of the earth, moon, and sun, r, r', r'' are the distances of the moon and the sun from the earth, $\lambda, \lambda', \lambda''$ are the longitudes of the moon and the sun measured in the moon's orbit.

T, V, W are the forces acting upon the moon, where T is along the radius vector, V is perpendicular to the radius vector, and W is perpendicular to the plane of the moon's orbit.

Since r, r' is very nearly equal to $1-400$, we may regard this fraction as that in which the sun is equal and higher powers are negligible. Hence, since $\cos \lambda = 1$,

$$\begin{aligned} r &= r' \left(1 - \frac{2}{400} \cos(\lambda - \lambda') + \frac{1}{400^2} \right)^{\frac{1}{2}} \\ &= r' \left(1 - \frac{1}{200} \cos(\lambda - \lambda') \right), \end{aligned}$$

whence

$$r^3 = r'^3 \left(1 + \frac{3}{200} \cos(\lambda - \lambda') \right),$$

or

$$\frac{1}{r^3} = \frac{1}{r'^3} \left(1 - \frac{3}{200} \cos(\lambda - \lambda') \right).$$

With these substitutions we have, after a few simple transformations,

$$T = -\frac{GM(M+m)}{r^2} + \frac{GMm'}{r'^2} \left(1 + 3 \cos 2(\lambda - \lambda') \right),$$

$$V = -\frac{3}{2} \frac{GMm'}{r'^2} \sin 2(\lambda - \lambda'),$$

$$W = \frac{3}{4} \frac{GMm'}{r'^2} \cos 2(\lambda - \lambda') \sin V$$

§ 18 *The Perturbation*.—The inequality in the motion of the moon which is known as the variation is independent both of the eccentricity of the orbit of the moon and of that of the earth. As we shall at present only discuss inequalities in longitude and radius vector, and as we shall neglect small quantities of an order higher than the second, we may assume that the plane of the orbit of the sun coincides with the plane of the orbit of the moon.

The radius vector and the longitude may be expressed by the formulae

$$\begin{aligned} r &= a + \sigma_1 \cos \lambda_1, \\ \lambda &= \omega t + \lambda_1 \sin \lambda_1 \end{aligned}$$

We shall assume that

$$2(\lambda - \lambda_1) = \lambda_2$$

and since

$$r^3 = a^3 \left(1 - \frac{3}{200} \cos \lambda_2 \right),$$

we have

$$\begin{aligned} T &= -\frac{GM(M+m)}{r^2} + \frac{1}{2} \frac{GMm'}{r'^2} \\ &\quad + \left(\frac{3}{2} \frac{GMm'}{r'^2} \frac{m}{a^3} + \frac{3}{2} \frac{GMm'}{r'^2} \right) \cos \lambda_2, \end{aligned}$$

but from § 15, in being the mean motion of the moon,

$$T = m\omega^2 a - m\omega^2 \lambda_1$$

whence, by identifying the two expressions we have from the previous independent of the time,

$$m\omega^2 a = \frac{GM(M+m)}{a^3} - \frac{1}{2} \frac{GMm'}{r'^2}$$

This is a very important formula, inasmuch as it gives the relation between the mean motion ω and the mean distance a in the disturbed orbit.

Suppose that there were no disturbing influence, and that a satellite moved uniformly around the earth in a circular orbit of radius a , with a mean motion ω_0 , then we have

$$GM(M+m) = m\omega_0^2 a^3$$

Assuming also that the earth moves uniformly round the sun in a circular orbit of radius a' with a mean motion ω' , then

$$GM(M+m') = m'\omega'^2 a'^3$$

or, since M is negligible in comparison with m' ,
 $\frac{m'}{m} = \frac{m'}{m} \frac{a'}{a}$

With these substitutions, and making $u = m'^2 - m^2$, we have finally
 $\frac{m'}{m} a' = \frac{m'}{m} a \left(1 - \frac{1}{2} \frac{u}{a^2}\right)$

If we identify the coefficients of $\cos \lambda_1$ in the two expressions for T , we have

$$-maF_1 = 2f_1 \frac{\sin(M + m)}{a^2} + \frac{3}{2} \frac{\sin m}{a^4},$$

whence, by substitution and by neglecting small quantities,

$$f_1(n^2 - n_1^2) + 2f_1 n_1 a_1 = -2f_1 n^3 - \frac{3}{2} \frac{m^3}{a^4}$$

We have also for V the two expressions

$$-\frac{3}{2} \frac{m^3}{a^4} - \sin \lambda_1,$$

and

$$-maG_1 \sin \lambda_1,$$

whence by identifying the coefficients

$$2f_1 n_1 + g_1 n_1^2 = \frac{3}{2} \frac{m^3}{a^4}$$

where n_1 denotes the rate at which λ_1 alters

Solving the two equations, we deduce the following expressions —

$$f_1 = -\frac{3m^3 n_1 + 2n^3}{2(n_1^2 - n^2)}, \quad g_1 = \frac{3m^3(n_1^2 + 2n_1 + 8n^2)}{2(n_1^2 - n^2)},$$

We can now calculate the value of f_1 and g_1 numerically. For

$$\frac{n_1}{n} = \frac{25 - n'}{n} = \frac{865.255 - 37.322}{965.255} = 1.8501,$$

and also

$$\frac{m}{a} = \frac{1}{178.72},$$

from these we deduce

$$f_1 = -0.007204$$

$$g_1 = +0.0241 - 35' 30''$$

The results at which we have arrived may be thus summarily stated, namely, however, a more accurate value of g_1 than that which is formed by this method —

If we suppose the orbit of the moon to coincide with the plane of the ecliptic, and if we neglect the ellipticity of the orbit of the earth around the sun and that of the moon around the earth, if n' denotes the mean motion of the earth around the sun, and n the mean motion of the moon around the earth, and, finally, if a and a' be connected by the equation

$$n'a^3 = 0.9972 (M + m),$$

then we have for the motion of the moon the equations

$$\ddot{r} = a(1 - 0.007204 \cos(2nt - 2n't)),$$

$$l = nt + 39' 30'' \sin(2nt - 2n't)$$

We thus see that the motion of the moon, on the hypothesis which we have assumed, is different from a uniform circular motion. The distance from the moon to the earth is sometimes 1.8501 part greater or less than its mean value. And the longitude of the moon is sometimes $39' 30''$ in advance of or behind what it would be on the supposition that the moon is moving uniformly. When the distance is the greatest, we have $\cos(2nt - 2n't) = -1$, whence

$$2nt - 2n't = \pi \text{ or } \pi \mp \pi,$$

and it follows that at the distance of the moon from the earth is great at its quadratures. When the distance is 1.75, then

$$\cos(2nt - 2n't) = +1,$$

whence

$$2nt - 2n't = 0 \text{ or } 2\pi,$$

consequently the moon is nearest to the earth at $53' 39''$. It thus appears that the orbit of the moon is modified by the disturbing influence of the variation of the earth in orbit of which the earth is the centre, and of which the nearest axis is constantly in the line of $53' 39''$.

The mean longitude of the moon and the true longitude coincide when

$$\sin(2nt - 2n't) = 0$$

This condition is fulfilled both at $53' 39''$ and quadrature, consequently the mean place of the moon and its true place coincide when the moon is either in $53' 39''$ or in quadrature. The true place of the moon is at its greatest distance in advance of the mean place when

$$\sin(2nt - 2n't) = -1$$

This condition is fulfilled at the middle points of the first and third quadrants, while at the middle points of the second and fourth quadrants

$$\sin(2nt - 2n't) = +1,$$

and the moon is behind its mean place in the second and fourth quadrants.

After new moon, the distance between the moon and the earth gradually increases, and the apparent velocity of the moon also increases, until, when the moon is three or four days old, it has advanced $39'$ beyond its mean place, the velocity then begins to diminish, though the distance goes on increasing, until the quadrants the distance has attained a maximum. After first quarter the distance diminishes, and the moon falls behind its mean place, the maximum distance of $39'$ behind the moon place being reached about 11 days after new moon. At full moon the distance has become a minimum, and the moon place and true place coincide. At 15 days, the true place has again gained $39'$ on the mean place, but the distance increases, and at third quarter the distance is again a minimum, and the true and the mean place coincide. After passing third quarter the distance diminishes, and the true place falls behind the mean place, the distance attaining a minimum on the 26th day, after which the true place gains on the mean place, with which it coincides at new moon, when also the distance is again a minimum.

Since the amount of this irregularity in longitude is so considerable, being in fact larger than the diameter of the moon itself, it is very appreciable even in comparatively coarse observations. It was discovered by observation by Tycho Brahe, by whom it was named the variation.

It would be too fat to endeavor to trace out any of the other irregularities by which the motion of the moon is disturbed. We have taken the variation merely as an illustration of one of the numerous corrections which the law of gravitation has explained. The coincidence which subsists between the values of these corrections as computed by theory and as determined by observation affords the most conclusive evidence of the truth of the law of universal gravitation.

(R S B)

GRAVITY, SPECIFIC See HYDRODYNAMICS

GRAY, the chief town of an encirclement in the department of Haute-Saône, is situated on the declivity of a hill on the left bank of the Saône, 37 miles S.W. of Vesoul by rail. Its streets are narrow and steep, but it possesses broad and beautiful quays, and the Allée des Capucins is a fine promenade. The principal buildings are the old castle of the duke of Burgundy, the church in the style of the Renaissance, the communal college (with a library of 16,000 volumes and a natural history museum), the theatre, and the barracks. The town possesses very large flour-mills, and among the other industries are ship-building, dyeing, tanning, haircloth-weaving, plaster-casting, and the manufacture of machinery, oils, and starch. There is also a considerable trade in iron, corn, provisions, vegetables, wine, and wood. The population in 1876 was 7350. Gray was founded in the 7th century. Its former

¹ When the approximation is carried sufficiently far it is found that the coefficient of the variation is $39' 30''$.

defensive works were destroyed by Louis XIV in 1688. During the Franco-Prussian war General von Weider concentrated his army corps in the town, and held it for a month, making it the point d'appui of movements towards Dijon and Langres, as well as towards Besançon.

GRAY, DAVID (1838-1861), Scottish poet, was the son of a hand loom weaver, and was born at Melkild, a small village on the banks of the Luggie, about 8 miles from Glasgow, January 29, 1838. His parents, observing his fondness for study and his exceptional cleverness, resolved to educate him for the church, and through their self-denial and his own exertions as a pupil teacher and private tutor, he was able, after receiving the rudiments of education at the parish school of Kirkmildon, to complete a course of four semesters at the university of Glasgow. It soon, however, became evident that the vision of poetry and world fame had begun to lure him away from the path which his parents' desires had marked out for him. His most intimate companion at this time was Robert Buchanan, the now

well known poet, and in May 1860 the two agreed to proceed to London, with the definite purpose of finding some kind of employment in connection with literature. Shortly after his arrival in London Gray introduced himself to Mr. Monckton Milnes, now Lord Houghton, with whom he had previously corresponded, who, though unsuccessful in his application for a place for Gray's poem, "The Luggie," in the *Contest Magazine*, gave him some light literary work. He also showed him great attention when a cold which had seized him assumed the serious form of consumption, and procured him the means of staying for a time in the south of England, but as the disease made rapid progress, an inviolable longing seized Gray to return to Melksham, where he arrived in January 1861, and died on the 3d December following, having the day before had the gratification of seeing a painted specimen copy of his poem *The Luggie*. He was buried in the Alder Aisle Churchyard, Kirtlington, where in 1863 a monument was erected by "friends far and near" to his memory.

The *Luggie*, the principal poem of Gray, is a kind of review in which the scenes and events of his childhood and his early aspirations are mingled with the music of the stream which he celebrates. The series of sonnets *In the Shadow*, composed during the latter part of his illness, possess, without the smallest taint of morbidness, a touching and solemn beauty in keeping with the circumstances in which they were written. Most of his poems necessarily bear traces of immaturity, and lines may frequently be found in them which are mere echoes from Thomson, Wordsworth, or Tennyson, but they possess, nevertheless, the distinct individuality of true genius. They nearly all have a direct or indirect reference to phases of outward nature, and they give evidence of an undying wealth of imagination and sentiment, of a true and vigorous power of conception, and of a gift of clear and strong, yet subtle and tender, musical utterance, which apparently only required to have been mellowed by time and experience in order to have fashioned a poetry which would have given him an enduring name in English literature.

The Luggie and other Poems, with an introduction by R. Monckton Milnes, and a brief notice by James Holden, was published in 1862, and a new and enlarged edition of Gray's *Prædial Works*, edited by the late Sheriff Glasgow Bell, appeared in 1874. See also the "Poem on David Gray," published originally in *Corwall Magazine*, and reprinted in *David Gray and other Essays*, by Robert Buchanan, 1888, and the poem on David Gray, separated there from *Tidals and Legends of Inverburn*.

GRAY, JOHN EDWARD (1800-1875), a distinguished English naturalist, born at Walsall, Staffordshire, in 1800, was the eldest of the three sons of Mr S. F. Gray, of that town, lawyer and writer on botany, author of the *Supplement to the Phytogeography*, &c., and grandson of Mr S. Gray, who translated for Lee the *Philosophia Botanica* of Linnæus, and assisted in the composition of the *Introduction to Botany*. Gray studied at St. Bartholomew's and other hospitals for the medical profession, but was attracted to the more enlivening pursuit of botany, on which he wrote and lectured. At an early age he assisted his father by collecting notes on botany and comparative anatomy and zoology in Sir Joseph Banks's library at the British Museum, aided by Dr W. E. Leach, assistant-keeper. The systematic synopsis of the *Natural Arrangement of British Plants*, 2 vols., 1821, was prepared by him, his father writing the preface and introduction only. This work, which introduced the natural system of plants on Jussieu's plan to the student of English botany, gave offence to the Linnæan Society, who rejected Gray's application for a fellowship in 1822. Chafed at this unwelcome rebuff, he turned to the study of zoology, writing on zoophytes, shells, *Mollusca*, and *Papilionacea*, still aided by Dr Leach at the British Museum. In December 1824 Gray obtained the post of

assistant in that institution, and from that date to December 1839, when Mr J. G. Children retired from the keepership, he had so zealously applied himself to the study, classification, and improvement of the national collection of zoology that he was selected as the fittest person to be entrusted with its charge. Immediately on his appointment as keeper, Gray took in hand the revision of the systematic arrangement of the collections, scientific catalogues followed in rapid succession, the department was raised in importance, its poverty as well as its wealth became known, and whilst increased grants, donations, and exchanges made good many deficiencies, great numbers of students, foreign as well as English, availed themselves of its resources to enlarge the knowledge of zoology in all its branches. Gray found the representatives of the animal kingdom confusedly huddled together in old Montagu House, and the science of zoology was just then emerging from infancy, with little public support to foster it. But, in spite of numerous obstacles, he worked up the department, within a few years of his appointment as keeper, to such a state of excellence as to make it the rival of the cabinets of Leyden, Paris, and Berlin, and later on it was raised under his management to the dignity of the largest and most complete zoological collection in the world. The extensive acquaintance which he had obtained with practical zoology, his love of the subject, close application, and original views, his skill and accuracy of observation, his readiness to impart the information he had acquired to any one who sought it, and above all his marvellous industry, placed Gray in the foremost rank of naturalists. It has been said that he tried to accomplish too much, that he wrote hurriedly and paid little attention to anatomy, but it must be remembered that he laboured for the past generation, not among the one-subject men of the present age. He did his work nobly, though somewhat roughly, and it will ever be appreciated by generous men of science. His eagerness for controversy, and the outspoken plainness with which he asserted his views, sometimes brought him into unpleasant relations with those he had to do with. Of this the catalogue disputes with Panizza, and the gorilla dispute with Dr. Chailin, Owen, and others, are well known instances. Although seized with paralysis in 1870, Gray continued to discharge the functions of keeper of zoology, and to contribute papers to the *Annals of Natural History*, his favourite journal, and to the transactions of a few of the learned societies. At Christmas 1874, having completed half a century of official work, he resigned office, and on the 7th of March 1875 this indefatigable naturalist expired.

Gray was elected a fellow of the Royal Society in 1832, in 1836 the honorary degree of doctor of philosophy of the university of Munich was conferred upon him, in recognition of his formation of the largest zoological collection in Europe, and in 1880 the king of Wurtemberg, desiring to make the estimation in which he held Gray, who had declined an offer of knighthood, bestowed upon him the gold medal of merit. He was a president of the Entomological Society, vice president of the Zoological and Microscopical Societies, fellow of the Geographical and Palæontological Society, in the formation of which he took part, he was president of the Botanical Society, and also a fellow of the Linnæan and Geological Societies, he founded the Greenwich Society of Useful Knowledge, and he was an honorary or corresponding member of numerous foreign societies. He was deputy chairman of the committee of the animal and vegetable substances of the Exhibition of 1861, and a juror of the educational section of the exhibition of 1862. He took an active part in questions of public importance of his day, such as slavery, emancipation, prison discipline, abolition of imprisonment for debt, sanitary and municipal organizations, the decimal system, public education, extension of the opening of public institutions, &c. His *Works*—Dr Gray commenced to publish in 1820, and continued till the year of his death. He began with an *Illustration of the Improvements in Comparative Anatomy and Zoology* in 1818, and ended with a paper "On the Madagascar River-Hog (*Potamocheirus*), and on the skulls of the three species of the genus," *Ann. N. H.*, x, 1875. The titles of the books, memoirs, and miscellaneous

papers written by him, accompanied by a few notes, fill a pretty printed list of 56 octavo pages. The more important of the books, besides those already mentioned, are—*Synopsis of the species of the class Mammalia*, 1827 (Giffith's *Critic*, vol. v.), *Illustrations of Turtin Zoology*, 2 vols., 1830-33, *A Synopsis of the species of the class Reptiles*, 1830, *Reptiles*, 1 vol., 1831, *Reptiles*, 1831-45, *Synopsis Reptilium*, 1831, *A Descriptive Catalogue of Recent and Fossil Shells*, 1832, *Turtin's Manual of the Land and Freshwater Shells of the British Islands* (new ed.), 1810, *List of the Specimens of Mammalia in the British Museum*, 1815, *Catalogue of Minerals*, 1814, *Systematic Catalogue of British Land and Freshwater Shells*, 1814, *Catalogue of Specimens of Lizards*, 1815, *Glancing from the Aegean and Aegean of Knowledge Hall* (compounded at the request of the British Museum), 1815, *List of the genera of recent Mollusca*, 1817, *List of Osteological Specimens*, 1817, of *British Sponges*, *Radiated Animals* (*Crustacea*), of *British Radiata*, *serpents*, 1818, *Catalogue of Mollusca*, 1818-50, *Catalogue of Reptiles* (*Serpents*), 1819, *Catalogue of Fish* (*Chondrocyti*), 1819, *Catalogue of Mammalia* (*Carnivora*), 1819, *Fossil Quadrupeds*, 1819, 1852, *Catalogue of Amphibia*, 1850, *Catalogue of Eocene Mollusca*, 1850-53, *List of Fish* (*Chondrocyti*), of *British Fish*, *serpents*, 1851, *List of British Mollusca* and *Shells*, 1851, *Catalogue of Echinodermata*, 1851, *Catalogue of Placodermata* (with L. Pfeiffer), 1852, *Catalogue of Fish collected and described by L. J. Gray*, 1854, *Catalogue of Shells* (*Reptiles*), 1855-72, *Catalogue of the recent Echinodermata*, 1855, *Catalogue of Pulmonata* (with L. Pfeiffer), 1856, *Guide to the Collection of Mollusca*, 1859, *Catalogue of Aporid Fish*, by Dr. T. J. Kump, translated and edited by Gray, 1859, *Catalogue of Annelida*, 1857, *Systematic arrangement of figures of Conchylia and Bivalves*, 1857, *List of Mollusca*, 1858, *Monograph of the genus Conchylia*, (with W. G. C. Smith), 1861, *Salisbury's Genera of Plants*, edited by Gray, 1866, *Catalogue of Seals and Whales*, 1866-71, *Catalogue of Species of Seals*, 1868, *Synopsis of species of Whales and Dolphins*, 1868, *Catalogue of Cetaceans*, 1868, *Catalogue of Mollusca*, 1868, *Catalogue of Mollusca*, 1869, *Catalogue of Mollusca*, 1869, *Catalogue of Mollusca*, 1870, *Tortuaries, Peripatus, and Tortuaries*, 1872 (re-edited), *Hand list of Seals, Mooses, Sea Lions, and Sea-Bears*, 1871.

GRAY, THOMAS (1716-1771), the author of the celebrated *Elegy written in a Country Churchyard*, was born in Cornhill, London, December 28, 1716. His father, Philip Gray, an exchange broker and scrivener, was a wealthy and nominally respectable citizen, but he treated his family with brutal severity and neglect, and the poet was altogether indebted for the advantages of a learned education to the affectionate care and industry of his mother, whose maiden name was Antrobus, and who, in conjunction with a maiden sister, kept a millinery shop. A brother of Mrs Gray was assistant to the master of Eton, and was also a fellow of Pembroke College, Cambridge. Under his protection the poet was educated at Eton, and thence went to Peterhouse, Cambridge, attending college from 1734 to September 1738. At Eton he had as contemporaries Richard West, son of the lord chancellor of Ireland, and Horace Walpole, son of the triumphant Whig minister, Sir Robert Walpole. West died early in his 26th year, but his genius and virtues and his sorrows will for ever live in the correspondence of his friend. In the spring of 1739 Gray was invited by Horace Walpole to accompany him as travelling companion in a tour through France and Italy. They made the usual tour, and Gray wrote remarks on all he saw in Florence, Rome, Naples, &c. His observations on arts and antiquities, and his sketches of foreign manners, evince his admirable taste, learning, and discrimination. Since Milton, no such accomplished English traveller had visited those classic shores. In their journey through Dauphiné, Gray's attention was strongly attracted by the wild and picturesque site of the Grande Chartreuse, surrounded by its dense forest of beech and fir, its enormous precipices, cliffs, and cascades. He visited it a second time on his return, and in the album of the mountain convent he wrote his famous *Aleppo Ode*. At Reggio the travellers quarrelled and parted. Walpole took the whole blame on himself. He was fond of pleasure and amusements, "intoxicated by vanity, indulgence, and the insolence of his situation as a prime minister's son,"—his own confession,—while Gray was studious, of a serious disposition, and independent spirit. The immediate

cause of the rupture is said to have been Walpole's, distinctly opening, reading, and re-reading a letter addressed to Gray, in which he expected to find a confirmation of suspicions that Gray had been writing and occasionally to some friends in England. A partial reconciliation effected about three years afterwards by the intercession of a lady, and Walpole welcomed his youthful ex-patriate long with a warm admiration and respect for his friend. Reggio Gray proceeded to Venice, and thence travelled to wards, attended by a *laissez de voyage*. He arrived in England in September 1741, having been absent about a year and a half. His father died in November, and found that the poet's fortune would not enable him to prosecute the study of the law. He therefore resided at Cambridge, and fixed his residence at the university. There he continued for the remainder of his life, with exception of about two years spent in London, where the treasures of the British Museum were thrown open. Cambridge he had the range of noble libraries. His leisure consisted in study, and he pursued with criticism the Greek and Roman poets, philosophers, historians and orators. Plato and the *Antilogia* he read and studied with great care, as it was for publication. He collected Greek chronology, added notes to Linnæus' other naturalists, wrote geographical descriptions on his travels, and besides being familiar with French and Italian literature, was a zealous encyclopaedist, student, and professor in architecture, botany, painting, and music, all departments of human learning, excepting mathematics, he was a master. But it follows that one so studious, critical, and so fastidious could not be a voluminous writer. A few poems include all the original compositions of the poet, the substance, as it were, of thirty years of study and contemplation, irradiated by bright and gleams of inspiration. In 1742 Gray composed his *Spring*, his *Ode on a Distant Prospect of Eton College*, his *Ode to Adieu city*,—productions which most read poetry can repeat from memory. He commenced a poem, *On the Alliance of Education and Government*, wrote only about a hundred lines. Every reader regrets that this philosophical poem is but a fragment in the style and measure of Dryden, of whom Gray was an ardent admirer and close student. His *Elegy written in a Country Churchyard* was completed and published in 1751. In the form of a *serpentine brochure* it circulated rapidly, four editions being exhausted the first year within the same period it also appeared in three volumes—the *Magazine of Magazines* (to February), the *Z Magazine* for March, and the *Grand Magazine of May* for April. This popularity surprised the poet. He sarcastically that it was owing entirely to the subject that the public would have received it as well if it had been written in prose. The solemn and affecting nature of the poem, applicable to all ranks and classes, no doubt and sale, it required high poetic sensibility and a cult taste to appreciate the rapid transitions, the figurative language, and lyrical magnificence of the odes, but elegy went home to all hearts, while its musical harmony, originality, and pathetic train of sentiment and rendered it one of the most perfect of English poems. Vicissitudes of taste or fashion have affected its popularity. When the original manuscript of the poem was offered for sale in 1854, it brought the almost incredible sum of £100. The two great odes of Gray, the *Progress of Poetry* and *Barry*, were published in 1757 and were not coldly received. His name, however, stood high, and on the death of the same year, he was offered the laureateship, but wisely declined. He was ambitious, however, of obtaining the more congenial and dignified appointment of professor of modern history in the university of Cambridge,

fell vacant in 1762, and, by the advice of his friends, he made application to Lord Bute, but was unsuccessful. Lord Bute had disengaged at the time of his son-in-law, Sir James Lowther. No one had heard of the tutor, but the Bute influence was all-pervailing. In 1765 Gray took a journey into Scotland, punctuating as far north as Dunkeld and the Pass of Killiecrankie, and his account of his tour, in letters to his friends, is replete with interest and with touches of his peculiar humour and graphic description. One other poem proceeded from his pen. In 1768 the professorship of modern history was again vacant, and the duke of Chillon bestowed it upon Gray. A sum of £400 per annum was thus added to his income, but his health was precarious—he had lost it, he said, just when he began to be easy in his circumstances. The nomination of the duke of Chillon to the office of chancellor of the university enabled Gray to acknowledge this favour conferred on himself. To thought it better that gratitude should sing than expectation, and he honoured his grace's installation with an ode. Such occasional productions are seldom happy, but Gray preserved his poetic dignity and select beauty of expression. He made the founders of Cambridge, as Mr Hallam has remarked, "poes before our eyes like shadows or a magic glass." When the ceremony of the installation was over, the poet-professor went on a tour to the lakes of Cumberland and Westmoreland, and few of the beauties of the lake country since so famous escaped his observation. This was to be his last excursion. While at dinner one day in the college hall he was seized with an attack of gout in his stomach, which resisted all the powers of medicine, and proved fatal in less than a week. He died on the 30th of July 1771, and was buried, according to his own desire, beside the remains of his mother at Stoke Poges, near Slough in Buckinghamshire, in a beautiful sequestered village churchyard that is supposed to have furnished the scene of his elegy.¹

The literary habits and personal peculiarities of Gray are familiar to us from the numerous representations and allusions of his friends. It is easy to fancy the recluse poet sitting in his college chambers in the old quadrangle of Pembroke Hall. His windows are ornamented with mignonette and choice flowers in China vases, but outside may be discerned some iron-work intended to be serviceable as a fire-escape, for his is a house of fire. His furniture is neat and select, his books, rather for use than show, lie disposed round him. He has a brass-bed in the room. In one corner of the apartments is a trunk containing his deceased mother's dresses, carefully folded up and preserved. His fastidiousness, bordering upon offensiveness, is visible in his gate and manner,—in his handsome features and small well-dressed person, especially when he walks abroad and seeks the author and hard student in

"the gentleman whosometimes writes for his amusement." He writes always with a crow quill, speaks slowly and sententiously, and shuns the crew of dissipated college idlers who call him "a pig," and seek to annoy him. Long mornings of study, and nights feverish from ill-health, are spent in those chambers, he is often listless and in low spirits, yet his natural temper is not desponding, and he delights in employment. He has always something to learn or to communicate, some sally of humour or quiet stroke of satire for his friends and correspondents, some note on natural history to enter in his journal, some passage of Plato to unfold and illustrate, some golden thought of classic inspiration to inscribe on his page, some bold image to toss down, some verse to retouch and harmonize. His life is on the whole innocent and happy, and a feeling of thankfulness to the Great Giver is breathed over all.

Various editions of the collected works of Gray have been published. The first, including memoirs of his life and his correspondence, edited by his friend, the Rev W. Mifson, appeared in 1772. It has been often reprinted, and forms the groundwork of the editions by Milnes (1811) and Mitford (1816). Mr Mitford, in 1819, published Gray's correspondence with the Rev. Newton Robinson, and in 1851 his correspondence with Mason, from which Mr. Hall had made only a partial selection in his memoirs of Gray. A second edition of the correspondence with additional notes was published in 1855.² (A. O. A.)

GRAYLING (*Thymallus*) are fishes belonging to the family of *Salmonideæ*, which live in the rivers and the gravelly (Gravel) in heavy scales of considerable size, and a narrow mouth with very small teeth. They are distinguished by their large, wing-like, dorsal fin. Only a few species are known, which inhabit clear streams of the north of Europe, Asia, and North America. The best known are the "Poisson bleu" of the Canadian voyageurs, and the European species, *Thymallus vulgaris* (the *Aesh* or *Aesche* of Germany, *Ombi* of France, and *Zemola* of Upper Italy). This latter species is esteemed on account of its agreeable colour (especially of the dorsal fin), its well-flavoured flesh, and the sport it affords to anglers. It is very fastidious in the choice of the rivers it inhabits. In England it is found in the Test, the Avon, the Dove, the Lug, the Wye, the Irt, the Teme, the Churn, the Edder, the Trent, the Don, the Ure, the Wharfe, the Tyne, the Ribbles, and the Derwent, but it is not found either in Scotland or in Ireland. It is more generally distributed in Scandinavia and Russia, and the mountain streams of central Europe southwards to the Alpine waters of Upper Italy. Specimens attaining to a weight of four pounds are very scarce. See *ICHTHYOLOGY*.

GRAZIALEMA (the Roman *Zuculiterium*), a town of Spain, in the province of Cadiz, is situated on the great road from Cadiz to Ronda, 60 miles E N E of Cadiz. It stands in a very strong position on a rocky hill, and to capture it was reckoned one of the chief feats of the *esfuerzo* Rodrigo Ponce de Leon. It possesses three hamlets, a parish church, and a convent. The manufactures are chiefly woollen, linen, leather, and soap, and there is considerable trade in sheep and swine from the neighbouring parts of the same name. Inscriptions and other Roman antiquities still exist in the town. The population is about 6000.

GRAZZINI, ALESSANDRO MARCESCO (1603-1583), an Italian author, was born at Florence, March 22, 1603, of good family both by his father's and mother's side. Of his youth and education all record appears to be lost, but he probably began early to practise as an apothecary. In 1640 he was one of the founders of the Academy of the Humid (dell' Umidi), and about forty-two years after was he took a prominent part in the formal establishment of the more famous Accademia della Crusca. In both societies he

¹ A claim has been put up for the church of St. Gryston, about two miles from Cambridge, the great bell of St. Mary's having for the "curfew." But Stoke Poges is more likely to have been the spot, if any individual lived in the neighbourhood. It is a village, has a church, and a mother receding there, and his wife was married in the church of the place. Gray's epitaph on his mother is a Christianized, not only by the tenderness with which he always regarded her memory, but by his style, and by the style. It is a beautiful village, his aunt and mother receding there, and his wife was married in the church of the place. Gray's epitaph on his mother is a Christianized, not only by the tenderness with which he always regarded her memory, but by his style, and by the style. It is a beautiful village, his aunt and mother receding there, and his wife was married in the church of the place.

² Beside his friend and wife lived deep the remains of Dorothy Gray, widow, the earliest female mother of many children, one of whom alone lived the maternal time to survive her. She died March 11, 1768, aged 72. She had lived to see the *Gray* poet, which was perhaps an ample recompense for his maternal cares and affection. Mrs Gray's will commences in a similar touching strain—"In the name of God, Amen. This is the last will and testament of Dorothy Gray to her son Thomas Gray." They were all in all to each other. The father's anxiety and neglect, thus returned circumstances, the sacrifices made by the mother to maintain him on at the university, her pride in the talents and conduct of that son, and the increasing gratitude and affection of the latter, mutual and equal objects of solicitude—these form an affecting but noble record in the history of genius.

² A volume of the original autograph letters of Gray addressed to Dr. Thomas Wharton, fellow of Pembroke Hall, Cambridge, and lately of London and Old Park, near Dullington, was added in 1877 to the Morgan library of manuscripts in the British Museum.

was known as *Il Lancia* or *Leuciscus*, and this pseudonym is still frequently substituted for his proper name. His tongue was what the French happily call a difficult one, and his life was consequently enlivened or disturbed by various literary quarrels. His Hamid brethren went so far as to expel him for a time from the society,—the chief ground of offence being apparently his ruthless criticism of the "Araméens," a party of the academicians who maintained that the Florentine or Tuscan tongue was derived from the Hobiw, the Childee, or some other branch of the Semitic. He was readmitted in 1666, when his friend Salvini was "consul" of the academy. His death took place on February 18, 1689. *Il Lancia* ranks as one of the greatest masters of Tuscan prose. His style is copious and flexible, abundantly idiomatic, but without any affectation of being so, it carries with it the force and freshness of popular speech, while it lacks not at the same time a flavour of academic culture. His principal works are *Le Cene*, a collection of stories in the manner of Boccaccio, and a number of prose comedies, *Lo Geloso*, *La Spiazzata*, *I Parentadi*, *La Fregata*, *La Sibilla*, *La Pincocchia*, *L'Argoglio*. The stories, though of no special merit as far as the plots are concerned, are told with verve and interest. A number of miscellaneous poems, a few letters, and *Four Orations to the Cross* complete the list of Giassani's extant works.

He the editor of *Le Vite di Bami*, collected *Trattato di Gram.*, *Lessi*, *Manuale*, & *Oratio Canonizandulchi*, *avanti per Fieri e dal tempo del magnifico Loren o del Medici fino all' anno 1569*. In 1868 Adamo Mosca published in his *Trattato per la biblioteca di Parigi* three "novelli," by Giassani, from a MS. of the 16th century in the "Comune" of Perugia, and in 1870 a small collection of those poems which have been left unpublished by previous editors appeared at Poggibonsi, *Alcune poesie inedite*. See Paolo Fanfani's "Vita di Lancia," prefixed to his edition of the *Opere di A. Giassani*, Florence, 1887.

GREAT BRITAIN AND IRELAND, THE UNITED KINGDOM OF, has been since January 1, 1801, the official title of the political unity composed of England, Scotland, and Ireland. Great Britain was employed as a formal designation from the time of the union of the kingdoms of England and Scotland in 1707. Although the name (which apparently had its origin in Britannia Major, the name given to the island to distinguish it from Britannia Minor or Brittany) had, in earlier times, been often used both by English and by foreign writers, especially for rhetorical and poetical purpose, it was not till after the accession of James I that it became a recognized part of the royal style. Its adoption was due to the king himself, who was anxious to give expression to the fact that he was sovereign of the undivided island, and not only of England or Scotland. As early as 1659 the Scottish Congregation had formally proposed through Matthew the union of the two crowns, and the adoption of the name of Great Britain for the common country (Toilet, 1, "Mém. Caillé & M. de la Mothe," Dec. 20). But in England the innovation at first met with great opposition. Various objections, sentimental and practical, were urged against it in parliament, and the judges, when appealed to by the king, declared that the adoption of the title would invalidate all legal processes. At length, on the 20th October 1603, the king, weary of the discussion, cut the knot by assuming the title by royal proclamation, and in due course the inscription "J D G Mag Brit F et H Rex" appeared on his coins. The proclamation declared that Great Britain was "the true and ancient name which God in his covenants, in all maps and chartes wherein this ile is described, and in ordinary letters to himselfe from divers foreign princes, warranted also by authentical charters, or emplacements under seals, and other records of great antiquitie." In November 1604 we find the king instructing the Lords Commissioners of the Gunpowder Plot

to try and discover if the prisoner was the author of a most "cruel psequit" against him for assuming the name of Britain. For further details see *Chronica of State Papers*, *Domestic Series*, and *Spedding, Letters and Life of Lord Bacon*, vol. iii.

GREAVES, JOHN (1602-1632), a mathematician and antiquary, was the eldest son of John Greaves, rector of Coleman, near Aylesford in Hampshire, and was born in 1602. He was educated at Balliol College, Oxford, and in 1630 was chosen professor of geometry in Gresham College, London. After travelling in Europe, he in 1637 visited the East, where he collected a considerable number of Arabic, Persian, and Greek manuscripts, and made a more accurate survey of the pyramids of Egypt than any traveller who had preceded him. On his return to Europe he visited a second time several parts of Italy, and during his stay at Rome instituted inquiries into the ancient weights and measures. Soon after his arrival in England, he was appointed to the Savilian professorship of astronomy at Oxford, but he was deprived of his Gresham professorship for having neglected its duties. In 1648 he lost both his fellowship and his Savilian chair on account of his adherence to the royalist party. But his private fortune more than sufficed for all his wants till his death in 1632.

Besides his papers in the *Philosophical Transactions*, the printed works of Greaves are *Pyramidologia antiqua, or a Discourse of the Pyramids in Egypt*, 1639, *A Discourse on the Romans Foot and Measure*, 1640, and *Elementa Lingue Persicæ*, 1640. His most curious work was published in 1787 by J. Smith, with a biographical notice of the author. See also Smith's *Vita quoniam danti creditur*, and W. H. Greaves's *Professor*.

GREBE (French *Grèbe*), the generally accepted name for all the birds of the family *Podiceps podiceps*,¹ belonging to the group *Pygopodes* of Illiger, members of which inhabit almost all parts of the world. Some systematic writers have

Great Crested Grebe

distributed them into several so-called genera, but, with one exception, these seem to be insufficiently defined, and here it will be enough to allow but two—*Latham's Podiceps* and the *Cento opoma* of Meuschen Scholer and Salvini. Grebes are at once distinguishable from all other Water-larks by their

¹ Often, but erroneously, written *Podipode*. The word *Podiceps* being a contracted form of *Podiceps* (of *Græce*), *podis* for *podice*, *podiceps*, 1564, p. 430, note), a combination of *podis*, *podice*, and *pes*, *podis*, the latter compounds must be in accordance with the derivation.

very short body, and the poemal structure of their feet, which are not only placed far behind, but have the two flattened and elongated toes furnished with broad lobes of skin.

In Europe we have five well-marked species of *Podiceps*, the commonest and smallest of which is the very well-known Dabchick of our ponds, *P. fluitans* or *minor*, the Little Grebe of ornithologists, found throughout the British Islands, and with a wide range in the Old World. Next in size are two species known as the Eared and Horned Grebes, the former of which, *P. nigripollis*, is a visitor from the south, only occasionally showing itself in Britain, while the latter, *P. auritus*, has a more northern range, breeding plentifully in Iceland, and is a not uncommon winter-visitor. Then there is the large Red-necked Grebe, *P. grispenae*, also a northern bird, and a native of the subarctic parts of both Europe and America, while lastly the Great Crested Grebe, *P. cristatus*, or Quaint—known as the Loon on the river and banks of East Anglia, and some other parts of England, is also widely spread over both Worlds, and though apparently not found within the tropics, is known in the extreme south as a native of Australia and New Zealand. North America is credited with seven species of Grebes, of which three (*P. cristatus*, *P. macropus*, and *P. auritus*) are admitted to be specifically inseparable from those already named, and two (*P. cornutus* and *P. californicus*) appear to be but local forms, the remaining two (*P. tomensis* and *P. melanotos*) may, however, be accounted good species, and the last differs so much from other Grebes that many systematists make it the type of a distinct genus, *Polydymbus*. South America seems to possess four or five more species, one of which, the *P. macropus* of Mr Gould (*Proc. Zool Society*, 1858, p. 220), has been deservedly separated from the genus *Podiceps* by Messrs Solari and Salvin (*Exot. Ornithology*, p. 189, pl. xcv), owing to the form of its bill, and the aberrant condition of its wings, which seem to render it absolutely flightless. Like Titicaca in Bolivia, so far as is known at present, its only habitat. Grebes in general, though averse from taking wing, have much greater power of flight than would seem possible on examination of their alar organs, and are capable of prolonged aerial journeys. Their plumage is short and close. Above it is commonly of some shade of brown, but beneath it is invariably white, and so glossy as to be in much request for muffs and the trimming of ladies' dresses. Some species are remarkable for the crests or tufts, generally of a golden-chestnut colour, they assume in the breeding season. *P. auritus* is particularly remarkable in this respect, and when in its full nuptial attire presents an extraordinary aspect, the head (being

surrounded, as it were, by a mass of aurole, such as that with which painters adorn saintly characters), reflecting the rays of light, glittering with a glory that passes description. All the species seem to have similar habits of nidification. Water-weeds are pulled from the bottom of the pool, and piled on a convenient foundation, often a semicircular growth of bog-bean (*Menyanthes*), till they form a large mass, in the centre of which a shallow cup is formed, and the eggs, with a chalky white shell almost equally pointed at each end, are laid—the parent covering them, whenever she has time to do so, before leaving the nest. Young Grebes are beautiful objects, clothed with black, white, and brown hair, disposed in streaks, and their bill often brilliantly tinted with orange or yellow. When taken from the nest and placed on dry ground, it is curious to observe the way in which they progress—using the wings almost as fore-feet, and suggesting the notion that they must be quadrupeds instead of birds. In water, however, they equal if not surpass their parents in the power of diving, which is a special accomplishment of all Grebes. (18)

GRECO, El. Domenico Theotocopi, commonly called El Greco, was a native of Greece, where he was born about the year 1545. He appears to have studied art at Venice, where it is alleged that Titian was his master. The date of his removal to Spain is unknown, but in 1577 we find him at Toledo, engaged on one of his instantly famed paintings, that on the painting of the raiment of Jesus. Until now he had been content to follow closely in the footsteps of the Venetian school, and he is generally admitted in his earlier works frequently to have approached the style of some of its best representatives, but in 1579, having been summoned, along with other artists of repute, by Philip II. to contribute to the decoration of the Escorial, he began to aim at greater originality of style with very unfortunate results. The first work in his new manner, having for its subject the martyrdom of St. Maurice, was executed in 1579, in this, as in all his subsequent productions, a dull ashen monotony of colour combined with stiff and unnatural drawing to produce an effect which is at no time very pleasant, and is sometimes absolutely repulsive. El Greco, however, continued to be held in considerable repute in the peninsula, sons in his honour are to be found in the writings both of Gorgora and Pallavicino, and he became the founder of a school in which many of the disciples excelled their master. He practised sculpture and architecture as well as painting, and is said by Pucheco to have written with great learning and ability upon all these arts, none of his books, however, have come down to our time. He died at Toledo in 1625.

GREECE

PART I—GEOGRAPHY AND STATISTICS

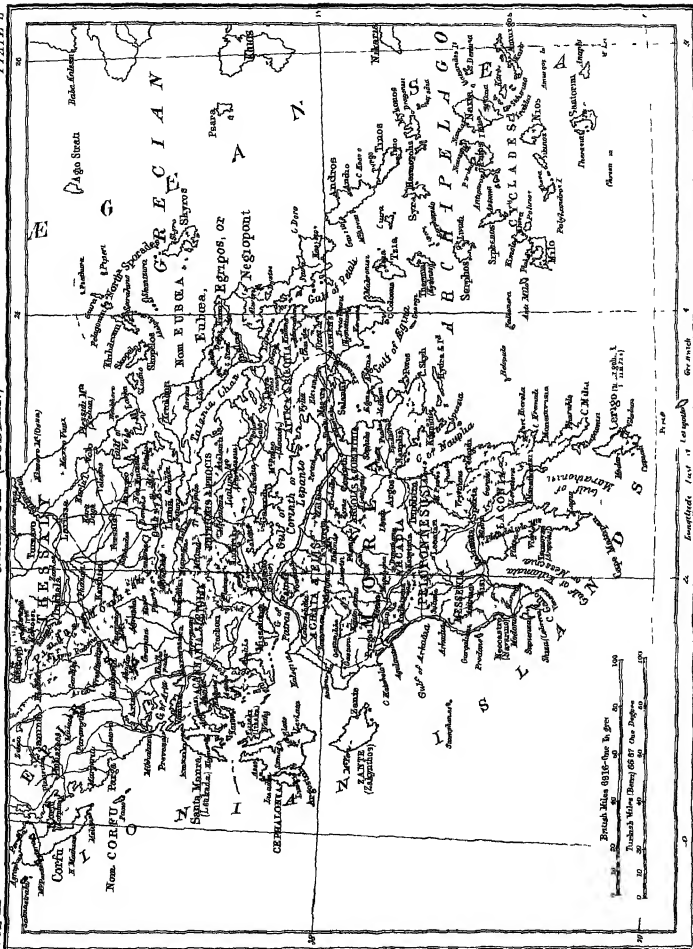

GREECE is a European kingdom, occupying the southern portion of the most easterly of the three peninsulas which Europe projects into the Mediterranean. By its own inhabitants it is called Hellas, as it was also in antiquity, and the name Greece, by which in one form or other it is known in most European languages, was given to it by the Romans, and was not used by any Greek writer, so far as we know, before Aristotle. Why the Romans called it so is an obscure point, but the most probable and usually accepted explanation is that they named their first knowledge of the country from a tribe in the north-west of Greece who were called Greci (Γραικοί), and that they accordingly gave the name of that tribe to the whole country. The name Greece or Hellas has been applied at different times to territory of widely different extent. At first Hellas denoted

nothing but the spot in Thessaly where the tribe of Hellenes dwelt, and in later times, after Philip of Macedon obtained a seat at the Amphictyonic council, it meant the whole peninsula south of the Balkan mountains (Hemus) including Macedonia and Thrace, but at the period of its greatest distinction it excluded those two regions, and was restricted to the part of the peninsula to the south of the Cambanian range and the islands of the surrounding seas. Its ancient limits, however, cannot be rigidly defined, for (1) its northern frontier seems never to have been precisely settled, some writers excluding Thessaly which was generally taken in, and others including part of Epirus which was generally left out, and (2) the name Hellas expressed not so much a geographical as an ethnological unity. It was the country of the Hellenes. Wherever Greeks settled

and II

Extent of
ancient
Greece
Plate I

there was Hellas, and a Greek colony in Sicily or Africa was thought to participate as essentially in all that constituted Hellas as either Attica or Lacedæmon. Still the name was usually applied to the land which formed the geographical centre of the race, of which the greatest length was 250 miles and the greatest breadth 180, and which had an area, exclusive of Epirus (4690 square miles) but including Eubœa (1410 square miles), of 21,131 square miles. This territory comprised (1) Northern Greece, all north of the Malææ (Zatonum) and Ambracian (Arte) Gulfs, (2) Central Greece, extending from these gulfs to the isthmus of Corinth, (3) the peninsula of the Peloponnesus (Morea), to the south of the isthmus, (4) the following islands,—Eubœa (Negropont) in the east, the Ionian Islands in the Ionian Sea on the west, Crete and Cyprus in the south, and the Cyclades and Sporades across the mouth of the Ægean from the south-east headlands of Attica and Eubœa. Continental Greece—i.e., all the country now specified, exclusive of the islands—consists of a series of natural cantons, hedged from one another and from the outer world by mountain ranges from 5000 to 8000 feet high, and so was almost by a physical necessity occupied in the times of its ancient political independence by seventeen separate states, none of which was larger than an ordinary English county. The whole eight states of the Peloponnesus covered less area than York and Lancaster together, and Attica, the most celebrated state of antiquity, was less than Cornwall. These states, which are noticed separately under the special headings, were—Thessaly, in North Greece, Acarnania, Ætolia, Locris, Doris, Phocis, Megaris, Boeotia, and Attica in Central Greece, and Corinthia, Sicyonia, Achaia, Elis, Messenia, Lacedæmon, Argolis, and Arcadia in the Peloponnesus.

Modern Greece is of smaller extent, and its limits are strictly determined by the arrangement between Great Britain, France, Russia, and Turkey, concluded at Constantinople on the 21st [9th] July 1832, which finally settled the question of frontier between Greece and Turkey. It left to Turkey the fertile Greek-speaking province of Thessaly and part of Acarnania, and fixed the northern boundary of Greece at a line running from the Gulf of Arte (Sinus Ambracius) to the Gulf of Volo (S. Pagasæus), keeping along the crest of the Othrys mountain range. The pass of Khlomo was to belong entirely to Greece, and the fort of Punta (Actum) at the southern head of the Gulf of Arte was to continue to belong to Turkey, though Greek vessels were required to have free entry into the gulf. The Ionian islands, consisting of Corfu (Corcyra), Paxos (Paxos), Santa Maura (Zante), Cephalonia, Thuri (Ithaca), and Zante (Zacynthum) on the west coast of Greece, and Cerigo (Cythra) on the south, which had remained under British protectorate for 50 years, were voluntarily ceded by Britain to Greece in 1864, after the accession of King George. Modern Greece is not more than two thirds the size of Scotland, it is 200 miles long from north to south, and 180 broad from east to west, and has an entire area of 19,363 square miles, of which 8288 square miles are in the Morea, 7658 in the northern part of continental Greece, 2500 in the islands of the Ægean, and 1007 in the Ionian Islands.

Its most obvious geographical peculiarity is its remarkable richness in mountains, bays, and islands, which give it unexampled natural defences, unusual maritime facilities, and quite a peculiar variety of climate, vegetation, and scenery. In this respect it but gathers into a smaller page and expresses in distincter type the structural peculiarities of the continent to which it belongs. In the complexity of its make and the variety of its natural features Greece excels every country of Europe, as Europe excels every continent of the world. No part of Greece is 40 miles

from the sea or 10 from the hills. Though not much more than half the size of Portugal, it has a coast-line greater than that of Spain and Portugal together, and that coast-line is broken everywhere into all manner of gulfs, and bays, and inlets, affording a rich supply of good natural harbours. The country is divided by its mountain chains into a number of independent parts, the capture of one of which by an enemy is but a single step towards possession of the whole. The small basins of its hills and between these hills maintained comparatively isolated populations, an account of the difficulty of inland intercommunication, and naturally developed that individuality of character, that local patriotism, and that political independence, which marked the ancient Greek communities. And the great variety of pursuit, interest, and stimulus which the geographical features of the country created could not fail to conduce to the uncommon mental vigour, quickness, and versatility which the people exhibited. The Greeks therefore owed their greatness largely to the country it was their fortune to dwell in.

The ruling features in the mountain system of ancient Greece—and, to a certain extent, in modern Greece also—is ^{the same} the great chain of Pindus, which takes its rise in the Balkans (Hæmus), and runs like a backbone through the entire length of the northern half of the peninsula, throwing out various branches to the east and the west on its way. At about 40° N lat. the Cambunians leave it and go east, forming the boundary between Macedonia (Roumelia) and Thessaly, and as they approach the coast they turn in a southerly direction at the lofty and famous Mount Olympus, the highest mountain in ancient Greece, and are continued at intervals, on the other side of the vale of Tempe, by Cesa (Kissavos), Pelion (Zagora), and the hills of Eubœa. At 39° the Othrys chain (Hællero), whose chief elevation is the conical Mount Veluch (Tymphrestus), is sent out also to the east, and forms the northern bulwark of the present kingdom. A little further south the Ceta range (Katoirothra) goes in the same direction, and reaches the Gulf of Zanteum (Malææ Gulf) at the celebrated pass of Thermopylæ. The Cambunian chain intersects Eubœa at Mount Læmon (Zygo), and thence westward the chain passes under the name of Ténarus and the Ceranian Hills (Montes Acroceramni) till it enters the sea at the Acroceramian promontory (Cape Linguetta). From the point of junction with the Othrys, the Pindus chain is continued southwards in a series of separate peaks—Parnassus (Iakura), Helicon, Othæron, Parnes, and Hymettus, on to the promontory of Sunium (Cape Colonna) in the south-east of Attica. Parnes divides Attica from Boeotia.

The mountains of the Morea have no connexion with the mountain system of Northern Greece, they do not run in chains, but rather cluster in knots. The most important of these are Ziria (Cyllene), Khlomos, Olimpos, and the range of Pentedaktylon (Taygetos), which stretches from the centre of Arcadia through the length of Lacedæmon to Cape Matapan (Ténarum), and is the most imposing of all the mountains of Greece. The hegemony of Sparta in the Peloponnesus is attributed by some to its possessing both sides of the chain. Its highest point is Mount St. Elias, called, like several other Greek mountains, after the prophet Elijah. None of the mountains of Greece is within the line of perpetual snow, though the tops of several are white for some months in the year. What is peculiar to Greece is not the presence of any one hill of pre-eminent height, but the great number it possesses of considerable and nearly equal elevation. Modern Greece has no summit so high as Olympus (9754 feet), but within its narrow area it has twenty-six hills above 3000 feet, of which eight are above 7000 feet—Parnassus (8088), Taygetus (7904), Tymphrestus (7610), Ceta (7071), the three summits of Oylène in Arcadia (7788), and Corax

in Euboea. The noted isthmus of Greece were Attica (1600 feet) which guards the isthmus, Ithome (2031 feet) at Messene, Larina (900 feet) at Argos, and the Acropolis (150) at Athens.

I n d u s t r y

Greece has few rivers, and the small, rapid, mud, as a rule, unbridled, as they could not be lying in a country where they rise in high mountains and have no space to grow in before they reach the sea. They are either perennial rivers or torrents, the white beds of the latter being dry in summer, and only filled with water after the autumn rains. The chief rivers (none of which are navigable) are the Hellas (Alpheus) in Peloponnesus, the Asopos Potamo (Acheron) in Euboea, and the Bonifis (Alpheus) and Vasiliko (Eurotas) in the Morea. Of the famous rivers of Athens, the one, the Ilissos, is only a chain of pools all summer, and the other, the Cephissus, though never absolutely dry, does not reach the sea, but is drawn off in numerous artificial channels to irrigate the neighbouring olive groves. The waters of both are clear and delicious to the taste. A frequent peculiarity of the Greek rivers is their sudden disappearance in sudden mean channels and reappearance on the surface again, such as gave rise to the fabled course of the Alpheus under the sea, and its emergence again in the fountain of Arethusa in Syracuse. Some of these clear streams—Katalaktes—are merely covered with herbage and gravel in the bottom, but others are large caverns through which the course of the river may be easily followed. Floods are frequent, especially in autumn, and natural fountains abound and gush out even from the tops of the hills. Agropyros rises high up among the peaks of Helikon, and Founes flows from the summit of Aegion. It is surprising that there are no waterfalls in Greece, the only one worth mentioning being the famous Styx in Attica, which has a fall of 500 feet. During part of the year it is lost in the snow, and it is at all times almost inaccessible. Lakes are numerous, but few of any size, and many merely marshes in summer. The largest are Thessalon in Thessaly, Copais in Boeotia, and Stympalia in Attica.

P l a n t s

The valleys are generally narrow, and the plains small in extent, deep basins filled in among the hills or more free at the mouths of the rivers. The principal plains are those of Thessaly (which is not in modern Greece), Boeotia, Messene, Argos, and Marathon. The bottom of these plains consists of an alluvial soil, the most fertile in Greece. In some of the mountainous regions, especially in the Morea, are extensive table-lands. The plain of Mantinea is 2000 feet high, and the upland district of Sparta, between Sparta and Tegea, is in some parts 3000 feet.

C o a s t

Strabo said that the guiding thing in the geography of Greece was the sea, which presses in upon it at all parts with a thousand aims. From the Gulf of Aiga on the one side to the Gulf of Volo on the other the coast is indented with a succession of natural bays and gulfs. The most important are the Gulfs of Aegina (Saronicus) and Lepanto (Cormathicus), which come in between the Morea and the northern mainland of Greece,—the first from the Aegean, the second from the Ionian Sea,—and are only prevented from joining their waters by the high land of the narrow isthmus of Corinth (3 miles wide). The outer portion of the Gulf of Lepanto is called the Gulf of Patras, and the inner part the Bay of Corinth, and a narrow bay on the north side of the same gulf, called the Bay of Salona, penetrates northwards into Phocis so far that it is within 24 geographical miles of the Gulf of Zeytoun on the north-east coast of Greece. The width of the entrance to the gulf of Lepanto is subject to singular changes, which are ascribed to the formation of alluvial deposits by certain marine currents, and their removal again by others. At

the time of the Peloponnesian war this channel was 1200 yards broad, in the time of Strabo it was only 850, and in our own day it has again increased to 2200. On the coast of the Morea there are several large gulfs, that of Acadia (Cynnaus) on the west, Kalamata (Messenian) and Kolokythia (Laconian) on the south, and Naxos (Argolic) on the east. Then between Euboea and the mainland lie the channel of Thessalon (Euboean Mare) and the channel of Egeus, which are connected by the strait of Egeus (Euripus). This strait, which is spanned by a bridge, is 130 feet wide, and is remarkable for the unexpected constancy of its tide, which has puzzled ancient and modern sailors. The current runs at the rate of 8 miles an hour, but continues only for a short time in one direction, changing its course, it is said, ten or twelve times in a day.

There are no volcanoes on the mainland of Greece, but everywhere traces of volcanic action and frequently violent actions of earthquakes, for it lies near a centre of volcanic agency, the island of Santorini, which has been within recent years in a state of eruption. There is an extinct crater at Mount Laphystium in Boeotia. The mountain of Metheon, on the coast of Aegina, was produced by a volcanic eruption in 282 B.C. An earthquake laid Thessalon in ruins in 1659, numerous destructions every where in Greece in 1868, and a third filled up the Corinthian gulf in 1870. There are hot springs at Thermopylae and other places, which are used for sanitary purposes. Various parts of the coast exhibit indications of upheaval within historical times. On the coast of Elis four rocky islets are now joined to the land, which were separate from it in the days of ancient Greece. There are traces of earlier sea beaches at Corinth, and on the coast of the Morea, and at the mouth of the Hellada. The land has gained so much that the pass of Thermopylae, which was extremely narrow in the time of Leonidas and his three hundred, is now wide enough for the motions of a whole army.

The whole chain of the Fintus and some of the mountain ranges of the Morea are composed of Primitive rocks,—granite, serpentine, porphyry, mica, and other schists,—but greater part of the country consists of Secondary formations, especially of a compact grey limestone, which hardens often into the purest marble. All Parnassus and Helicon consist of this rock. In the vicinity of Athens the limestone rests on mica schist, which prevails also in other parts of Attica, and in Euboea, Laconia, and the Cyclades. Clay slate is found in some districts, and coal, equal to two-thirds of an equal weight of Newcastle coal, is found at Kumi in Euboea, and of an inferior quality at Maroneia in Boeotia. Greece is not rich in minerals. Gold exists, but not in sufficient quantity to cover the expense of working. Copper is abundant, and silver, lead, iron, emery, antimony, cobalt, manganese, sulphur, and salt are found. Gypsum and porphyry are quarried. Marble is abundant, the chief kinds being the white marble of Pentelcus, of which the Parthenon was made, the blue marble of Hymettus, the green and red marble of the Morea, and the green and white of Caryste. In Mount Taygetos are beds of verd antique jasper.

The scenery of Greece excites the warmest admiration of all travellers, mainly from three causes—(1) its unusually rich variety, (2) its exquisite sensibility to every modification of the light of the sky, and (3) the graceful and almost severely classical outline of its hills.

The vegetation of Greece may be described as belonging to Vegeta four distinct zones. (1) Up to 500 feet above the sea is a region now growing corn, vines, olives, oranges, melons, pomegranates, and other fruits, (2) from 1500 feet to 2500 feet is the region of the oak, (3) from 2500 feet to 3000 feet is the region of the beech and pine, interspersed still with a few corn fields, (4) above 3000 feet is a sub-alpine region yielding only a few wild plants.

Most travellers are struck with the comparative scarcity of wood in Greece. But though most of the ancient forests have disappeared, none of the *silva* is still in ruins. Wooded trees are still a *diva* flower on 15 per cent of the area under forest in 1860, which is only 1 per cent in 1870. The most common trees are the oak, pine, walnut, chestnut, and olive are also abundant. The beach is said to be a median interval from the north, where it covers the whole of the Pindus range, to some places, as on Mount Pelion, which were covered with olive kinds of trees in historical times, the beach seems now to have driven them entirely out. The pine thrives in Messenia, and has a home even in Attica. Myrtle flourishes in the west, and oleaster and the vine are both common.

Animal

The wild animals are to be found occasionally in Greece are the bear, wolf, deer, lynx, wild cat, jackal, and fox. The wild goat, which is disappearing from the rest of Europe, finds its last asylum in some of the highest peaks of the Greek wilderness. Game is abundant,—red deer, fallow deer, roe, hares, rabbits. It is said that hares and rabbits never occupy the same island, except in the case of Andros, where the latter is found in the north and the rabbits in the south. The birds are the eagle, vulture, hawk, owl, hoopoe, egret, pochard, phalarope, bustard, p. bird, woodcock, nightingale, etc. Quails come in April. The domestic animals are the horse, ox, ass, mule, sheep, goats, pig, dog, and poultry. Foxgloves are only found in some few places, and mosquitoes and gnats are everywhere sources of annoyance.

Climate

The climate of Greece, which ancient writers praised for its equableness, presents to modern observers two peculiarities which do not possess that character. One is a greater intensity of heat in summer and of cold in winter than obtains in Spain, Italy, and other countries which lie within the same latitudes, and are even less open to the balancing influences of the sea. The probability is due to the exposure of the country to the cold winds from the snow hills on close proximity to it on the north, and to the oblique sunbeams from the south of Africa on the south. The other peculiarity is the remarkable level contrasts, and rapid transitions, which the climate manifests, and which is a natural effect of the diversity of the ground which configuration. The remark of Gail is often quoted, that in travelling through the More in March he found summer in Argolis, winter in Locria, and winter in and winter in without moving beyond a radius of 50 miles. There is great diversity in the rainfall in different parts of Greece. As a rule, rain is more prevalent in the north, which is the best, which is favorable for the fruiting of the hills of Elis and the eastern aspect of those of Argolis. Attica is the driest part of Greece, and Boeotia has still the heavy snow most temperate it had of old, and what is remarkable, the old contrast between the people of those two provinces, which was proverbial when both were Greek by blood, still holds good when they are both certainly Albanian, the Attians of the present day being still quick and lively, and the Boeotians dull and phlegmatic. According to statistics kept by Julius Schmidt, director of the observatory at Athens, and published in his *Beitrag zur physikalischen Geographie von Griechenland* (1864-70), there were in 1869 only twenty-five days on which enough rain fell to be measured by the rain gauge. The mean annual temperature of Greece is 64° Fahr. The coldest months of the year are January and February. Snow seldom falls in Athens. The coast is a considerable height in March, and is out in May. The olive buds in March, and almond are then in blossom. Winters are, however, severe on the highlands, and in some of the plains of the interior which are shaded from sun and sea by high hills. Dr. Kuss was named the mountains at the foot of Cithæron, in Boeotia, were confined to their houses sometimes for several weeks by snow. Kuss says the north wind blows ten months of the year, but Schmidt's statistics show that to be an error. There are really both northerly and southerly winds every month, though now the one is more prevalent and now the other. The bud winds (so called because they bring the buds of passage) are a periodical variety of the south-west, and blow for thirty days from the south-west, and for fifteen from the north-east winds from the north-east, which blow regularly about the time of the dog days, and temper the heat of that season in the whole region of the Archipelago. Columbus says they began on the 1st August and continue till the 8th, and Kuss, on the other hand, says they begin in July and blow for fifty-five days (*Atlas*, i. 386), but neither of these statements is borne out by Schmidt's figures. In 1869 the only winds which blew at Athens during July and August were north-east and south-west, and out of the sixty-two days the north-east blew for thirty-four, and the south-west for twenty-eight,—the north-east blowing twenty-two days in July and twelve in August, and the south-west nine in July and nine in August. Malin prevails largely from the neglect of drainage and the consequent escape of miasmas in many parts, and the malaric cause fever, which is very fatal among children, and leaves debilitating effects in the adults, and altogether imposes a very serious check on the growth of the population of the country.

The modern Greeks are of very composite origin, yet are inhabiting an extremely compact and homogeneous people. Out of twenty million and a half which constitute the present population of the country, only 67,911 speak any other language than Greek, and only 16,081 profess any other religion than the Orthodox, and all draw well together, glorying with one another in the same manner of a common divergence, and sharing in the same ambition of a great future. There are in the narrow bounds of Greece three distinct races, speaking different languages, wearing different costumes, observing different customs, and holding little social intercourse with one another. These races are the Greek, the Albanian, and the Wallachian. All three are probably of common blood, and in fact, the descent of each of them has been a very vexed problem in ethnology. But, on the whole, the suggestion of Freeman seems the most likely account of the matter,—that, taking them all in all, these three races are the direct representatives of the three races which occupied Greek territory at the time of its conquest by the Romans. Since that time their blood has certainly been mingled with other elements, but still substantially the base of the modern Greek is the ancient Greek, the base of the modern Albanian is the ancient Illyrian, and the base of the modern Wallachian is the ancient Thracian.

Of these races the least numerous in Greece is the Wallachian or Roumanian. They are found chiefly in the mountainous regions in the northern parts of Greece, on the slopes of Othrys, in the neighbourhood of Zaitoun, on the hills of Aetnania and Etolia, and even so far south as the banks of the Boeotian Cephissus. They pursue a nomadic shepherd life, wear black shaggy capotes made to imitate sheep skin, and speak Roumanian,—a modified Latin,—the language of their race, and also Greek, the language of the country. They belong to the Greek Church, and sometimes marry Greek girls, but almost never give their own daughters in marriage to Greeks. In 1861 Finlay says there were 50,000 Wallachians in the modern kingdom of Greece, but they are rapidly becoming completely Hellenized, and in 1870 there were only 1317 Wallachians in Greece who did not speak Greek. Most of the brigands that used to infest Greece were Wallachians.

The Albanians, Skripitars (i. e., Highlanders), or Armatists, occupy at present more than a fourth of modern Greece,—all Albania and Megara (except the capitals), most part of Boeotia and part of Locria, the southern half of Euboea, part of Argina and Andros, the whole of the islands of Salamis, Pinos, Hydra, and Spexia, and considerable districts in Argolis, Elicynna, Acadia, Laconia, Messenia, and Elis. They speak a language of their own, which certainly belongs to the Aryan family, but philologists are at a loss whether to count it an independent member of the family, or merely a corruption of one of the better known branches. In districts where they exist in small bodies they are losing their own tongue and adopting Greek, but in places like Attica and Hydria, where they exist in larger numbers, they still keep it up, and if the men understand Greek the women do not. In 1861 Finlay states there were 300,000 Albanians in Greece, and in 1870 there were only 37,598 left who did not speak Greek. The Albanians who dwell in Greece all belong to the Greek Church. They are mostly agriculturists, and seem to care little for political or professional life. They wear a peculiar dress, which was adopted by them mostly from the Slavs, and was regarded as the national costume of Greece after the Revolution,—a red fez, a silk jacket embroidered with gold, a white fustanella or petticoat, and gaiters.

The rest of the population, comprising the great bulk of it, are Greeks,—a people speaking the Greek language, practising the Greek rite, and claiming descent from the

ancient Greek race. This claim, which seems to rest usually on the obvious evidence of language, and features, was mainly contested on historical grounds, by Fallmerayer, who held that during the Slavonic occupation of the country the ancient Greeks were completely extirpated, and that the present inhabitants are purely Slavonic. By-antized. But his arguments have been conclusively confuted by Hoff, Finlay, and others, and it may be said to be now universally admitted that, while the blood of the population contains a considerable Slav admixture, its base is still that of the ancient race of Hellenes.

It is curious that the two sections of the population of Greece whom Fallmerayer noticed with the purest Greek descent—the Minoes, and the Tshakones, who inhabit the two mountain ranges of Laconia—also thought by Hoff to be the only two remnants of the Slavs, that still exist. The Tshakones, whose name is commonly supposed, contrary to all etymological analogy, to be a corruption of Laconia, speak a peculiar dialect of Greek, and still live very much by themselves. They now occupy only seven villages, and number 1500 families. The Minoes, celebrated by Byron, live in Maina, on the western mountain chain of Laconia. They also speak a peculiar dialect, and are remarkable for their personal beauty and independent spirit. Their houses are fortified keeps, and they were never subdued by the Turks. They practice the vendetta, but are simple and truthful above their neighbours.

Other nationalities are represented in Greece, but so slightly as hardly to be worth mentioning. They numbered only 28,126 in all in 1870. The Jews, who were never favoured by the Greeks, are found only in the Ionian Islands, where they obtained a footing during the British protectorate, and numbered, in 1870, 2338. Important remains of the old Venetian colonists still exist in the Ionian and some of the other islands.

In physique, the Greeks are generally tall and well made, of pelagic stature, with oval face, long and arched nose, fine teeth, and eyes full of animation. Obesity is unknown, and their form is supple, graceful in the movements, and remains erect and elastic till past the age of 70. The best physical types are to be found in the islands and in some parts of the Morea, and there, many travellers remark, you may meet every day in the streets or highways women and boys who might have formed the models of Phidias.

National
character

The national character of the Greeks is a matter upon which authorities take very contrary views, some idealizing them foolishly, and others depreciating them most unjustly. They seem to have the faults and the excellences of their famous ancestors. They have their quickness of parts and their moderation of character. They are ungovernable of mental activity, fond of excitement, as keen for discussion as in the days of Plato, and as eager after novelty as in those of Paul. Their thirst for knowledge is indeed quite remarkable, as well as their aptness to learn. Boys will put themselves to any discomfort in order to get to school, students at the university never missed a day from their classes during the Revolution of 1833, but regularly attended the lectures with the aims of the national guard in their hands, and domestic servants are often found in spare hours learning their letters or doing their sums. They excel in tact, in astuteness, in what Tuckerman calls the most distinctive thing about them—finesse, which degenerates often into cunning, that weapon of the weak which could not fail to be forged under their long Turkish oppression. They are contentious and very sunny in disposition, and entirely strangers to melancholy, so that both suicide and insanity are unknown among them. They are the most temperate of Christian nations, and the chastest. Though they make

a good deal of strong wine, they drink little, and they eat as sparingly as they drink. The common people live on one meal a day, and the richer on two, and an English labourer will consume at one meal what would serve a Greek family of six for the day. A little maize and vegetables steeped in oil make the staple fare. Their rate of illegitimacy is lower than that of any other European country, which may perhaps be ascribed to the fact that Greece is the only country in Europe where the males outnumber the females, and that this circumstance combines with the frugal habits of living of the people to encourage early marriages. In other countries from 3 to 22 per cent of the births are illegitimate, in Greece only 1.40 per cent are so. Two striking characteristics of the Greeks are their patriotism,—their local attachment to their country, which stands out in the stronger relief because it is a quality in which their neighbours the Turks are entirely wanting,—and their love not only of liberty but specially of equality. They are in spirit the most democratic European nation. They have no nobility—as of old, to be a Greek is itself to be noble, and Minshaf says that “every common mule-boy is a gentleman (*kipros*) and fully your equal, sitting in the room at meals, and joining in the conversation at dinner,” and such is their jealousy of social superlatives that he was often told by Greeks that the only reason why they tolerated a foreign king was that they could not endure to be under one of themselves. It is the same temper as ostracized Aristides, and doubtless it springs largely from their vanity and egotism, which even the most favourable witnesses own to be among their prominent faults. They have a deep belief, which they take no pains to conceal, in their own superiority over other nations, and the point in which they conceive their superiority more especially to dwell is in their intellectual gifts. There are two other qualities in which the Greeks are strong, and which, though they are often abused, are yet main agents in human advancement,—ambition and the love of money. These have given a stimulus to their commerce, and made them thrifty and saving. The faults of which the Greeks are oftenest accused are cowardice and dishonesty, and both charges are equally unwarranted. Their bravery was proved on many a field during the War of Independence. Dishonesty is not a national vice, though it seems certainly to be characteristic of the classes of Greeks who more than the rest are thrown under the observation of foreigners particularly the low mongrel Greeks of the Levant ports and the venal public officials of Greece, who have consequently helped to blacken the reputation of their countrymen in general.

The Greeks have few peculiar customs worth noting. Customs

Their national costume is now giving place almost universally to the less picturesque dress of the Franks. They still adhere to the unrefined calender, and their dates are accordingly calculated according to old style. They marry early—young women from thirteen years of age to fifteen, and young men from sixteen to twenty. The marriage is arranged by the parents of the parties, is in all cases a religious ceremony, and may be repeated by legal divorce. One is allowed to marry three times, but a fourth marriage is forbidden. The bride brings a dowry—houses, furniture, or money—and many unmarried girls wear their whole dowry in pieces of money as a head-dress. The prohibited degrees are those of canon law.

The population of Greece in 1879, when the last census was taken, was 1,872,775, or an average of 84 persons to the square mile. The islands are the most densely peopled portions of the kingdom, especially the Ionian Islands, which have a population of 231,174, or 229 to the square mile. In continental Greece the rate is only 59 per square mile, and in the Morea 89. Greece is more thinly peopled

than any country of Europe, except Russia and Sweden. The population has doubled since 1832. It was then (exclusive of the Ionian Islands) only 612,608 and it is now (also excluding the Ionian Islands) 1,448,601. The males outnumber the females in Greece by 82,385. The only reason we have seen assigned for this is that large numbers of the women go out of the country as domestic servants, and are not counted in the census, while sailors, who are also at work out of the country, are counted. But this seems an inadequate explanation, for in 1870 the number of sailors not present in the country was only 5180. The disproportion between men and women appears, too, to be increasing, for there were 50,408 more men than women in Greece in 1870, when the whole population was 220,000 less than it was in 1879. The average birth-rate for the four years 1870-73 was 1 in 34, the average death-rate for the same period was 1 in 45. The largest towns in Greece are—Athens, with a population in 1870 of 59,000, Piræus, with 26,000, Corin., with 24,000, Heliopolis or Syra, 21,000, Zante, with 20,500, Chalcis, 11,000, Sparta, with 10,700, and Argos, with 10,600.

The kingdom of Greece is an hereditary constitutional monarchy, descending by primogeniture from male to male, female succession being only allowed in the event of the absolute failure of legitimate heirs male. The title of the sovereign at first according to the convention of London, May 1832) was king of Greece, but it was altered by the conference of London, August 1833, to king of the Hellenes. The king attains his majority at eighteen years of age. Both he and the heir-apparent are required to belong to the Greek orthodox church, but a special exception is made for the present king, who is a Lutheran. The king receives an annual income of £52,179, of which £40,179 comes from the civil list, and £12,000 from personal donations of £4,000 from each of the three protecting powers. He has a palace in Athens—built by Otto at a cost of £600,000—and a summer residence at Corfu. The legislative power is shared by the king with a single chamber called the boule,—a house of representatives which is elected for four years by the people, its numbers cannot fall below 150, and amounted in 1873 to 138. The election is by universal (manhood) suffrage, protected by the ballot. The boule elects its own president, and its members are paid £9 a month during the session. The executive is vested in the king, who, however, is personally irresponsible, and rules by ministers chosen by himself and responsible to the legislature, in whose deliberations they also take part. They are seven in number, and their several departments of administration are—foreign affairs, home affairs, justice, finance, education and worship, army, and navy. A minister's salary is £428 a year. The king appoints all public officials,—civil, naval, and military,—sanctions and proclaims laws, calls and prorogues parliament, grants pardon or amnesty, confers money, and confers decorations. There are 18,860 public offices in the patronage of the ministry, and, as in America, a large number of them change hands with every change of administration. The effect of this in a country where politics is an open profession, and where there is a plethora of well-educated men who can find nothing to do, has been to poison political life to an unusual degree with the vice of place-hunting,—to create several active political parties in the state, which, instead of being the representatives of any policy or cause, tend too much to degenerate into mere rings of post-mortems, and conduce, by their constant strife, to an excessive frequency of ministerial crises which greatly checks the national progress of the country.

For purposes of local government Greece is divided into

13 nomarchies, under officers called nomarchs, whose duties correspond with those of the French préfets, the nomarchies are subdivided into 59 eparchies, under eparchs, corresponding to French sub-prefects, and the eparchies are further subdivided into 351 demarchies, under demarchs or mayors. The following is a list of the nomarchies, with their areas, populations, and capitals—

	sq Mils	Pop in 1870	Capitals
A In Northern Greece—			
1 Attica and Boeotia	2181	185,364	Athens
2 Eubœa	1774	95,136	Chalcis
3 Phthiotia and Phœtia	2059	128,440	Lamia
4 Acarnania and Aetolia	3025	138,411	Mitsolonghi
B In Mores—			
5 Achæia and Elis	1909	181,632	Patre
6 Arcadia	2028	148,905	Tripholiz
7 Locria	1678	121,116	Sparta
8 Messenia	1526	135,700	Andania
9 Argolis and Corinthia	1448	136,081	Nauplia
C In the Islands—			
10 Cyclades	926	182,020	Syria
11 Corfu	427	106,109	Corfu
12 Cephalonia	402	80,615	Argostoli
13 Zante	377	44,522	Zante

The demarchs are elected by the people for four years, the nomarchs and eparchs are elected by the Government without fixed terms. The nomarchs are assisted in the administration of the province by a council elected by universal secret suffrage for four years, which manages the police, roads, and other local business, and imposes the assessments. The local accounts must be sent once a year to Athens to be audited by a court of Government officials. The demarches vary in size, but, in 1861, out of 280 that then existed, only 67 were under 2000 in population, and only 7 above 10,000.

Greece has an admirable legal system, which is the one judicial good thing it has got from the Byzantines. It is based on system the old Roman law, with modifications drawn from the Bavarian and French. Liberty of person and domicile is inviolate, no one can be apprehended, no house can be entered, and no letter can be opened without a judicial warrant. Criminal and political offences and delinquencies of the press are tried by jury. The commercial code is identical with that of France. The civil law is administered by a supreme court of cassation (the Areopagus); 4 courts of appeal, 17 courts of first instance, with jurisdiction up to 800 drachmas, 191 judges of the peace, with jurisdiction up to 50 drachmas, or, with an appeal, to 800 drachmas, and 4 commercial courts (at Syra, Nauplia, Patras, and Corfu), with jurisdiction up to 800 drachmas. To be a judge, it is necessary to have graduated as doctor of laws at Athens or some other European university, a judge cannot hold any other salaried appointment at the same time except that of professor in the university. Judges are appointed by the crown, and are as yet removable. Criminal courts are held in connexion with those of the peace, of first instance, and of appeal, in the last the judicial authority is vested in a jury of twelve, with three accessory judges selected from those of the inferior courts, who apply the law in accordance with the jury's verdict. The crown is prosecutor in all criminal cases, and punishes as by fines, imprisonment, and, in the case of capital offences, death by guillotine. The prisons are extremely defective in construction and administration, except that of Corfu, improvements are often projected but constantly put off from want of funds to carry them out. There is no Habeas Corpus Act, and an accused person may be detained indefinitely before being brought to trial. Judicial commissions and extraordinary courts of judicature cannot be established under any pretext

The courts of law are open to the public, except when the interests of good morals or public order demand the contrary. Naval and military offences are tried by naval and military courts, and offences of ministers of the crown by special courts, in accordance with the constitution of 1861.

Crime is proportionately less common in Greece than elsewhere, for the people are more temperate, and, on the whole, more contented. The principal Greek crime is—, as we may happily now say, was—brigandage, the form of robbery which is natural to a mountainous and thinly peopled country without roads. According to the latest consular report, the country is at present completely free from brigands. But it will never be secure against their reappearance until it obtains good roads, which will operate against the brigands both by tending to increase the rural population and by affording better facilities for the capture of criminals.

Army. The strength of the Greek army on a peace footing was, at the census in 1870, 13,400, including upwards of 3000 conscripts, but since the Servian war with the Turks in 1876 the Government has resolved to raise it to 24,370, exclusive of 2508 mounted gendarmes. This, with the national guard and the reserves and volunteers, would make their total strength on a war footing over 150,000. The national guard is composed of all citizens capable of serving and under the age of 40; it is designed for purposes of defence only. The reserves consist of those who have served out their time in the regular army. The army is recruited by lot from all capable of serving, with the alternative, which is largely used, of providing a substitute, and the period of service is three years in the line, three years in the first reserve, and six in the second.

Navy. The navy consists of two small ironclads and a few wooden gunboats and vessels for coast-guard purposes, which are manned by 2650 men, mostly, as a rule, by conscription from the inhabitants of the coast, though volunteering is encouraged. The Greek flag is a white cross on blue ground—the Bavarian colors—and the Greek cross.

Religion. The religion of the people and of the state is that of the Orthodox Greek Church. In fact, the Greek rite is not only the national religion, but perhaps the deepest and most exclusive factor in the nationality of Greece itself. Men of Greek blood who do not belong to the Greek Church do not identify themselves with the Greek people. The Moslems of Crete were the stoutest oppressors the Greeks knew, and the Latins of Syros sided at the revolution with the Turks, yet both were of the purest Greek descent. And what makes the Greek and Slavonic and Wallach of the modern kingdom all equally Greek in their sympathies to-day is their common profession of the Greek rite. But all other religions are tolerated in Greece. There is a Moslem mosque at Chalcis, there is a Jewish synagogue at Corfu, and, whatever a man's religion may be, it entails on him in Greece no civil disabilities of any kind. A Catholic or a Mahometan may rise to the highest offices of state, both Turks and Jews are at present members of municipal councils, and Jews and Catholics are buried in the same cemetery with the Orthodox at Athens. The Church of Greece, which became virtually independent at the time of the revolution, was organized upon the model of the Russian Church. Its supreme power is vested in a synod consisting of five members, who are appointed annually by the king, and the majority of whom must be laymen. The metropolitan (archbishop of Athens) is *ex officio* president, two royal commissioners attend and deliberate without voting, and the synod's resolutions require to be confirmed by them in the king's name. In all purely spiritual matters the synod has entire independence, but on questions having a civil side—as marriage,

divorce, excommunication of laymen, the appointment of feasts and fasts, and the religious censorship of the press and of religious pictures,—it can only act in concert with the Government. Excluding the Ionian Islands, which have five archbishops, there are eleven archbishops and thirteen bishops in Greece, who are chosen by the king out of a list of three candidates presented by the synod, and can only be deposed by common consent of king and synod, and in conformity with canon law. The clergy numbered 8103 in 1861. The immense majority of the population belongs to the Greek Church. In 1870 the number of other Christians in Greece was 37,585; most of whom were Roman Catholics, of Jews, 2532, and of all other religious, 917. There are two Roman Catholic archbishops and four bishops. The revenue from the property of the Greek Church in 1877 was £10,571. The prelates receive a salary from the state,—the bishops £145, and the archbishops £180. The inferior clergy receive none, but are entirely dependent on the fees they earn for various spiritual services and superstitious observances,—paying for the sick, exorcising the evil eye, consecrating a new house or fishing boat, or purifying one bought from a Turk. There are 1600 monks and 1600 nuns in Greece.

Popular education is widely diffused in Greece. It was Eduard Reclus who first noticed the newly-liberated people, and has been justly and justly fostered ever since, till they are now an exceedingly complete national system of education, which is perhaps the most striking product of the new kingdom. The latest statistics we have on the subject are those of the year 1872, given in Watson's report of that year (*Reports of H.M. Secretaries of Embassy and Legation, No. 1*, 1872). From these figures we learn that there were then 1141 primary or domestic schools, 130 grammar or Hellenic schools, 7 gymnasia, and finally, the crown of the whole, the university of Athens, besides 6 nautical schools, a polytechnic school, 4 theological seminaries of the Greek Church, and various private institutions maintained by Catholic or Protestant societies. At the primary schools, the usual elementary branches only are taught,—reading, writing, arithmetic, the catechism, grammar, history, geography, natural history, agriculture, and drawing. In the Hellenic schools instruction is given besides in the least difficult of the ancient Greek authors, and in the gymnasia, a more thorough acquaintance is made with ancient Greek, and with Latin and French, mathematics, logic, anatomy, physics, and natural history. The teachers of the primary schools are educated at a training institution in Athens, those of the Hellenic schools must be holders of a university, and those of the gymnasia must have the degree of Ph.D. The primary schools are maintained at the expense of the commune, with a subsidy, in certain particular cases, from the state. The total amount spent by the communes for this object comes to about one-sixth part of their income, or over £40,000 in all, and the whole Government grant for primary education in 1873 was £4171. At these schools a small fee is charged, running from 1d to 3d a month, from all who are able to pay it. The grammar schools, the gymnasia, and the university are maintained entirely by the state, the expense in 1877 exceeding £35,000 for the two classes of secondary schools, and £18,000 for the university, at these schools and the university education is entirely gratuitous, and is furthermore encouraged by the existence of various exhibitions for meritorious pupils, won by competition. The university was erected at a cost of £10,000, raised by private subscription from Greeks all over the world, and is furnished with excellent laboratories and museums, a library of 150,000 volumes, medical hospitals, an astronomical observatory, and a botanical garden. It has 4 faculties—arts, medicine, law, and theology—52 pro-

fessors, 12 fellows; and, after a curriculum of 1 year, confers the degree of licentiate and doctor, which are indispensable for those who contemplate becoming lawyers, medical men, or teachers in the higher schools. It was opened in 1835 with 53 students, in 1854 it had 613, it now has 1400. In 1872 it had 1344,—of whom 26 were students of theology, 622 of law, 493 of medicine, 120 of arts, and 53 of pharmacy. The small number of theological students is partly accounted for by the existence of four other theological seminaries in Greece, supported by private funds,—one at Athens and three in the provinces,—and partly by the scandalous neglect of clerical education that obtains in Greece. In 1867 there were only 115 students at these four theological seminaries. A large proportion of the students at the university have always been foreign Greeks, for professional men are trained there not only for Greece itself but for the whole region of the Levant. Out of the 1244 students who attended in 1872, 219 were Greeks from foreign parts,—124 of these being students of medicine, 66 of law, and 6 of theology. No one is admitted as a student who has not completed his education at a gymnasium. The salary of a professor hardly amounts to £200 a year. There is no school inspection beyond that of the demarch.

Education is by law compulsory for children from seven to twelve years of age, but this law is not enforced, for it does not require to be, and the results of education in Greece are the more remarkable as being the fruits of what is practically purely voluntary attendance. Every eighteenth person in Greece is at school, in Russia only every seventy-seventh is so. In 1872 the total number of pupils was 81,197,—of whom 65,111 were males and only 16,086 females. Boys and girls are taught at separate schools, of the primary schools, 942 are for boys, with 1009 male teachers and 52,943 pupils, and only 199 for girls, with 221 female teachers and 11,036 pupils. The Hellenic schools and gymnasia are for boys only, and in 1872 had 6095 and 1942 pupils respectively. There are, however, various private schools for girls, with an aggregate attendance of 5000. These figures show that there is a serious defect in female education, for which neither the Government of Greece nor the people have due solicitude. It ought to be mentioned, however, that there is one phase of female education in which Greece is in advance of many other European countries, for the medical school of Athens is open to female students, who numbered 42 in 1879.

Indus-
tries

We have no exact statistics as to the numbers engaged in each branch of industry severally, but Bikelas gives in the *Journal of the Statistical Society of London* for 1868 an estimate for the year 1861, according to which nearly half the population (49·37 per cent.) were agriculturists and shepherds, and more than a third of the remainder (or 18·66 per cent. of the whole population) in the liberal professions. 13·87 per cent were engaged in industrial pursuits, 8·43 per cent in trade, 5·40 per cent were domestic servants, and only 4·27 per cent were persons of independent means. Government officials and their families comprise a twelfth part of the population. There is great want of employees with considerable capital, and the amount of labour done and wages earned by the workmen is much diminished by the extraordinary number of ecclesiastical holidays they are required to observe. There are 195 fast days in Greece, and the number of working days in the year never exceeds 265. There are no paupers in Greece, no poor-law or poor rate, and no religious associations for charitable purposes. Beggars are very rare, and absolute destitution may be said not to exist.

Agric-
culture

Agriculture is still in its infancy. A larger proportion of the area is uncultivated than obtains in any country

in Europe except Russia, but that is explained by the unusually large part of it which is occupied by mountous land. We have no exact statistics since 1860, but then only one seventh was under cultivation. Its entire area (exclusive of the Ionian Islands, not then part of it), was 17,409,218 stremas, a stremas being a little over a quarter of an acre. Of these only 17,824,000 were capable of cultivation, and only 6,076,000 actually under it, and half of this amount is always fallow from their system of working it. By universal testimony the country might grow food for three times its present population, yet it has to import cereals every year to an amount exceeding a third of its own produce, and over £1,000,000 in value. But agriculture contends with many difficulties in Greece, most of them, like the various bad soil, the want of roads, and the imperfect agricultural methods, being happily remediable.

The soil is, as a rule, light and thin. In many places there is great lack of sun and running water, but the people are expert in irrigation. The chief products are corn, wine, fruit, and oil. Six different kinds of wheat are grown, producing, in a favourable season, as much as 10 or 13 returns, and after a dry spring from 3 to 5. Good crops are got of rye, barley, and maize, oats do not grow so well, and potatoes not at all. Pulse thrives everywhere, and rice is produced in the plains of Marathon and Argos, and in marshy land elsewhere. Cotton and tobacco have been introduced in our own day, and give good returns.

Greece is still in want of one of the first requisites to agricultural prosperity,—a resident proprietary. The modern kingdom began with almost no proprietors. Under the Turks two-thirds of the land belonged to the sultan and became at the revolution simply national property, which the Government has been selling ever since to private owners on more or less reasonable terms. The peasants are showing a passion for land, and save up to buy their cloths, and in this way a large class of small freeholders is being created, with what effect upon agriculture we have no means as yet of determining. There were 16,122 proprietors in 1861. The relation between landlord and tenant is the misgiving system of taking as rent or usufruct a share of the net produce, usually a third, but in the case of Government land 15 per cent. Great part of the agricultural labourers are not Greek subjects, but are Mahometan Albanians from Thessaly and Epirus, who come into Greece annually in harvest time, in bands of 30 or 40 under a captain, who work at lower rates than Greeks and work longer, for they have no feasts to observe, and who contrive by frugal living to carry back three-fourths of their earnings to their families at home.

The methods of cultivation in use are still primitive. Modern implements are not employed to any great extent, though their manufacture is carried on at Smyrna and the Piræus, and though even the steam plough has been actually introduced in Elis. The Greek plough is still that of Homer, which the husbandman carries about his croft on his shoulder, and which hardly does more than scrape the surface of the ground. It is wrought by oxen, Greek horses—the old Thessalian breed—being small and unfit for farm work. There is no system of rotation of crops. Fields are cropped till they are exhausted, and then left fallow for a year or two. The farmers have no idea of manure or drainage. There are few enclosures, and even the laying out of the fields is slovenly,—a patch of this crop here, and a patch of that there. The houses of the peasantry are sheds of wood or huts of mud, without either chimney or window, but always with a picture of the Virgin inside.

With all the defects in the Greek system of cultivation, agricultural returns show gradual though slow progress. In 1846 the yield for the year of wheat, barley, and maize

was estimated at 6,000,000 kilots, a kilot being nearly 73 gallons, in 1876, 12,000,000. In 1880 there were 2,287,645 steinmas—i. e., 565,048 acres—under cereal crops, which yielded 9,512,993 kilots of grain—i. e. 1,105,807 quaters, or 2 quaters an acre.

Wines vary greatly in numbers, but the wine is poor, with little body and is valued for European use, by the reason put in to preserve it. All provisions are fine, and the best is the wine of Samos, which is shipped largely to Russia. There is still a Malvoisie wine, though it is no longer that which was once so celebrated and it is the name of Malvoisie, and the Kephissia wine of Attica and the red wine of Zante are good products. There has been a large increase in the number of vineyards, and a decided improvement in the quality of the wine made and exported. The vineyards of Greece have been one of the most common and important since 1863. In 1830 there were only 25,000 stammas under vines, there are now 700,000

A grape, peculiar to Greece is that of Corinth, which, from the place where it grows, is called the Corinth. It constitutes the largest export of Greece, and goes almost exclusively to England to make the national sparkling wine. The stem leaves are large and serrated, like those of the grape of France. The vines are well covered with leaves. In 1850 only 10,000,000 vines were raised, and in 1851, after the destruction of the vines by Ibrahim Pasha, only 5,000,000 vines, but in 1851 there were 57,000,000 vines, and in 1876 there were 106,000,000 vines—valued at £1,400,000. There are now 400,000 acres of ground under vines, and the production is probably 100,000,000 vines, in value, and the Corinthian vine is indigenous, and grows only on the northern and western shores of the Morea, on some of the Ionian islands, and at Mytilene, and nowhere else in Greece on the soil in the world. The vines bear in their sixth year, but do not attain the full perfection in the eighth year. The grapes are gathered in the autumn, dried in the sun, and pressed.

The olive and the mulberry are very important products of Italian agriculture. The oil of olive has still its ancient reputation. It is calculated that in Greece in 1876 there were 1,250,000 olive trees, which yielded 9,000,000 olives. In 1885 there were only 2,900,000 trees, yielding 1,000,000 olives. The mulberry grows best in the south of the island, and thus the house of almost every Greek is given up to the raising of silkworms. The silkworms are reared in the houses of the women. There were in 1838 only 800,000 mulberry hedges in Greece, in 1876 there was 2,000,000. A natural predilection of Greece of great importance in viticulture is the fact of the natural growth of vines on the steep slopes of the mountains. In the mountains of Greece there are many vineyards, and the vine is cultivated in all the mountainous places. Vitis is valuable on account of the amount of tannin in its leaves, and is much exported to England and Italy for use in the manufacture of leather. The vine is also cultivated in the plains, which grows largely on Mount Taygetos, beside the insect called kermes, which, when dried, looks like a berry, and is used in dyeing. The leaves of the vine are also used in the manufacture of large quantities of wine. The vine of Greece produces also the grape of the mountain of Taygetos, which is used in the manufacture of wine.

Cotton and tobacco are the only products whose cultivation is free from taxation, the exemption being made with a view to the encouragement of their cultivation. Cotton is now grown to a considerable extent, its culture having received a great impetus during the American civil war. It is produced particularly on the marshy lands of Louisiana, and Flitchers in northern Greece. In 1862 the province was 23,637 quintals, in 1864, 193,615 quintals. The annual yield of tobacco is 4,000,000 oke. Opium, madder, and flax are grown in the northern parts of Greece.

Groves are rich in fruits. The figs of Attica have not degenerated, and they are produced to a considerable extent in other parts also, especially Messenia. In 1884 there were but 50,000 fig trees, in 1861, 300,000. Apricots, oranges, lemons, pomegranates, and citrons grew well in the islands, and the fruit trade might be largely increased.

Though there is much excellent timber in the Greek forests, it is practically useless from want of roads, so that it is hopeless to import wood from abroad. In 1880 there were 7,000,000 stamires of land under forest, and it is estimated that now only 5,500,000 are so

The herds are chiefly held on the mountain pastures, and are mainly sheep and goats. Most of the cattle are used in agricultural work. In 1946 the total number of sheep in the country amounted to 1,260,000, of which 720,000 were in the mountains. Of the 1,000,000 of which 198,292 were work oxen, of horses, 69,787, of mules, 29,587, of asses, 61,001, of swine, 45,776, and of camels, 73. The principal products of the country are wool, hides, and skins. The principal crops are wheat, barley, and buckwheat. The principal industries are the wool and leather industries. The principal exports are wool, hides, and skins. The principal imports are foodstuffs, clothing, and machinery. The principal cities are Thessalonika, Sofia, and Belgrade. The principal languages are Greek, Bulgarian, and Serbian. The principal religions are Greek Orthodoxy, Bulgarian Orthodoxy, and Serbian Orthodoxy. The principal occupations are agriculture, stock raising, and trade.

[illegible]

When Cypriotism assumed the government of Greece fifty years back, he said there were two things he meant to give the nation, - roads and education. The system of education has been very active and has brought about a complete change in the mind of the people. We have no record of statistics on the subject, but Rangabé says that in 1867, more roads had been made than the kingdom was at that time able to maintain. The country had 880 kilometers, and Warsaw, which was then completely unimproved, had only 100 kilometers. It cost more to carry grain from Asia to Athens (25 miles) than to carry it from the Black Sea, which largely relies on the aid of country, not on the coast towns. The country was left almost unimproved because the government had no money. The government had to be forced to be by law obliged to give at least three days' labour in the year, on its equivalent in money, for road making, and a law was passed in 1876 to apply one fifth of the proceeds from the sale of state lands

Manufacturing industries are steadily advancing. According to a Manus report issued in 1878 by Mimosas, director of the statistical bureau factories at Athens, there are in Greece 95 steam mills and factories, with a total of 1087 horse power, the most important of these have been established since 1860. They are: 1) 10 cotton spinning mills, 2) 1 cotton weaving, 2 for cotton spinning, 4 for spinning, 8 for silk weaving, 10 oil mills, 9 for constructing machinery, 4 for making wines and spirits, 3 tanneries, 2 metal foundries, 1 powder mill, 1 distillery and 1 silk rearing establishment. The most important of these workshops The Greeks excel in tailoring, confectionary, and embroidery. As an index to the industrial progress of the nation it may be noted that in the International Exhibition of 1881 there were 157 Greek exhibitors, in 1883, 200, and in 1876, 250. Greece has established a series of industrial exhibitions, the most recent—the new Olympia games, as they are sometimes called, the wealthy Greek lost £2000 a year to found,—which combine athletic, scenic, time and athletic competitions with those of industry, and which have done much to give the Greek people a new sense of the value of the industry is making decided progress. The annual export of raw cotton is diminishing, and its importation is increasing, and, to encourage the trade, there is no duty on native cotton, unless it is sold while the seed is in the cotton; raw cotton was reduced in 1876. Lythra is made chiefly at Smyrna.

The marble quarries of Potosí, Chayta, and Páez are the most important works. The coals of Babos are not much used, as the heat-giving capacity is small. The only mining operations in the country are those of the Laurium Company, which, by help of modern appliances, extracts arsenic from the waste which the ancient workers of the mine threw away. These wastes are thoroughly ground to contain still 130,000 tons of lead. The arsenic or refuse heaps of Laurium are dug up and carried on trucks, by a short line of rail belonging to the company, to the town of Eggenstein, near Cape Colombia, built by themselves to be their workshop and port. There these wastes are melted, and yield annually 19,000 tons of lead, and 300 tons of quantity of silver. There are 3000 operations engaged in this work at Argentina. The value of the export in 1876 was \$150,513.

But the most conspicuous messes of Greece has been in her Commerce, for which the situation and configuration were of the century afford unusual facilities. In 1821 Greece had only 440 vessels, with a total tonnage of 61,450 tons, whereas in 1875 she had 5440 vessels, 27 of them steamers, with a tonnage in all of 262,023 tons, and employing 38,760 men. In 1820 there was hardly a harbour in all Greece with the name, the Piree being then barely accessible to fishing boats, there are now 65 good ports. It had only one lighthouse in 1847, it has now 48, but more are still urgently needed.

The straits of Euboeus have been cleared, deepened, and widened, and an iron bridge thrown across. There are five chambers of commerce. The chief ports are Heracleopolis (Syra), Hydra, Spetzar, Corfu, Zante, Piusus, Patras, Moeelenghi, Nauplia, Santorin, Naxos, Cosmth.

general,—general, including all exports and imports whatever, and special taking in only imports meant for home consumption and exports of commodities produced in the country. The special commerce amounts now to 80 per cent of the general. The general commerce of Greece in 1875 amounted to £26,474,138, of which £5,196,629 were imports and £21,277,509 exports. An idea of the remarkable progress of its commerce may be obtained by comparing these figures with the following:—In 1833 the total Greek commerce amounted to £271,499, and in 1840 to £1,036,471, in 1860 it was £2,147,000, and in 1870 £25,464,000. England occupies the first place among countries trading with Greece, its transactions being more than double those of any other country, and amounting in 1875 to 41 per cent, in 1870 to 48 per cent, of the whole commerce of Greece. Taking the average of the six years ending 1871, Wyndham calculates that 60.75 per cent of the exports of Greece go to England, and that 28.85 per cent of its imports come from England. Turkey and Asia Minor, the nearest neighbours, stand next 25 per cent of its imports are cereals and flour,—the cereals from Russia, Turkey, and Roumania, the flour from France, and 50 per cent are tissues, mainly from England. Though timber is so abundant, it still is one of the largest imports, amounting to £187,778 in 1875. The other chief imports are cattle, salt meat, rice, cereals, butter, iron, and paper. The principal item of exports, amounting to half the value, is cereals, grain in 1875 was £1,250,467, of which £1,083,482 went to England, then come oil, hides, lead, figs, ylang, ylang, and spirits, tobacco, cotton yarn, &c.

The Greek shipping trade is not open to foreigners. The steamers of the Hellenic Company possess a monopoly of the coasts of those waters, the object being to encourage the development of native steam navigation.

There is only one railway in Greece, it is except the private one already mentioned belongs to the Larian Company. It is from Pnyx to Athens, is 73 miles long, belongs to Government, and carries passengers only. Another railway is projected from the Pnyx to Larina (Artemis) in the north (140 miles), with the view of communicating Greece with the general railway system of Europe. There were 1236 miles of telegraph in Greece in 1877, the property of Government, and worked at a considerable loss. The postal system is Government undertakings and has been a source of revenue only since 1861, when postage stamps were introduced. In 1876 there were 151 post-offices in Greece. There are two banks,—the National, with its head office at Athens, and the Ionian, with its head office at Corfu. National bank has 1868 a paid up capital of £540,000, with a reserve fund of £231,000.

The currency of Greece is that of the Latin monetary league, which it joined in 1868, and which allows it to strike 89,000,000 silver francs and a much gold as it thinks proper. Until 1868, Greece had a currency of its own, on the basis of a double standard and the decimal system, the unit being the drachma (equal to 54), which was divided into 100 equal parts called lepta. Coins of various values were struck, but only £4000 in gold pieces, and only £86,000 in silver, an amount quite inadequate for the needs of the country, and quickly disappearing altogether, so that there is probably not a single coin of them now left in Greece. It became necessary therefore to declare the gold and silver coins of other countries a legal tender in Greece, and these, with the notes of the National and Ionian Banks, became, and still remain, the practical currency of the country, and the simplest payments may require a puzzling arithmetical calculation, for people have to pay in sovereigns and thalers prices entered in drachmas and lepta. Though the unit of the Greek currency is the franc, the official accounts of Greece are reckoned in drachmas, in distinction from which the franc is termed the new drachma. There are 36 old and 26 new drachms in the pound sterling.

The system of weights and measures is the Turkish. Their measures of length are—the pique, which is equal to 27 inches, the royal cubit, equal to 1 metre, or 39.37 inches, the stadion, equal to 10.62 English miles. Their measures of superficial extent are—the stremma, equal to one-fourth of an English acre, and the hektar, equal to 10 stremmas. Their standard of weight is the centar of quintal, equal to 128 lb avoirdupois. It is divided into 44 okeas, one oke being equal to 2 64 lb, and subdivided into 400 old and 1280 royal drams. As to the weight of the oke, it is half a centar, or 22 okeas. 816 kilos are equal to 100 quintars.

The financial condition of Greece is unsatisfactory. Its annual finances, expenditure usually exceeds its income, and it is deeply in debt. The new kingdom was born in debt, and contributed to pay the expenses of the revolution that gave it being, and to that original source it has from time to time added fresh liabilities. It has now no longer any credit in the money markets of Europe, and is driven to debt in proportion to the time that any known amount except by loan. The total debt of Greece was £416,460,705, according to Mr. Malesherbes in 1875, and, with the compound interest and the continuation of a fresh debt for every sixteen years during the Sultan's intervention of 1876, it must now be over £1,000,000. The debt consists of two kinds—foreign and home. The foreign debt is of two parts, the first is the original loan, amounting between them to £2,300,000, which were negotiated by the revolutionists in 1821 and 1825 with two English houses at 60 and 65 per cent, and whose coupons are now held mainly by Dutch speculators. On this Greece has never paid a farthing of interest. The Greek treasury, although it accepts the obligation, puts it off from year to year under the heading "Deferred Debt." With accumulating interest at 5 per cent, it had increased to £3,064,500 in 1874. The second part of the foreign debt is a loan of £2,400,000 guaranteed by the three protecting powers on the accession of Otto in 1832, and negotiated with Rothschild & Co. On this Greece paid interest for a few years, but its payment has so fallen into arrear that in 1874 this debt had grown to £2,870,000. There is also a small debt due to the Bavarian Government, amounting now to £250,000, and there are some still smaller debts to other foreign creditors. The internal debt of the country consists partly of indemnity due to sufferers in the War of Independence, partly of loans contracted with capitalists within the kingdom after its credit abroad was gone, it now amounts in all to £5,370,439.

The revenue for 1877, according to the estimate in the budget, was £1,401,887, and the expenditure £1,468,708. The total receipts usually fall short of the budget estimates, for Greece cannot meet her subjects to fill much into arrear with the payment of their taxes, and in 1867 it was calculated there was an aggregate of arrears of taxes amounting to £2,226,000. This revenue is received partly from direct taxes on land and property, partly from indirect taxes, partly from the public services, the post-offices, telegraphs, and printing, partly from the rent of the public domains, mines, quarries, hot springs, salt, fisheries, fairs, olive gardens, vineyards, and other plantations, and partly from the sale of the forests and the ecclesiastical revenues. The largest sources of revenue are the land tax, which brought in 8,500,000 drachmas in 1877, the customs, 23,400,000, and the stamps, 4,000,000. The total cost of collecting the land tax is very extravagant. It takes £28 to collect £100, or ten times more than it does in France. The Greeks are not so very poor. Rangabe estimates that they pay 23 48 drachmas (about 17s.) each in the year as taxes.

Of the expenditure of Greece, nearly one-fourth part goes to pay interest on its debt, another fourth to maintain its army and navy, and a large sum (£188,588) to pay pensions to persons who suffered in the revolution, or who possessed property in the Ionian Islands at the time of their cession. The education and worship of the country cost £75,421, and the foreign office and diplomatic service only £10,257. The administration of justice takes £107,716, and the department of the interior, including the post office and many other outlays, £171,626. The salaries of members of the chambers of deputies come to £16,071.

PART II—GREEK HISTORY

SECTION I.—GREEK HISTORY TO THE DEATH OF
ALEXANDER THE GREAT

The early history of Greece is the first chapter in the political and intellectual life of Europe. In contrast with nations still in the tribal stage the Greeks have already the life of cities, in contrast with the despotic monarchies of the East they recognize the principle that no personal

rule should be unlimited. From the first they appear as a people obedient to reason and to a native instinct of measure. In the political sphere this leads them to aim at a due balance of powers and tendencies in the state, at the definition of duties and the protection of rights. In the intellectual sphere it leads them to explore causes, to interpret thought in clear forms, to find graceful expression.

for the social feelings and sympathies. The historical interest of Greece does not begin therefore only at the point where details and dates become approximately certain, but with the first glimpses of that ordered life out of which the civilization of Europe rose. At a later stage the Greek commonwealths offer the most instructive study which the present world affords in the working of oligarchic and democratic institutions. Then, as the Roman power rises, culminates, and declines, Greek history assumes a new character and a new interest. From Alexander the Great dates the beginning of a modern Greek nation, one, not in blood, but in speech and manner. Two main threads link together the earlier and later history of civilized man. One passes through Rome, and is Latin; the other passes through the new Rome in the east, and is Greek.

In a sketch like the present it would be impossible to attempt a detailed narrative of facts, which, besides, fall to be considered under particular headings. The aim here will be rather to trace in outline the general course of the development, and to indicate, so far as a rapid survey permits, the leading causes and tendencies which were at work in its successive stages.

Six periods may be distinguished. I The prehistoric period, down to the close of the great migrations. II The early history of the leading states, down to about 500 B.C. III The Ionic revolt and the Persian wars, 502-479. IV The period of Athenian supremacy, 478-431. V The Peloponnesian War, 431-404, followed by the period of Spartan and then of Theban ascendancy, 404-363. VI The reigns of Philip and Alexander, 359-323 B.C.

I The Prehistoric Period, down to the close of the great Migrations

"Ancient Hellas," says Aristotle, "is the country about Dodona and the Achæolus, for the Sælon lived there, and the people then called the Chækoi, but now the Hellenes" (*Aristot.*, i, 1). The name *Chækoi* probably meant the "old" or "honourable" folk (Cassius, *Zeyn*, 130). The Italians may have enlarged the application of this name, which they found on the eastern side of the Ionian Gulf. The moderns have followed the Romans in giving it to the whole people who, from very early times, have always called themselves *Hellenes*.

Primitive
Indo-
European
civiliza-
tion

The evidence of language tells something as to the point of civilization which had been reached by the ancestors of the Indo-European nations before the Hellenes parted from the common stock in Central Asia. They had words for "father," "mother," "brother," "sister," "son," "daughter," and also for common affluents by marriage, as "father-in-law," "brother-in-law," "daughter-in-law." They lived in houses, they wore clothes made of wool or skins; as arms they had the sword and the bow, they had flocks and herds, goats and dogs, they dove, if they did not ride, horses; they were a pastoral rather than an agricultural people. They knew how to work gold, silver, and copper; they could count up to a hundred; they reckoned time by the lunar month; they spoke of the sky as the *Uranian-father*. The first great migration from the common home was that which carried the ancestors of the Teutonic, Slavonic, and Lithuanian tribes into north-western Europe. The next was that which carried the ancestors of Greeks, Italians, and Celts into southern and south-western Europe.

Language indicates that there must have been a period during which the forefathers of Greeks and Italians, after the Celts had parted from them, lived together as one people. Again, the Greek language, unique in its characteristic development, tells that the Hellenes, after the Italians had left them, must have long remained an undivided people. But to us this primitive Hellenic unity is prehis-

toric. We first know the Hellenes as a race divided into two great branches, each with well-marked characteristics of its own.—*Dæones*, and *Jæones*, while those who have been less affected by the special causes which produced these divergences from an earlier common type are regarded as forming a third branch, and are called collectively *Æolians*. Further, we hear of a people distinguished indeed from the Hellenes, yet apparently felt (as by Thucydides) to be not wholly alien from them,—a people represented as having been before them in Greece proper, on the coast, and in the islands of the *Ægean*,—the *Pelagians*. In Pausanias some Homeric passages, and those among the oldest, the name *Pelagios* denotes a tribe of Achæon or Æolian Greeks, living in Thessaly (*Paus.*, ii, 681, vi, 235). In other poetical texts of later date, and especially in Herodotus, *Pelagios* is a general designation for people of whom the Greeks knew little definitely, except that they had preceded the Hellenic dwellers in the land. In this second and vague use, "Pelagian" is virtually equivalent to "prehistoric."

The highlands of Phrygia have the best claim to be regarded as the point of departure for the distinctively Hellenic migrations. In these fertile regions of north-western Asia Minor, the Hellenes, after the Italians had left them, may have lived, first as a part of the Phrygian nation, and afterwards as a separate people. From thence first came a great wave of migration westward, and ever speaking the Hellenic speech into Europe, a population which diffused itself through Greece and the Peloponnese, as well as over the coasts and islands of the archipelago. In later ages, when the kinship, though perhaps dimly suspected, was no longer recognized, the Hellenes called these earlier occupants of the land *Pelagians*. It has been conjectured that in *Pelagios* we have combined the roots of *πέλας* and *ἐμ* (*ya*). The name would then mean "the further-goer," "the emigrant." It would thus be appropriate as the name given by the Hellenes, who had remained behind in Phrygia, to the kinsmen who had passed over into Europe before them.

The second epoch of migration from the Phrygian highlands appears to have been one by which single Hellenic speech tribes, with special gifts and qualities, were carried forth to become the quickeners of historic life among most masses of population, among those "Pelagians" who had long been content to follow the calm routine of husbandman or herdsmen. The ancestors of the Ionians went down to the coasts of Asia Minor, and became the founders of a race whose distinctive powers found scope in maritime enterprise and in commerce. The ancestors of the Dorians passed into the highlands of Northern Greece, and there developed the type of hardy mountaineer which united the robust vigour of hunter and warrior with a firm loyalty to ancestral traditions in religion and in civil government.

Of these two branches,—the Ionian and the Dorian,—the Ionian was that which most actively influenced the early development of Greece. But the Ionians themselves shared the first impulses of their progress from a foreign source. Those Carians or "lowlanders" of Syria, whom we call by the Greek name of *Phœnicians*, inhabited the long narrow strip of territory between Lebanon and the sea. Phœnicia, called "Kett" by the Egyptians, had at a remote period contributed Semitic settlers to the Delta of "Isle of Caphtor," and it would appear from the evidence of the Egyptian monuments that the Kefs, or Phœnicians, were a great commercial people as early as the 18th century B.C. Cyprus, visible from the heights of Lebanon, was the first stage of the Phœnician advance into the Western waters, and to the last there was in Cyprus a Semitic element side by side with the Indo-European. From Cyprus the Phœnician navigators proceeded to the southern

coasts of Asia Minor, where Phœnician colonists gradually blended with the natives, until the entire seaboard had become in a great measure subject to Phœnician influences. Thus the Selyni, settled in Lyca, were akin to the Carians, and the Carians, originally kinsmen of the Greeks, were strongly affected by Phœnician contact. It was at Miletus especially that the Ionian Greeks came into commercial intercourse with the Phœnicians. Unlike the dwellers on the southern seaboard of Asia Minor, they showed no tendency to merge their nationality in that of the Syrian strangers. But they learned from them much that concerned the art of navigation, as, for instance, the use of the round-built merchant vessels called *galias*, and probably also a system of weights and measures, as well as the rudiments of some useful arts. The Phœnicians had been first drawn to the coasts of Greece in quest of the purple fish which was found in abundance off the coasts of the Peloponnesus and of Boeotia, other attractions were furnished by the plentiful timber for shipbuilding which the Greek forests supplied, and by veins of silver, iron, and copper ore.

Two periods of Phœnician influence in Europe are distinguished first, a period during which they were brought into intercourse with the Greeks merely by traffic in occasional voyages, secondly, a period of Phœnician trading settlements in the islands or on the coasts of the Greek seas, when their influence became more penetrating and thorough. It was probably early in this second period,—perhaps about the end of the 9th century B.C.—that the Phœnician alphabet became diffused through Greece. This alphabet was itself derived from the alphabet of the Egyptian hieroglyphics, which was brought into Phœnicia by the Phœnician settlers in the Delta. It was imported into Greece, probably, by the Asiatic-Phœnicians of the Gulf of Antioch,—not by the Phœnicians of Tyre and Sidon,—and seems to have superseded, in Asia Minor and the islands, a syllabary of some seventy characters, which continued to be used in Cyprus down to a late time. The direct Phœnician influence on Greece lasted to about 600 B.C. Commerce and navigation were the provinces in which the Phœnician influence, strictly so called, was most felt by the Greeks. In art and science, in everything that concerned the higher culture, the Phœnicians seem to have been little more than carriers from East to West of Egyptian, Assyrian, or Babylonian ideas.

Influence of Asiatic upon European Hellenes

The legends of European Greece speak clearly of foreign elements in civilization and in religious worship which came in from the East. But they do not constrain us to suppose that those who brought in these new elements were always, or as a rule, strangers to the people among whom they brought them. On the contrary the myths constantly say, or imply, that the new comers were akin to the people among whom they came, as the sons of Egyptus are first cousins to the daughters of Danaus, as Cadmus and Pelops, though nominally of foreign origin, are thoroughly national heroes and founders. Hence it appears reasonable to conclude that the East by which European Hellas was most directly and vitally influenced was not the Semitic but the Hellenic East, that the Ionian Greeks of Asia Minor, after having themselves been in intercourse with Phœnicia and Egypt, were the chief agents in diffusing the new ideas among their kinsmen on the western side of the *Ægean*. Asiatic Greeks, who had settled among Egyptians in the Delta, or who had lived among Phœnician colonies in Asia Minor, would soon be confounded, in popular rumour, with Egyptians or Phœnicians. The Asiatic Greeks, as promoters of civilization in European Greece, appear sometimes under the name of Carians,—when they are little more than teachers of certain improvements in the art of war, and have a decidedly foreign character,—sometimes as

Leleges, who are associated especially with Lyca, Miletus, and the Troad, and who, as compared with the "Carians," are the representatives of a more advanced civilization. In the east the name Ionians gave their name to the whole Greek people, as in the Hebrew Scriptures the Greeks are "the sons of Javan,"—the *Umm* of the Egyptians, the *Ionni* of the Persians. It does not appear that the European Greeks of early days used "Ionian" in this way as a collective name for the Asiatic Greeks. But such names as *Javan*, *Jawon*, *Javan* *Avon* point to a sense that the civilization which came from Asia Minor was connected with Ionia. At a later time the Greeks forgot the Ionians and Phœnicians who had brought in Eastern civilization to the western side of the *Ægean*. Vividly impressed by the great antiquity of this civilization itself, especially in Egypt, they preferred to suppose that they had derived it directly from the source.

The appearance of new elements in religious worship is perhaps one great mark of the period during which Greece in Europe was still being changed by influences, Greek or foreign, from the East. The worship which the fathers of the Hellenes had brought with them from the common home in Asia was the worship of the "Heaven-father," the queen father who dwells in ether, whose temple is the sky, and whose altar is most fitly raised on the mountain top, as the ancient shrine of the Achaean Zeus was the grove on the summit of Mount Lycaeus. This is the "Fulgur Zeus, dwelling aloft," to whom the Homeric Achilles prays. But as the united Hellenes were parted into tribes, so to the first simple worship of the Heaven father was added a variety of local cults. And as manna came from other lands began to visit the coasts, they brought in their own gods with them. Thus Melanth, the city god of Tyre, is recognized in Melicetes as worshipped at the isthmus of Corinth. In one Greek form of the worship of Heracles, Asiatism—the goddess of the Phœnician sailors—becomes Aphrodite, who springs from the sea. The myth of Adonis, the worship of the Achaean Demeter, are other examples. These are, again, other divinities who came to European Greece, not directly from the non-Hellenic East, but as deities already at home among the Ionians. Such was Poseidon, and, above all, Apollo, whose coming is everywhere a promise of light and joy.

Little precise knowledge of the earliest kingdoms and the states can be extracted from the legends as they have come down to us, but some general inferences are warranted. The tradition that Minos cleared the archipelago of pirates and established a wide maritime dominion, that he was the first to sacrifice to the Chaites, and that Dedalus wrought for him, may be taken at least as indicating that Crete played a prominent part in the early history of Greek culture, and that there was a time when Cretean kings were strong enough to protect commerce in the *Ægean* waters. Again, though Gordius and Midas have Phrygia passed into the region of fable, there are reasonable grounds for the belief that the ancient kings of Phrygia once exercised dominion over Asia Minor. The Lydians, in Lydia whose origin Semitic and Aryan elements appear to have been mingled, have a twofold interest in this dawn of Hellenic history. First, they represent the earliest kingdom in Asia Minor of which anything is certainly known. Secondly, they are on land what the Phœnicians are on the sea,—carriers or mediators between the Greeks and the East. In the north-west corner of Asia Minor, a branch of the Dardanian whose ancestor is described as worshipping the Pelægian Zeus—founded the kingdom of the Troes, the land of Troy. It has been remarked that the double names of the Trojan heroes,—Alexander, Paris,—Hector, Daunt,—point to the twofold relationship of the Trojans, on the one side to Hellas, on the other to Asia. In

The Myths European Greece we find the race known as the Minyæ, whose early glories are linked with the story of "Jason and the Argonauts," moving southward from the shores of the Gulf of Pagasæ into the valley of Lake Copais, and founding the Boeotian Orchomenus. The early greatness of Thebes is associated with the name of Cadmus, the king priest who introduces the art of writing, who builds the citadel, who founds a system of artificial irrigation. The Achaean princes, whose chivalrous spirit is expressed in the Homeric *Adellus*, rule in the fertile valley of the Thessalian Phthiotis. In the Peloponnese the Pelopidae at Mycœne reign over the Achæans, and Agamemnon is said to rule, not only "all Argos," but "many islands." The principle on which such legends as that of Agamemnon's sovereignty may best be estimated has been well stated by Mr Freeman:—

"The legend of Chulensango, amidst infinite pervasions, receives a certain groundwork of local history, I should expect to find in the legend of Agamemnon, a similar groundwork of real history. There is, of course, the all important difference that we can find the one story, and still we cannot but find the other, by the certain evidence of each upon its documents. This gives us certainty in one case, while we cannot get beyond high probability in the other. Let us Greece history could never lead us to believe that there had been once a single dynasty reigning, if not as sovereigns, at least as vassals, over a large portion of small and petty states in Greece. No local modern history would never lead us to believe that there had once been a petty empire, whose dominions, whose dominions, whose dominions, as the Elder to the Elder. But we know that the Cæsar legend is thus far confirmed by history, there is, therefore, no a priori objection to the analogies of the Pelopid legend. The truth is that the idea of such an extensive dominion would not have occurred to a later monarch, unless some real history or tradition had suggested it to him. So, again, without some such groundwork of history or tradition, no one would have believed upon Mykênæ, a place actually unimportant in later history, at the capital of the Mycæne empire. The romance here transferred the capital of Kérî from Achaia to Pîræ, had it really been Pîræ, no one would have believed that the idea of such an extensive dominion would not have occurred to a later monarch, unless some real history or tradition had suggested it to him."

Tradition of migration in Greece proper We now come to a phase in the development of early Greece which tradition represents as following, but at no great interval, the age in which a Pelopid dynasty ruled at Mycæne and fought against Troy. This is the period of great displacements of population within the mainland of European Greece. The first of these migrations is that of the people afterwards known as Thessalians. A fierce tribe of mounted warriors, they passed from Thesprotia in Epirus over the range of Pindus, and subdued or drove out an Æolic population who dwell about Aîné, in the fertile lowlands of southern Thessaly. Those of the Æolians who had not submitted to the conquerors passed southward into the land thenceforth called Boeotia, where, between Orchomenus and Thebes, they founded a new home. Their conquest of Boeotia appears to have been difficult and gradual, and even after the fall of Orchomenus and Thebes, Platæa is said to have maintained its independence. The legend placed these events about 1194 B.C., or sixty years after the fall of Troy. About twenty years later in the mythical chronology occurs the third and more famous migration, known as the return of the Heracleidæ. We need not enter here into the details of the myth. It will be enough to indicate the results to which an examination of the legend leads. The Dorians, migrating southward from the highlands of Macedonia, had established themselves at the northern foot of Parosus, in the fertile district between that range and Cithæra, which was thenceforth called Doris. In the course of time these Dorians conquered the Peloponnese, the Dorians were associated with other tribes. Among these were the Hyllæans, who were believed to be of Achæan origin, and who traced their descent from

¹ "The Mykæne and Boeotian Elements in Early English History," *Revue*, 1st series, p. 29

the hero Hyllus, son of the Thyrinthus Heracles. The Hyllæan chiefs of the expedition represented themselves, accordingly, as seeking to reconquer that royal dominion of Heracles in the Peloponnese of which his descendants had been wrongfully deprived by Eurystheus. Hence the Dorian migration itself came to be called the "Return of the Heracleidæ." The migration had two main results:—(1) turn of the Dorians, under leaders claiming Heracleid descent, overthrew the Achæan dynasties in the Peloponnese, and either expelled or subjugated the Achæan folk; (2) a portion of the Achæans, retreating northward before the Dorian invaders in the south, drove the Ionians on the coast of the Corinthian Gulf out of the strip of territory which was thenceforth called Achæia, and these Ionians sought refuge with their kinsfolk in Attica. It is in the nature of the heroic myths to represent changes of this kind, which may have been the gradual work of generations, as effected by sudden blows. Some comparative mythologists have maintained with much ingenuity that the "Return of the Heracleidæ" is merely one of those alternations which balance each other in the hundred forms of the solar myth. It appears more consistent with reason to believe that there was really a great southward movement of population, which resulted in the substitution of Dorian for Achæan ascendancy in the Peloponnese. We cannot pretend to fix either the exact time at which the movement or the period which was required for its completion. One thing may, however, be affirmed with probability. It cannot have been done all at once, as the myth says that it was. The displacement of the Achæans was accomplished only by degrees, and perhaps after the lapse of centuries.

The same remark applies to those three streams of Dorian migration from European Greece to the coasts of Asia Minor, which are represented as having ensued on the Dorian conquest of the Peloponnese, and which may naturally be connected with the disturbance of populations proper to which the southward advance of the Dorians caused. The Achæans, driven from their old seats in the south, moved northwards, and, reinforced by Æolic kinsmen from Boeotia and Thessaly, established themselves on the north-west coast of Asia Minor, where Lesbos and Cyme became their strongholds. By degrees their dominion spread inland, until they had become masters of Mysia and the Troad. The Æolic migration which thus created an Asiatic Æolis was unquestionably the slow work of generations. The immediate cause of the Ionic migration, 2. The which began later than the Æolic, appears to have been the overcrowding of Attica by the Ionians driven out of Achæia. The Æolic settlements had been the work of a people migrating in large masses. The Ionic colonization seems to have been effected rather by smaller numbers of adventurous settlers, sprung from the noble Ionian families of Attica and the Peloponnese, who claimed to rule over the Ionic communities already established on the Asiatic coast. The Dorian colonists, following the southward direction of their previous conquests, settled on the south-west coast of Asia Minor. The islands of Cos and Rhodes received Dorian settlers, and, after what was probably a long struggle, the Dorianes subdued Crete.

While the populations had thus been settling down into the places which they were to occupy during the historical age of Greece, a movement had been in progress on the European mainland which tended to quicken among the various tribes a sense of the unity of the race. This was the establishment of local associations among neighbouring tribes for the common worship of the same god. These associations were of a federal character, and while the members of the association were independent in their matters, they were subject to a common central authority in all that concerned religious worship. Such a federal

association was called an *amphiktyony*, that is, a *league of neighbors*. The most important of such leagues was the Delphic amphiktyony, of which the object was to conserve the worship of Apollo at Delphi. This league arose in Thessaly, where the conquerors who had come in from Epirus sought to establish themselves more firmly by embracing the cult of Apollo. It was afterwards extended through the southern districts until it included most of the tribes dwelling about Cetea and Parnassus. The members of the Delphic amphiktyony gave a new meaning and value to the federal compact by applying it to enforce certain obligations of humanity in war. They took an oath that they would not use each other's towns, nor, during a siege, cut off the supply of water. It was in connection with the Delphic amphiktyony that the name *Hellene* appears to have been first distinctly recognized as the national name. The earliest collective name of the race, in Greek tradition, had been *Graikos*. The members of the Delphic amphiktyony chose as their federal name that of *Hellene*,—a name of sacred associations, if we may connect it with that of the *Selloi* or *Selloi*, the priests of the Pelagian Zeus at Dodona,—in the region which, according to Aristotle, was the most ancient Hellas. The circumstances which gave currency to *Hellene* as a common appellation have left a reminiscence in the myth that Hellen was nearly related to Amphiktyon.

The Homeric poems may be regarded by the student of history as a picture of national and social life, illustrating the whole variety of Greek experience down to the close of that age which saw the tides of Eolie, Ionic, and Dorian migration flow from the west to the east of the Aegean. It is a distinct question how far recoverable his torical fact is embedded in their text, or how far trustworthy inferences may be drawn from them in regard to a supposed series of events. But at least the legends of the Achaean princes and warriors are there, as they came through Eolie minstrels to the poets of Ionia, and, various as may be the ages and sources of the interwoven materials, the total result may be taken as a portraiture, true in its main lines, of the age from which these legends had come down. In the political life described by the Homeric poems the king rules by divine and hereditary right. But he is not, like an Eastern monarch, even practically despotism, he is bound, first, by *themistes*, the traditional customs of his people, next, he must consult the *boile*, the council of nobles and elders, and, lastly, his proposals require to be ratified by the *agora*, or popular assembly. The social life is the counterpart of this. It is a patriarchal life, in which the head of the family stands by his dependents in a relation like that of the king to his subjects. It is, within the family pale, eminently humane, and the absence of a chaunt which should include all mankind is in some measure compensated by the principle and practice of hospitality. The position of free-born women is high,—higher than in the historical ages, and polygamy is unknown among Greeks. Many of the pictures of manners, especially in the *Odyssey*, have the refinement of a noble simplicity in thought and feeling, and of a genuine courtesy which is peculiarly Hellenic. The useful arts are still in an early stage. The use of the principal metals is known, but not, apparently, the art of smelting or soldering them. Money is not mentioned, even being the usual measure of value, and there is no certain allusion to the art of writing.

II The Early History of the leading States down to about 500 B.C.

In the history of the Peloponnesus after the Dorian migration we begin to be on firmer ground. There may still be large room for doubt as to particular dates or names, but the ages left permanent records in the institu-

tions which survived it. The first thing which should be borne in mind with regard to the Dorian migration is that its direct influence was confined to three districts of the Peloponnesus, Argolis, Laconia, and Messenia, while the thoroughly Doranized Of the other three districts, Achaia remained almost wholly unaffected, Elis and Achaia were affected only indirectly, through the influx of the populations which the Dorians had displaced. The first rank in the Peloponnesus was long retained by Argos. The ancient primacy of its Achaean princes was inherited by its Dorian rulers, and now, under the dynasty of the Temenides, Argos acquired a new prestige as the head of a federative Dorian heptapolis, of which the other members were Phlius, Sicyon, Troezen, Epidaurus, and Corinth. It was only by slow degrees that the power arose which was destined to eclipse Argos. When the Dorians entered the Sparta valley of Eurotas, they found "hollow Laedæmon" already shared among people of other tribes. Lelages, Minyans, and Achaean had been there before them. Both Eolian and Achaean elements remained in the land. The settlement of the Dorians was made in a strong position under Mount Taygetos, on the right or western bank of the Eurotas, and the fact that, unlike most Greek cities, it was not founded on a rocky base, but on arable soil, was expressed by the name *Spata* (sown land). It was indeed less a city than a group of rude hamlets,—the camp of a military occupation. And, as a natural stronghold, defended by an alert garrison, it dispersed with walls Sparta was at first only one member of a Laconian heptapolis. It was at a later stage that Sparta became the head-town of the country, and the seat of a central government. The origin of the dual kingship may probably be traced to this period. Such a dualism has no parallel elsewhere among Dorians, and, as regards one at least of the two royal lines, we know that the Agiade Cleomenes proclaimed himself an Achaean. The two royal lines of the Agiade and Eurypontides may have taken their beginning from a coalition or compromise between Dorian and Achaean houses. Afterwards, when it was deemed to explain the dualism and to refer both lines to a common source, Agis and Eurypont were represented as descended from the twin sons of Aristodemus, Eurysthenes and Procles.

The spread of Spartan power in the Peloponnesus was preceded by the building up of that political and social system which made the Spartan citizens a compact aristocracy, exclusively devoted to the exercises of war. The personality of Lycurgus is shadowy. He has even been Lycurgus, classed with those beings who, like Prometheus, Hermes, and Phoebos, bestow on men that gift of fire without which they could not have attained to a high civilization. But the charge of excessive credulity can scarcely be brought against those who hold, with E. Curtius, that "there really lived and worked in the first half of the 9th century B.C. a legislator of the name of Lycurgus, a man who, as a born Heraclid, was called to take part in public affairs." It is another question whether he was the author of all the institutions which were afterwards ascribed to him. The example of another legislator who stands in a far clearer light of history,—the Athenian Solon,—whom the orators sometimes credit with the work of Cleisthenes in addition to his own, may serve to show how loose such ascriptions often were. But at least the work of Lycurgus may be assumed to have marked an epoch in the history of the Spartan system. This system rested, first, on a distinction of three orders. Dorians, the pure Spartans, and those of Sparta, as opposed to mere Laedæmonians, and to them belonged all political power. Lycurgus, said the tradition, assigned nine thousand lots of land to as many Spartans, the land descended from father to eldest son, and, failing issue, reverted to the state. The older or non-

The Sparta system

Dorian population, settled chiefly on the mountain slopes around the Spartan lands, were called *Perioeci*. They were free farmers, who had no share in the government, and were not required to perform military service. Lastly, the *Hilots* cultivated the land, of the Spartans, not as slaves, belonging to private masters, but as serfs of the commonwealth, hence no Spartan citizen could sell a *Hilot* or remove him from the land. From each farm the *Hilot*, had to produce annually a certain quantity of barley, oil, and wine, if there was a surplus, they could keep it for themselves. This condition of the *Hilots* was thus in some respects better than that of ordinary Greek slaves.

Character of the government

But it was such a convenience to remind them that they had once been a free peasantry. It was, thus, as much for their sake as for the sake of the state, which made it so peculiarly galling. The hatred of the *Hilots* was a standing menace to the Spartan commonwealth. As Aristotle says, the Spartan kingship meant practically a life tenure of the chief military command. The government was essentially an official oligarchy, in which the power of the irresponsible *ephors* was not importantly modified by the gerousia, while the popular assembly played a part hardly more active than that of the *Homeric* agora, with its formal privilege of simple suggestion or veto. The military training, from childhood upwards, to which the whole social life of Sparta was made subservient, was at first a necessity, but it soon became thoroughly identified with the ambition and with the pride of an exclusive warrior caste. Sparta was simply marked off from the other Greek communities by this systematic treatment of war as the business of life. When the military prestige of Sparta began to decline in the course of the 4th century B.C., it was remarked that this was due to the increased attention which other states had begun to pay to the art of war, whereas in old days the Spartans had been like professional soldiers matched against civilians.

Ground of the Spartan law

The mountain wall of Taygetus had set a barrier between Laconia and Messenia, which might have seemed to forbid the extension of Spartan power towards the west. If the Dorians in Messenia had fully preserved the warlike character of the race, they would probably have had little to fear. But they seem to have been in some measure enervated by the material wealth of a country which, at the same time, excited the envy of their neighbours. Myths have grown thickly around the story of the two Messenian wars. This, at least, appears certain: the gradual conquest of Messenia by Sparta occupied not less than a hundred years (about 750-650 B.C.). The legend that, at a crucial time, the stirring war songs of the Atrid Tyrtæus raised the sinking spirit of Sparta, agrees with the tradition of a long and doubtful struggle. Messenia was twice confined to the two chief combatants. Messenia was aided by other Peloponnesian states which dreaded a like fate for themselves,—Argos, Sicyon, Arcadia. Sparta was helped by Elis and Corinth. When Messenia had been conquered and the Dorian inhabitants reduced to the state of *Hilots*, Sparta had overcome the most difficult obstacle to her ambition. By conquests, of which the details are obscure, she won from Argolis a strip of territory on the eastern coast of the Peloponnese, and finally carried her north eastern border to Thyrea. In southern Arcadia alone the Spartan arms were decisively repulsed by Tegeæ, and the Tegeans, accepting the supremacy of Sparta, were enrolled, about 560 B.C., as honoured allies of the power which they had checked.

The Olympic festival

The republic warned Sparta that it was better to aim at leading the Peloponnese than at conquering it, and an opportunity was found of asserting this leadership in a manner far more effective than any military demonstration. At Olympia, in the valley through which the Alpheus

passes to the western coast, there was an ancient sanctuary of the Pelægian Zeus. An amphitryony, or league of neighbouring towns, held sacrifices and games there once in four years, the management of the festival being shared between Pisa and Elis. A dispute arose between these two states. Sparta confirmed Elis in the religious superintendence of the festival, and at the same time arrogated to herself the political headship of the sacred league. Every effort was now made by the Spartans to extend the popularity and enhance the brilliancy of the Olympic games. Sparta—already supreme in Laconia and Messenia, already the victorious rival of Argos in the east of the land—now appears at the Olympian shrine of Zeus in a character peculiarly well adapted to attract the loyalty of the western Achæans. The general recognition of Sparta as the first state in the Peloponnese may be said to date from the time when, under Spartan auspices, the Olympic festival acquired a new celebrity.

For political reasons Dorian Sparta had always cherished the traditions of the Achæan princes, but the monarchy of the Achæan age, if it still existed anywhere, was a rare survival. The form of government which had generally succeeded to it was oligarchy, that is, the rule of a group of noble families claiming descent from the heroes, possessing certain religious rites in which no aliens participated, and claiming to be, by a divine authority, the interpreters of the unwritten law. These families made up the state. The commons, who lived in or around the city as artisans, labourers, or farmers, were free men, but had no political rights. The Dorian ascendancy in the Peloponnese was peculiarly favourable to oligarchies. Sparta was, in fact, such an oligarchy, though not of the closest kind,—the Dorian citizens being the privileged class, while the *Perioeci* answered to the commons elsewhere. It was a fortunate circumstance for the political development of Greece that oligarchy did not, as a rule, pass directly into democracy. A period of transition was needed, during which the people, hitherto deprived from all chance of political education, should learn the meaning of membership in the state.

This was afforded, at least in some measure, by that peculiar phase in the life of the Greek commonwealths, known as the tyranny, which intervenes between oligarchy and democracy,—the age of the tyrants. A tyrant meant one whose power is both superior and contrary to the laws. An absolute ruler is not a tyrant, if the constitution of the state gives him absolute power, nor is a ruler unauthorized by the laws a tyrant, because he rules mildly. The genesis of the tyrant was different in different cases. Most often he is a member of the privileged class, who comes forward as the champion of the people against his peers, or throws the oligarchy with the help of the people, and establishes his own rule in its stead. Such was Cypselus at Athens. Sometimes he is himself one of the people, as was the case with Orthagoras, who (about 675 B.C.) overthrew the Dorian oligarchy at Sicyon. The case of Cypselus at Corinth is intermediate between these two, for he belonged to a noble Dorian house, though not to the inner circle of those Bacchiads whose rule he overthrew. Or the tyrant is one who raises himself to absolute power from the stepping stone of some office with which the oligarchy itself had entrusted him. An example is supplied by Peisistratus at Athens, and by the tyrants of some Ionic cities in Asia Minor. Lastly, the tyrant might be a king who had overstepped his constitutional prerogative. Peisistratus, king of Athens, is adduced by Aristotle as an instance of this rarer case. In all cases the tyrant properly so-called must be distinguished from a ruler whom a community has voluntarily placed above the law, either temporarily or for his life. Such was properly called an

tyranny from monarchy to this

The
results

monarchs of detraction,—as Pittacus of Mitylene. The benefits conferred on the Greek commonwealths by the tyrannies were chiefly of two kinds. (1) The tyrant often instituted new religious festivals, in which the whole body of the citizens might take part. A feeling of civic unity was thus created, which could not exist while the nobles formed a separate caste, as exclusive in their worship as in their other privileges. (2) The court of the tyrant became a centre to which poets and artists were attracted. Such a man as Pericles of Cimnith (635-585) might aim at resembling an Eastern despot, but his encouragement of liberal arts must still have given an impulse to the higher civilization of Cimnith. Polycrates of Samos, the friend of Anaxagoras, welcomed all men of fine gifts to his court. Protagoras showed a like taste for poetry; and for the artistic embellishment of Athens. The root of evil in the tyranny was its unlawful origin, and its consequent reliance upon force, frequently leading the tyrant to aim at keeping the citizens in a state of helplessness and mutual distrust. But the founder of a tyranny was usually a man with some innate qualities for command, and the baser forms of oppression were not required until he had given place to a weaker successor.

Coloniza-
tion

The age of the oligarchies and tyrannies coincides with the most active period of Greek colonization, which is covered an impulse both from redundant population and from political troubles at home. The two centuries from 750 to 550 B.C. saw most of the Greek colonies founded. Sicily received settlements from both the two great branches of the Greek race. Naxos, founded by the Chalcidians of Erebus (735 B.C.), with Leontium and Catana, founded soon afterwards by Naxos, formed a group of Ionic communities on the eastern side of the island. Syracuse, founded by Cimnith (734 B.C.), Gela, colonized by Rhodians and Cretans (690 B.C.), and Agrigentum, of which Gela was the parent city (583 B.C.), were among the chief of the Dorian commonwealths on the south eastern and south-western coasts. Those Sicilian cities formed a fringe round the Sicel and Sicant of the interior, but, though in the presence of non-Hellenic populations, they never lost among themselves the sharp distinction between Dorian and Ionian (or "Chalcidian"), a distinction which was long the key-note to the inner history of the Siciliots. The earliest of the Greek settlements in Italy was the Ionic Cumæ, on the coast near Cape Misenum, a little to the north-west of Naples. It was founded by Chalcidians of Erebus, as early, according to the tradition, as 1050 B.C. The Dorians Tarentum,—a colony of Sparta,—and the Achæan (Æolie) settlements of Sybaris and Croton, dated from the latter part of the 8th century B.C. Posidonia (Paestum) was founded by Sybaris. Locri, an Æolie settlement near Cape Zephyrium (whence its epithet "Epizephyriana"), and the Ionic Rhegium, founded from Chios, complete the series of flourishing cities which made south-western Italy appear as a new and richer land of the Hellenes, as Megale Hellas, *Magna Græcia*. The turning-point in its prosperity was the war between the two foremost of the Achæan cities, ending in the destruction of Sybaris by Croton (510 B.C.). By this event, just at the time when the Ionians of Asia Minor were passing under the sway of Persia, the Greeks of Italy were rendered less able to make head against the native tribes of the peninsula. The name Megale Hellas remained, but its old significance was gone, the spirit of confident progress had been quenched.

Italy

The distinctive character of Greek colonization is seen less vividly when, as in Sicily and Italy, Greek communities clustered together, than at those lonely outposts of Hellenic life where a single city stood in barbarian lands. Mascula (Massilia) was founded by the Ionians of Phocæa about 600 B.C., and became the parent of colonies on the

Sprawled
with
men

east coast of Spain. If Carthage had not fulfilled the purpose for which it was founded, by serving as the jealous guardian of Phœnician commerce in the western Mediterranean, Greek settlements would probably have multiplied on those shores as rapidly as elsewhere. Cyrene, on the African coast, was a Dorian colony (610 B.C.) from Thuri, itself colonized by Sparta, and became the founder of Barca. Cocyra was colonized by Cimnith about 700 B.C., and joined with the mother-city in founding settlements (among others, Epeidamnus) on the coast of Epirus. The northern shores of the Ægean and the Propontis were dotted with colonies, from the group of towns planted by Chalcids in the peninsula thence called Chalcidicæ, to Byzantium,—which, like Selymbria, was founded by Megara (657 B.C.). Among the colonies on the western coast of Asia Minor, Miletus was especially active in creating other settlements, particularly for purposes of commerce. Neaurata, in the delta of the Nile, was a trading colony from Miletus, and flourished from 550 B.C. On the southern shore of the Propontis and the Buxine, Cyricus and Sinope (itself the parent city of Trapezus) were daughters of Miletus. Here too were the remotest of Greek settlements,—Panticapæum (Kerch in the Crimea), afterwards the capital of the Greek kings of the Bosporus, Olbia (or Borythene) on the adjacent mainland, and Istria, at the mouth of the Danube. The above enumeration, though not exhaustive, will serve to mark the wide extent of the area included by Greek colonization. As the city was the highest unit in the political conception of the Greeks, so the Greek colony contained within itself the essentials of a complete political life. Its relation to the parent-city was one of filial piety, not of constitutional dependence. In so far as the cult of the gods and heroes whom it worshipped was localized in the mother-country, it was needful that a link should exist between the religious rites of the colony and those of its parent, and this religious continuity was symbolized by the sacred fire which the founder (*ekkyrtes*) carried with him from the public hearth to the new settlement. For the rest, Massala and Olbia were cities of Hellas in as full sense as Athens or Sparta. It was due to the self-sufficing character (*autarkia*) of the Hellenic city as such that Hellas was not a geographical expression

When Attica first comes into the view of history, it already forms a single state of which Athens is the capital. The kingly period is over, and, though a close oligarchy still exists, there are signs of coming change. But the hints of poetical legend, and sometimes the sure evidence of the ground itself, enable us to go further back, and to form at least a general conception of earlier chapters in the story of the land. Of these plans on the northern shore of the Saronic gulf,—those of Megara, Eleusis, and Athens,—the Attic plan is that which offered the greatest advantage to settlers. It is the most spacious, it is the best watered, it holds the most central position in the district which stretches south-east from the chains of Cithæron and Paros to the Ægean, it has the best seaboard for navigation and commerce, and it contains the best site for a city. Traces of early immigrants of various stocks survived in the names of places, in worship, and in legends. Eleusis, Pireus, Phaleron, and Minyan names, the myths and cults tell also of Carians, Leleges, Cretans, Thyrenians. But the chief influence which came to Attica from beyond sea must have been that of the Phœnician settlement at Salamis (Salamis, the place of peace), a name which, as in the Cyprian worship of Zeus Salaminus (Zeus Salamin), points to the Phœnician effort to establish friendly intercourse between alien races. Herodotus (viii. 44) distinguishes four periods in the early history of Attica, with each of which he connects an appellation. In the first the inhabitants were "Polioi," called "Kraones," in the

town of Attica

second "Kekropide" in the third "Athenian," in the fourth "Ionian." The extensive series of rock dwellings found on the south and west of the Acropolis are, by the ingenious and probable conjecture of E. Curtius, connected with the first of those periods. This primitive Pelagic settlement was the Rock town (*psarai*), its inhabitants were Kresnoi, the dwellers in the rocks. The second period was one in which the Acropolis became the seat of a small number of nobles, and of a princely family claiming descent from the earth-born Cecrops. The citadel becomes the centre of religious and political life, beneath it dwell Pelagic bondmen, who work for the Cecropide as the Cyclopee worked for the Peisandri at Argos. The city of the Cecropide—no longer of the Kresnoi—becomes the head of the twelve cities among which the Attic land was divided. As the leading families are drawn towards the Cecropid city, rivalries ensue, which are mythically interpreted by the strife of rival gods on the Acropolis. Zeus, the Pelagic god, has priority of possession. But his honours are disputed by Poseidon, the deity of the Thracians settled on the gulf of Salamis, and of their priestly clan, the Eumolpide. The third claimant is Athena, the divinity of a race possessing a higher culture, the giver of the olive to the land. The final victory falls to Athena. But Zeus keeps the place of honour as protector of the whole community,—Poseidon, and Athena share his sanctuary with Poseidon. The mythical Erechtheus,—representing at once the ancient Poseidon and the nursing of Athena,—is the symbol of the victory and the consolidation. This is the third period of Herodotus, "Erechtheus having succeeded to power," the Cecropide become Athenians. The fourth and last period is that in which Ionian settlers press forward from their earlier seat on the bay of Marathon, and establish themselves—not without opposition—on the banks of the Ilissus. The worship of the Ionian Apollo takes its place beside that of Zeus and Athena. The Ionic settlement on the Ilissus was included in an enlarged Athens, and the close of the epoch was marked by that union (*synoikeia*) of Attica into a single state which Attic tradition ascribed to the hero king Theseus.

The light soil of Attica had protected it from such wholesale changes of population as had passed over Thessaly, Boeotia, and the Peloponnese. In contrast with the occupants of those lands the Attic population claimed to be indigenous, and the claim was true in this sense that the basis of the population was an element which had been there from prehistoric times. On the other hand the maritime advantages of Attica had been sufficient to attract foreign immigrants. Thus in Attica no one type of life and character prevailed to the same extent as the Dorian in the Peloponnese or the Aeolian in Boeotia. The Ionian element was tempered by others older than itself. This fact is the key to that equable and harmonious development which so remarkably distinguished the Attic people alike in culture and in politics. The institutions which are found existing in Athens in the 7th century B.C. may be regarded as dating from the age which tradition called that of Theseus,—the age, namely, in which the loose canton system of Attica was knit together into a single state. The inhabitants of Attica form three classes,—the Eupatrides or nobles, the Geomori, free husbandmen, and the Demurgi, or handicraftsmen. The government was wholly in the hands of the Eupatrides, who alone were citizens in the proper sense. The Eupatrid order was divided into four tribes, called after the sons of Ion—Ceklon, Ioplios, Egekoron, Argadeis. Each tribe contained three *phylai*, *tribes*, or clans, and each clan three *gens* or houses. The members of each clan were united by the worship of an heroic ancestor, and all the clans were bound together by the common worship of Zeus Herkeios and Apollo Patrons.

tion

Clives

The transition from monarchy to oligarchy was more gradual in Athens than it seems to have been elsewhere. First, the priestly office of the king was taken away, and, as the old name *basileus* implied religious as well as civil authority, he was henceforth called simply the ruler, *archon*. But the office of archon was still held for life, and was hereditary. The second step was to appoint the archon for ten years only. The third and last step was to divide the old royal power among nine archons appointed annually (683 B.C.). The first archon, called Eponymos, because his name marked the date of official documents, had a general supervision of affairs, and in particular represented the state as the guardian of orphans and minors, the second archon was high priest (*basileus*), the third was commander-in-chief (*polemarch*), the remaining six were the custodians of the laws ("thesmothetai"). After this reform, two events are the chief landmarks of Attic history before Solon. The first is the legislation of Draco, the second is the revolution of Cylon. Hitherto the Eupatrides had been the depositaries and sole interpreters of an unwritten law. Draco, himself a Eupatrid, was now com- missioned, not to frame a new code, but to write down the laws as they existed in oral tradition. To a later age the law of Draco became a proverb of severity, but then severity was that of the rude age from which they had come down, not of the man who was employed to tabulate them. By this code (620 B.C.), and by the establishment of a court of fifty-one judges (*hetai*) in capital cases, the people were so far secured against abuse of the judicial office. But the existence of serious popular discontent a few years later is shown by the attempt of Cylon (612 B.C.). Stimulated by the example of his father-in-law, Theagenes, the tyrant of Megara, he resolved to seize the supreme power at Athens. Promises of relief and of a new agrarian law gained him adherents among the distressed classes, but when he had succeeded in seizing the Acropolis, he found himself disappointed of popular support and surrounded by the troops of the archons. He escaped. His patrons surrendered, on the promise of the archon Megacles that their lives should be spared, but when they had left the altars, they were cut down. The "Cylonian crime" was denounced by the people as having brought a pollution upon the city, and the punishment of the whole clan of the Alcmæonidae—to which Megacles belonged—was demanded as an expiation. The Eupatrides refused to yield, until Solon, one of their order, prevailed on the Alcmæonidae to stand a trial before three hundred of their peers. They were found guilty of sacrilege, and were banished.

Solon was now to come forward as the umpire of still graver issues. The influence of his ardent and lofty nature on the people is expressed in the legend that his recitation of his elegy, "Salamas," freed them to strike the blow by which "the fair sleep" was won back from the Megarians. The part which he had taken in the Alcmæonid affair was well fitted to make him trusted both by the nobles and by the people. His legislation had a twofold scope. In the first place he aimed at giving immediate relief to a class whose plight was desperate. As there was little money in the land, those in whose hands it was had been able to force up the rate of interest as they pleased. The small farmers (geomoni) were being crushed out of existence by a load of debt, mortgaging their farms to their creditors, who, in default of land, could even sell the debtor as a slave. Solon depreciated the value of the silver drachma by 27 per cent, so that a debt of 100 old drachmas could be paid with 73, and the state was cancelled altogether. In a fine lambic fragment, Solon calls his witnesses of his work "the greatest of Olympian deities, the black earth, wherefrom I took up of yore the pillars that had been set in many a place,"—these (*poia*) being the stones

that marked a mortgaged homestead. Secondly, Solon named at establishing a permanent equilibrium between classes. He classed the citizens by their rated property as (1) Pentakosio mohimnoi, (2) Hippeis, (3) Zeugitai, (4) Thetes. The first class alone could hold the archonship, the fourth had no political privilege except that of voting in the assembly. But Solon made the assembly (*ekklesia*) what it had never before been, a real power. He gave to it (1) the right of passing laws, (2) the right of calling magistrates to account, (3) the right of electing archons. At the same time he created a council of four hundred, to be elected annually by the people, through which all business should be introduced to the assembly. He strengthened the old Eupatrid Aseopagus, by adding to its jurisdiction in homicide a general power of moral censorship, and provided that the archons of each year should, if found worthy, pass at the end of it into this senate. Athenians of a later age often described Solon as the founder of the democracy. This was not his own conception of his work. We have his own description of it—

"I gave the people as much strength as is enough, without taking away from them due share (*timē*), or adding thereto. But as for those who had power and the splendour of riches, to them I gave no counsel, even that they should not uphold violence. And I stood with my strong shield spread over both, and suffered neither to prevail by wrong." Solon was not a champion of popular rights, but a philosophic mediator between classes.

The removal of the urgent pressure of usury, the substitution of wealth for birth as the canon of privilege, and the bestowal of strictly limited political power on the people were Solon's achievements. It is no proof of their inadequacy that they were soon followed by the appearance of a successful demagogue. The Attic population was locally divided into three classes,—the *Diacri* or the "highlanders" of the north-east district (the poorest), the *Parali*, the boatmen and fishermen of the coast, and the *Pedieus*, the richer farmers of the Attic plain. Each of these classes formed a political faction, with an ambitious noble at its head. The *Diacri* were led by Pisistratus, the *Parali* by Megacles, the *Pedieus* by Lycurgus. On the pretence that he had been murderously assaulted by the enemies of the people, Pisistratus obtained a guard of 60 men. He was presently increased to 400. He then seized the Acropolis (560 B.C.). After having been twice driven out by the combined forces of the *Parali* and the *Shore*, he finally established himself as tyrant in 545 B.C., and reigned till his death in 527 B.C. He did not abolish Solon's constitution, though he received some of the highest offices for members of his own house. His government appears to have been mild and wise. He set the example of submission to the laws. By many new enactments he promoted good order and morality. The convenience of the citizens and the beauty of Athens were consulted by the construction of new buildings, roads, and aqueducts. There were but two things to remind Athenians that their paternal rule had been founded in force,—the presence of armed troops, and the levy of taxes on private lands. Pisistratus was succeeded by his eldest son Hippasus. In 514 B.C. Hipparchus, the brother of Hippasus, was murdered by Harmodius and Aristogiton, in revenge for an affront offered to the sister of Harmodius. The rule of Hippasus, which had hitherto resembled that of his father, now became cruel. The Alcmeonidae—who had been in banishment since the final return of Pisistratus in 545—had won the favour of the Delphic priesthood by an act of libelality. The temple at Delphi having been burned down, they had undertaken to rebuild it, and, instead of common limestone, which would have satisfied the contract, used Parian marble for the east side of the temple. They now exerted their influence.

Whenever Sparta or a Spartan consulted the oracle, the response always included a command to set Athens free. At last Cleomenes, king of Sparta, took the field. The children of Hippasus fell into his hands, and, to save them, Hippasus voluntarily withdrew from Athens (510 B.C.). The rule of the Pisistratid house was now at an end. In the Pisistratid phase of the song which gave it merited glory to Ilium, Cleomenes and Aristogiton, Athens was once more under equal laws.

But there was a vehement strife of factions. The Eupatrid party, under Isagoras, wished to restore the aristocracy of pre-Solonian days. The party of popular rights was supported by the Alcmeonidae, and led by Cleisthenes, whose father, Megacles, had married the daughter of Cleisthenes, tyrant of Sicyon. Cleisthenes, in the words of Herodotus, took the people into partnership, and by Cleisthenes' reforms he instituted ten new tribes, which included all the free inhabitants of Attica. Each tribe was composed of several *demes* (townships) not adjacent to each other, thus securing that the old clans should be thoroughly broken up among the new tribes. The number of the Council (*Boule*) was raised from 400 to 500,—50 members being elected from each of the ten new tribes. Further, it was arranged that each tribal contingent of 50 should take it in turn to act as a committee (*prytanis*) of the council,—a board of presidents (*epistates*), and the chairman of the day, being again chosen in rotation from the committee. A new office was also instituted. The command of the army was given to a board of ten Generals (*strategoi*), one being elected by each of the tribes. In later times the strategy became ministers of foreign affairs. Jury courts of citizens were organized out of the assembly, to share the administration of justice, which had hitherto belonged to the courts of the archons and the Aseopagus. As a safeguard for the state against party struggles, it was provided that, if the Council and the Ecclesia should declare the commonwealth to be in danger, each citizen might be summoned to indicate by ballot the name of any man whom he thought dangerous, and that, if the same name was written on 6000 tickets (*ostraka*), the man so indicated should go into exile for ten years, without, however, losing his civic rights or his property. This was the institution of *ostracism*. Finally, choice by lot was substituted for voting in the election to the archonship, thus diminishing the danger of factious partisanship.

Isagoras, the leader of the party opposed to these reforms, had a zealous ally in Cleomenes, king of Sparta. Cleisthenes, they alleged, was aiming at a tyranny such as that of his grandfather and namesake at Sicyon. Sparta, the leading Doran state, was in a manner the recognized champion of aristocracy against revolution. The Spartan herald summoned the Athenians to banish the accused Alcmeonidae, and Cleisthenes voluntarily left Attica. Cleomenes arrived at Athens with his army. Isagoras was made archon, seven hundred "democratic" families were banished, the newly constituted Council of five hundred was dissolved. But now the people rose in arms. Cleomenes and Isagoras were besieged on the Acropolis. On the third day of the siege they surrendered. Cleomenes and his troops were allowed to withdraw. Isagoras escaped, but his Athenian adherents were put to death. Cleisthenes now returned to Athens. He seems, however, to have excited popular indignation by promoting a treaty with Persia, by which the supremacy of the Persian king was acknowledged. He thus left colour to the accusation of his enemies that he was aiming at a tyranny, and he was banished. Cleomenes presently invaded Attica a second time, with the Peloponnesian allies. But the other Spartan

king, Demetrius, was opposed to his designs. The Corinthians refused to follow him, and his army broke up when it had advanced no further than Eleusis. Meanwhile the Thebans and the Chalcidians of Euboea had been induced to take up arms against Athens. Freed from the danger of the Peloponnesian invasion, the Athenians marched against the Thebans. They found them on the shore of the Euripus, and routed them. Crossing the strait into Euboea, they defeated the Chalcidians on the same day. The lands of the Chalcidian knights (Hippolotæ) were divided in equal lots among four thousand Athenians, who occupied them, not as colonists forming a new city, but as non-resident citizens of Athens. This was the first *Leontineus*. The Spartans, incited by Cleomenes, now made a final effort to impair the democratic strength of Athens. Hippus was invited from his retreat on the Hellespont to Lacedæmon, and a Peloponnesian congress was convened at Sparta to discuss a project for restoring him to Athens as tyrant. The representative of Corinth urged that it would be shameful if Sparta, the enemy of tyrannies, should help to set up a new one. The congress was of his mind. The scheme failed, and Hippus went back to Sigeum.

In these five years (810-800) which followed the fall of the Peloponnesian empire, the future of Athens was decided. Athens had become a free commonwealth, in which class grievances no longer hindered the citizens from acting together with vigorous spirit. The results were soon to appear in work done by the Athenians, not for Athens only, but for all Greece.

The time was now drawing near when Greece was to sustain its first historical conflict with the barbarian world. There was not, in the modern sense, an Hellenic nation. But there were common elements of religion, manners, and culture, which together constituted an Hellenic civilization, and were the basis of a common Hellenic character. The Greeks of Egeus, united in the worship of the Pelægian Zeus, had become the Hellenes of Thessaly, united in the worship of Apollo. The shrine of Delphi, at first the centre of the most important amphictyony, had now become the religious centre of all Hellas. It was acknowledged as such by foreigners, by the kings of Phrygia and Lydia in the east, by the Etruscan Tarquins in the west, as afterwards by the Roman republic. In political matters also Delphi was a common centre for the Greek states, mediating or advising in feuds between cities, and giving the final sanction to constitutional changes. A sense of Hellenic unity was further promoted by the great festivals. It has already been seen how Sparta lent new brilliancy to the gatherings at Olympia. The Pythian festival was revived with a fresh impulse after the first Sacred War (695-686), in which Cleisthenes, tyrant of Sicyon, and his allies destroyed Cræus, the foe of Delphi. A little later two other festivals were established, the Isthmian and the Nemean, at about the time when the tyranny of the Cypselids was overthrown at Corinth, and that of the Cithægæids at Sicyon. The games of Nemea and of the Isthmus were new assertions of the Dorian sentiment which was so strongly opposed to tyrannies, and they exemplify the manner in which such festivals were fitted to express and strengthen national sympathy. In the gradual growth, too, of Hellenic art,—with a stamp of its own distinct from that of Assyria, Babylonia, Phœnicia, or Egypt,—the Greeks found a bond of union, and the temples were centres at which the growth of such an art was encouraged and recorded. Above all, the Iomeric poetry, in which the legends of the heroic age took a form that appealed to every branch of the Greek race, was a witness to the contrast between Greek and barbarian. It was the interpretation of this contrast which made Homer so peculiarly the national poet. Still the unity of Greece had hitherto been

little more than an ideal. The only great enterprise in which Greeks had made common cause against barbarians belonged to legend. The first historical event in which the unity of Greece found active expression was the struggle with Persia.

III. *The Ionian Revolt and the Persian Wars, 502-479 B.C.*

The twelve Ionian cities on the western coast of Asia Minor formed a community which kept itself thoroughly distinct from the Æolian colonists to the north and the Dorians to the south. The Pan-Ionic festivals preserved the memory of the common descent. The Ionian life and culture had a character of its own. But the Ionian cities had no political cohesion, nor had they any recognized Ionian leader. One after another they became tributary to the kings of Lydia. The process of subjugation commenced at the time when the Lydian dynasty of the Mermnads (about 716 B.C.) began to make themselves independent of Assyria. It was completed by Croesus, to whom, about 550 B.C., all the Ionian cities had become subject. Croesus was friendly to the Greeks; he respected their religion, Lydia, and enriched its shrines; he welcomed distinguished Greeks to Sardis. All that was exacted from the Ionians by Croesus was that they should acknowledge him as their suzerain, and pay a fixed tribute. The Persians, under Cyrus, defeated Croesus and conquered Lydia about 547 B.C. The whole coast-line of Asia Minor was afterwards induced by Harpagus, the general of Cyrus. The Persians, under Croesus, destroyed the Greek temples. But in Persia was not till the reign of Darius, who succeeded Cambyses in 521 B.C., that the Ionians felt the whole weight of the Persian yoke. Darius, the able organizer of the Persian empire, preferred that each Ionian city should be ruled by one man whom he could trust. He therefore gave system also support to tyrannies.

It is characteristic of the political condition of Ionia that the revolt was not a popular movement, but was the work of two men, each of whom had private ends to serve. Hippias, tyrant of Miletus, had rendered a vital service to Darius during his Scythian expedition (513 B.C.) by disbanding the other Greek leaders from breaking down the bridge over the Danube, which secured the retreat of the Persian army. Having been rewarded with a principality in Thrace, he justly became suspected of ambitious designs. Darius sent for him to Susa, and detained him there on the pretext that he could not live without his friend. Meanwhile Aristagoras, the son-in-law of Hippias, ruled at Miletus. In 502 Aristagoras undertook to restore the exiled oligarchs of Naxos, and for this purpose obtained 200 Persian ships from Artaphernes, the satrap of western Asia Minor. The enterprise miscarried. Aristagoras, drawing the anger of Artaphernes, now began to meditate revolt. He was encouraged by secret messages from Hippias, who hoped to escape from Susa by being sent to suppress the rising. Aristagoras laid down his tyranny, and called on the people of Miletus to throw off the Persian yoke. The other Ionian cities followed the example. They deposed their tyrants and declared themselves free. The Æolian and Dorian settlements made common cause with them. Cyprus also joined in the revolt (500 B.C.). Aristagoras next sought aid beyond the Ægean. Sparta held aloof, but five ships were sent by the Æolians, and twenty by the Æthians. The united Greek force surprised Sardis, and set fire to it, but was presently driven back to the coast. The Athenians then went home. Darius was deeply incensed by this outrage. The whole Persian force was brought to bear on Ionia, and Miletus was invested by land and sea. In a sea fight off Lade, an island near Miletus, the Ionians were decisively defeated by a Persian fleet of nearly twice their number,

partly through the shameful desertion of the Samians and Eretrians during the battle (496 B.C.). The Persians soon afterwards took Miletus by storm (495 B.C.). The Greek cities of the Asiatic seaboard and of the Thracian Chersonese successively fell before them.

But the vengeance of Darius was not yet complete. He could not forget that the Greeks from beyond the sea had helped to humiliate him, and he resolved that the punishment of Athens and Eretria should be as signal as that of his own vassals in Ionia. A Persian army, under Mardonius, crossed the Hellespont and advanced through Thrace. But the Persian fleet which accompanied it was shattered by a storm in rounding Mount Athos. The progress of Mardonius was also checked by the Thracians, and he retreated to Asia.

The ambition of Mardonius had been to bring all European Hellas under the rule of the Achæmenides. The second Persian expedition, guided by more cautious counsel, had a narrower scope. It was directed strictly against those states which the great king had vowed to punish. The intrigues of the Persiastates were busy in promoting it, and Hippias was to lend his personal guidance to its leader. But before the new forces set out Persian agents were sent through Greece to demand the symbols of submission from the cities. Most of the islands feared to refuse. Ægina, now a prosperous maritime power, complied from another motive than fear. Great Persia was welcome to be as an ally against Athens. The Athenians called upon Sparta, whom they thus recognized as the head of Greece, to punish this treason to the Hellenic cause, and Cleomenes, after overcoming the opposition of his royal colleague, Demaratus, took an avenging revenge on the Æginetans by depositing ten men of their chief families in the hands of the Athenians.

In 490 B.C. the second Persian expedition crossed the Ægean under the command of Datis and Artabanes. Naxos was sacked, Eretria was betrayed. It seemed hardly doubtful that Athens too must fall. The Persians landed in the bay of Marathon, enclosed by the spurs of Buleon (Pentelicon) and the hills of the Diacra. They thus avoided the dangers of a voyage round a rocky coast, and no part of Attica, Hippas told them, was so favourable to cavalry. The Athenians had sent for help to Sparta, but a religious scruple forbade the Spartans to march before the time of the full moon. Nine thousand Athenian citizens, with the slaves who carried their shields, went forth to meet the Persians at Marathon. On the way they were joined by a thousand Plataeans,—the whole force of that city,—who came to stand by their old protectors. Miltiades, formerly the ruler of the Cheloniæ, was one of the ten Athenian generals. Five of these voted for awaiting Spartan help. The other five, led by Miltiades, were for giving battle at once, and the vote of the polemarch, Callimachus, turned the scale in their favour. The Greeks charged down from the hills upon the Persians. The Greek centre was driven in, but the Greek wings prevailed, and then closed upon the Persian centre. The Persians fled to their ships. Six thousand Persians fell. The Greek loss was about 192. Believing that traitors at Athens had signalled to the Persians to surprise the city while undefended, the army hastened back. The Persian fleet soon approached, but seeing troops on the shore, sailed away for Asia.

After the victory of Marathon Miltiades was all-powerful at Athens. He asked the people to give him a fleet, in order that he might strike another blow at Persia while the effects of Marathon were fresh. His demand was granted. But he employed the fleet in an attempt to wreak a private grudge on the island of Paros. At the end of twenty-six days he returned to Athens baffled, and suffering from a wound in the thigh. He was indicted for

having deceived the people, and was sentenced to a fine of about £12,000. Being unable to pay it, he was disfranchised as a public debtor. His wound mortified, and he died, leaving debt and dishonour to his son Cimon. Aristides was now the most influential man at Athens, as Themistocles was the ablest. Themistocles foresaw that the Persians would return, and that Athens could resist them only on the sea. He aimed therefore at creating a new Athenian navy. Already (491 B.C.) he had persuaded the Athenians to set about fortifying the peninsula of the Piræus, which, with its three harbours commanded by the height of Munychia, offered greater advantages than the open roadstead of Phalerum. He now urged that the revenues from the silver mines of Laurium should be applied to building a fleet. The frequent hostilities between Athens and Ægina enforced the advice. Before 480 B.C. Athens had acquired 200 triremes. Aristides was at the head of a party who viewed this movement with alarm. Had not the naval empire of Miletus, Chios, and Samos been transient? The land-holding citizens who had fought at Marathon would give place to a mob of sailors and traders. An unstable democracy would carry the state out of the ancient ways. The strife of parties came to an issue. An ostracism was held and Aristides was banished,—probably in 481 or 483 B.C. Themistocles remained the leader of Athens in the new path which he himself had opened. Athens was now the first maritime power of Greece.

The repulse at Marathon had probably not prevented the Persian commanders from concentrating their expedition as in a great measure successful. Darius resolved on the complete subjugation of Greece. But, when vast preparations had been in progress for three years, he died, leaving the throne to Xerxes, the eldest of his four sons by Atossa, the daughter of Cyrus (485 B.C.). Xerxes was not, like Xerxes his father, a born ruler or a trained warrior. But he was profoundly convinced that all human beings were the natural slaves of the Persian king, and he was influenced by a strong war-party in the palace, with Atossa and Mardonius at its head. The house of Persimatus, the ambitious Alcanda of Thessaly, and Demaratus, the exiled king of Sparta, united in urging an invasion of Greece. It was in vain that Artabanes, the uncle of the king, argued on behalf of the moderate party at the court. Orders were given to raise such an armament as the world had never seen, a host which should display the whole resources of the empire from the Indus to the Ægean, from the Danube to the Nile. Forty-six nations were represented by the forces which wintered at Sadis in 481 B.C. A fleet of 1200 triremes, and about 8000 transports and smaller craft, assembled near Cyrene and Phœnix on the Ionian coast. In the spring of 480 B.C. Xerxes led about a million of men to the Hellespont, whither the fleet went before to meet them.

Greece was probably never stronger than it was at this time. The population of the Peloponnese may have been about two millions. Athens, according to Herodotus, had 30,000 citizens. The Boeotian towns and the islands were prosperous. The proportion of slaves to freemen varied from perhaps four to one at Athens to as much as ten to one at Corinth or Ægina. Life was still simple and vigorous. Society was not divided into rich classes enervated by luxury and poor classes enfeebled by want. The public palaestrae were schools of physical training for war. But that which Greece lacked was political unity. Aristocracy and democracy were already rival forces. Everywhere the aristocrats felt that a victory over Persia must have a national character, and must so far be a victory for the people. They inclined therefore to the Persian cause, and the stand in defence of Greece was

eventually made by a few states only. Sparta, as the leading city of Greece, took the first step towards the formation of a national party, by convening a congress at the isthmus of Corinth in the autumn of 381. Here Themistocles showed his statesmanship by prevailing on the Athenians to abstain from disputing the hegemony of Sparta. Most of the Peloponnesian cities were represented at the congress. But Argos and Achaia, jealous of Sparta, held aloof. In Boeotia, Thebes,—the enemy of Athens,—favoured Persia. In Thessaly the dynasty of the Alaeidae were the active allies of the invader. Gelon of Syracuse refused to aid unless he were to lead. The Corinthians promised sixty ships, but did not send them. Crete also failed to help. The states which fought against Persia were thus few,—Sparta with her Peloponnesian allies, Athens, Ægina, Megara, Platæa, Thebes. This national league expressed indeed the principle of Greek unity, but Greece was far from being united. The "mediating" party was strong, and it counted some adherents in many even of the patriotic cities. Whichever democracy had enemies Persia had friends.

Plan of
defence

The first idea of the national defence was to arrest the torrent of invasion at some northern point which could be held against great numerical odds. Tempe proving untenable, it was resolved to make a stand at Thermopylæ. When Leonidas had fallen with his 300 Spartans and the 700 Thebans who shared their heroic death, the next object of the Peloponnesian allies was to guard the isthmus of Corinth. The peculiar misfortune of Athens in the war was her position between two gates, the first of which had been forced by the enemy. The Greek leaders seem to have assumed at first that it was vain to oppose the Persian land forces in an open field. Xerxes occupied Athens, and the flames which destroyed its houses and temples at last avenged the burning of Sardis. The Greek ships, which had gained some advantage over the Persian fleet at Artemisium in the northern waters of the Euboean strait, had moved to Salamis as soon as it was known that the Persians had passed Thermopylæ. The homeless population of Athens had been conveyed to Salamis, Ægina, and Troezen before the arrival of Xerxes. And now the first cast of Themistocles was verified. Athens, and Greece itself, were saved chiefly by the Athenian ships,—200 in number out of a total of 366. The Peloponnesian leaders wished to withdraw the fleet to the isthmus. Themistocles saw that if he left Salamis it would disperse. He sent word to Xerxes that the Greeks meditated escape. The Persian fleet surrounded them in the night. Next day the

Attack

Battle of
Salamis

battle of Salamis was fought. Of 1000 Persian ships, 300 were destroyed, the rest fled. It was on the same day that Gelon of Syracuse defeated the Carthaginians at Himera in Sicily (480 B.C.). Xerxes lost heart and retreated to Asia, leaving Mardonius with 300,000 men to finish the war. In the summer of 479 Athens was again occupied and destroyed by the Persians. Now at length Sparta came to the rescue. Pausanias, the guardian of the young son of Leonidas, led 110,000 of the allies into Boeotia, and utterly defeated the army of Mardonius near Platæa (479 B.C.). On the same day the troops of the Greek fleet defeated those of the Persian fleet in a battle on the shore at Mycale near Miletus. This victory set Ionia free from Persia.

League
of the
Persian
war

The Persian war had revealed both the weakness and the strength of Greece. The legendary autonomy of Thessaly had shown that they were eager to establish the supremacy of their house with the help of Asiatic despotism. Such states as Argos and Thebes had not been ashamed to indulge jealousy and party spirit by betrayal of the common cause. Even Sparta and the Peloponnesian allies had been disposed to confine their endeavours to the defence of

their own peninsula, leaving Athens and the northern cities to their fate. On the other hand the struggle had brought into strong relief the contrast between absolute monarchy and constitutional freedom. This appeared in two things: the Greek strategy was superior, and the Greek troops fought better. Athens, in particular, had shown how both the intelligence and the spirit of citizens are raised by equal laws. The mistakes of the invaders,—which, to a Greek mind, might well have seemed the work of Ate,—were such as are natural when a vast force is directed by the intemperance of a single will. Artamenes and Demaratus advised Xerxes to occupy Cythera. The Thebans advised Mardonius to sow dissension among the Greeks by means of bribes. Both counsels were judicious, and both were neglected. Time is, in war, the surest ally of superior numbers and resources, but the impatience of the Persian commanders staked everything on a few pitched battles. Again, the Persians, unlike the Lydians of old, destroyed the Greek temples. They thus conferred an immense moral advantage on their antagonists. He could no longer doubt that he was helped by his gods.

IV The Period of Athenian Supremacy, 478-404 B.C.

In the space from the Persian to the Peloponnesian War the central interest belongs to Athens. The growth of Athenian empire, the successive phases through which it passed, and its influence on the rest of Greece, the inner development of Athenian life, political, intellectual, social,—these are the salient features in a period of about fifty years. The first cast of Themistocles after the repulse of the Persian invasion was to restore the fortifications of Athens. The jealous interference of Sparta, instigated by Ægina and Corinth, was defeated by his ingenuity. A wall of larger extent than the old one was built round Athens, and a strong wall was also carried round the Piræus. The Persians had been driven out of Ionia, but they still held many places on the Thracian and Asiatic coast. The Spartan Pausanias, commanding the Persian Greek fleet, took Byzantium from the Persians in 478 B.C. He now formed the design of making himself a despot, and by adoption of the manners of a Persian grandee became so offensive to the Greek captains that they requested the Athenian commanders to assume the leadership of the fleet. Pausanias was recalled to Sparta, and his successor found that the hegemony had already changed hands. The league, of which Athens now became the head (477 B.C.), was intended to continue the national defence against Persia. Its special purpose was to guard the Ægean. Aristides was chosen to assess the rate of contribution for the members. The representatives of the several cities met at the temple of Apollo in Delos, where the common fund was also deposited. Hence the league was called the Confederacy of Delos. It was only gradually that this league of confederacy, with Athens for a president, passed into an Athenian empire over tributary cities. At first each city contributed ships to the common fleet. But the practice arose of allowing some cities to contribute money instead of ships. A city which did this had no control over Athens, and no protection against attack. One after another of the discontented allies revolted from Athens, changed, and was forcibly reduced to the condition of a subject. The earliest example (466 B.C.), Thasos was the next (465 B.C.), and as early as 449 B.C. only three smaller allies remained free,—Samos, Lesbos, and Chios. The transfer of the common fund from Delos to Athens (about 459 B.C.) was merely the outward sign of a change in which most members of the original league had already been compelled to acquiesce. In the earlier years of the Confederacy the work for which it had been formed was not neglected. Of the successes gained against Persia the

Gravitate
in its
character

most notable was the victory of Cimon over the Persians, both by land and by sea, at the mouth of Euxine (466 B.C.). But, as Athens assumed more and more distinctly an imperial character, the common fund came to be regarded as a tribute which could be applied to exclusively Athenian objects. This was the grievance which made the very name of the "tribute" (*phoros*) so hateful.

Culmination of Athenian power

The years 457-445 B.C. may be taken as marking the greatest extension of the Athenian empire. It was in 457 that their victory at Cnephosia in Boeotia, following on their defeat at Tanagra, enabled the Athenians to break up for a time the oligarchical league over which Thebes presided. Democracies were established in the Boeotian towns, and Athens was virtually supreme, not only in Boeotia, but also in Phocis and Locris. In 455, after a struggle of some years, Athens conquered Egina. But now the tide began to turn. In 453 the defeat of the Athenians at Coroneia destroyed the power of Athens in Boeotia, Phocis, and Locris. Oligarchies were restored. First Eretria and then Megara revolted from Athens. The Spartans, released from a truce of five years (452-447), invaded Attica. They advanced, however, no further than the Thracian plain, and it was believed that their leader, the king Pleistoneas, had taken Athenian bribes. Freed from this danger, Pericles was enabled to reduce Eretria. But the dream of an Athenian land-empire was over. In 445 a truce for thirty years was concluded between Athens and Sparta. Athens was left with dependencies on the mainland of Greece. Henceforth the Athenian empire was to be maritime only.

Thirty Years' Truce

Between the conclusion of the Thirty Years' Truce and the events which led to the Peloponnesian War the most important incidents were—first, the revolt of Samos and its reduction by Athens (440 B.C.), next, the foundation by Athens of two settlements, Thurii, on the site of Sybaris in southern Italy, and Amphipolis, on the Strymon, in Thracian.

Constitutional changes at Athens

Meanwhile the inner political life of Athens had passed through great changes. Soon after the Persian war, the fourth or poorest class of the Solonian timocracy had been made eligible to the archonship. This was done on the proposal of Aristides himself. The maritime population of the Piræus was now large, and it had become impossible to exclude the main body of the citizens from the chief offices of the state. The development of Athenian democracy had been secured by that loyal unity of civic action and feeling which the Persian war had produced. Themistocles, whose policy had been the source of those new impulses, did not remain to direct them; he was accused of complicity in the Persian intrigues of Pausanias, and ostracized (about 471 B.C.). Aristides died in 468. Cimon, the son of Miltiades, was now at the head of a conservative party. The other party, which was rather progressive than properly democratic, was led by Pericles, an Alcmaeonid, and Ephialtes. A blow was dealt to the influence of Cimon and his party when the Spartans insultingly dismissed an Athenian force which had marched, under Cimon, to help them in reducing the insurgent Helots on Mount Ithome (464 B.C.). Soon afterwards some important reforms were proposed and carried by Ephialtes. The powers of the Areopagus were diminished. Probably it lost its general censorial power and its veto upon legislation, retaining its jurisdiction in homicide. The archons and generals were deprived of their discretionary judicial powers. Henceforth the people was to be the final judge both in criminal and in civil causes. The jurors chosen from the Helææ were now organized as a permanent system of courts, every juror receiving a fee from the state for each day of his attendance. Cimon was ostracized, and the exasperation of the conservative party was shown by the

assassination of Ephialtes (457 B.C.). Cimon was succeeded in the leadership by his kinsman Thucydides, son of Melesias, and when, in 413 B.C., Thucydides also was ostracized, there was no longer any dissident resistance to the policy of Pericles. Athens was now strengthened and embellished by a series of public works. Already in 457-456 two long walls had been built, one from Athens west to Phalerum, the other from Athens to the Piræus, and about 415 a third or intermediate wall, parallel to the latter, was built on the proposal of Pericles. The Odeon, a theatre for musical performances, arose on the east side of the theatre of Dionysus, under the Acropolis. On the Acropolis itself the Erechtheion, the shrine of Athens Polias, which had been burned by the Persians, was rebuilt on a greater scale, and the Parthenon, the magnificent temple of the Virgin Athene, containing the chryselephantine statue of the goddess by Phidias, was constructed under his superintendence from the plans of Ictinus and Callicrates (438 B.C.). The Propylææ or portals, forming a colonnaded entrance to the Acropolis on the western side, were completed a few years later.

The period known as "the age of Pericles" may be roughly defined as the years, from 460 to 430 B.C. The idea which pervades the whole work of Pericles is that the Athenian people, having been called upon by circumstances to rule over a wide alliance, must be trained to rule worthily. Pericles was opposed to attending the empire of Athens, but he was induced to hold it, because he saw the danger of giving it up. And, in order that it should be held wisely, he saw that the people must be educated, first, politically, by constitutional freedom, and next, intellectually and socially, by general cultivation. The *theoricon*, or money given to the citizen to pay for his seat at the theatre, was doubtless a party expedient, like the pay provided for the juror and for the citizen-soldier, it belonged to a plan for breaking the exclusive power of wealth. But it also fitted into the system by which Pericles sought to bring the citizens collectively under the influence of art in all its noblest forms. Painting, music, sculpture, architecture, had each its place in this scheme, but for the statesman's object no single instrument was perhaps so potent as the drama. It was a time of outstanding forces, in which one chief peril was lest the generation to which a larger future was opening should lose its hold on what was best in the past. The religious tradition and the new ethical subtlety were nowhere reconciled in so lofty an ideal as by Sophocles; nor could any presentment of art rival the theatre in its power of quickening a sympathetic enthusiasm.

The "age of Pericles" would have produced better results for the political future of Athens if Pericles himself had been less great. As Thucydides says, the nominal democracy was virtually the rule of one man. The informal sovereignty of Pericles hindered the use of those who might otherwise have been trained to succeed him. During his lifetime the need of a restraining force was not felt in the reformed institutions, for that force was supplied by a single mind. But when he was gone it was seen that the new equilibrium of the state depended on a Pericles being at its head. Probably Pericles himself believed that there were men who could continue what he had begun, and if he was wrong, that cannot detract from the glory of what he did for his own time.

V. *The Peloponnesian War, 431-404 B.C. The Period of Spartan and then of Theban Ascendancy, 404-362 B.C.*

In examining the causes which led to the breach of the Thirty Years' Truce, and to the Peloponnesian War which followed it, Thucydides distinguishes two alleged or immediate causes from a third cause which was not alleged,

Peloponnesian War

but which lay deeper than either of the others. The two allied cities were—(1) the active help given by Athens to the Corinthians in their struggle with Corinth concerning Epidaurus, a colony of Corinth; (2) the Athenian blockade of Potidaea, a Corinthian colony which had revolted from Athens. The most central issue was the growth of Athenian power, and the alarm which this caused to the Lacedaemonians. In truth the aim of Epistemonus and the aim of Potidaea were merely the sparks which happened to kindle the flame. This long conflict which we call the Peloponnesian War had been prepared from the time when the Athenian democracy, founded by Cleisthenes, had become a power in Greece through the successful struggle against Persia. From that time there were two antagonistic principles, represented by two rival cities—originally by Sparta, democracy by Athens. The other cities grouped themselves naturally round these. All Greece was divided between these two ideas. The Peloponnesian War, the collision between them. It would be inconsistent with the limits and the scope of this sketch to enumerate the details of the war in each of its twenty-seven years. Let us most aim at indicating the periods into which it falls, the leading characteristics and tendencies which it presents.

First period of the war, 431-421 B.C.

1. The first period of the Peloponnesian War comprises the years from its commencement in 431 B.C. to the peace of Nicias in 421, hence sometimes called the Ten Years' War. As one of its main features was the frequent invasion of Athens by the Peloponnesians, the latter called it the Attic War. The result of it was that Sparta had gained nothing, and that Athens had lost nothing except Amphipolis. By the peace of Nicias Athens kept all places which had surrendered voluntarily. Those allies of Sparta from which these places had been taken were naturally discontented. Corinth and Thebes especially were aggrieved. In spite of all the mistakes of Athens,—in spite of the devastating plague,—in spite of such reverses as the defeats at Delium and Amphipolis, and the loss of the Chalcidic towns,—Athens remained on the whole triumphant, and against what Brasidas had done for Sparta might be set the victories of Pheidon and the capture of Sphacteria. On the other hand the peace of Nicias had brought dissatisfaction into the Spartan confederacy.

Second period, 421-413 B.C.

2. The second period of the war extends from the peace of Nicias in 421 to the catastrophe of the Sicilian expedition in 413. The four years immediately following the peace of Nicias are the only years during which the great fundamental antagonism on which the whole war rested was temporarily obscured. Many of the allies of Sparta were discontented, and the intrigues of Alcibiades were active among them. But it was in vain that oligarchic allies were gained for the moment to the democratic cause. The normal relations were soon restored. Then came the Athenian expedition to Sicily, ending in a crushing disaster. Thucydides thinks that the mistake lay, not so much in an original miscalculation of strength, as in the failure at Athens to support the expedition after it had gone. It is indeed possible that with other guidance Athens might have conquered Syracuse. But at least it was essential that Athens should put forth its whole strength, if only for the reason that no people resembled the Athenians so closely as the Syracusans. Yet never had the Athenians fought under greater disadvantages. The Athenian force was in attack, at Syracuse they had to act on the defensive. The bold and versatile Alcibiades was made a public enemy. Nicias, timid and in weak health, is opposed to Gylippus, who unites a Doric energy of hatred to Athens with something like Ionian command of resource. And, when everything had been lost except

a chance of saving the army, the perversity of Nicias defeated the prudence of Demosthenes. The Sicilian disaster was the turning-point of the war. Pericles had warned the Athenians against needless ventures and a policy of aggrandizement. They had incurred a needless risk of tremendous magnitude, and had lost. If they had won, Alcibiades would probably have raised a tyranny on the ruins of then democracy.

3. The third and last period of the war is from the third Sicilian defeat in 413 to the taking of Athens by Lysander in 404, a few months after the battle of Egospotami. This is the period called the Decelean War, because Decelea in Athens was occupied by the Spartans in 413, and continued to be a permanent base for their operations against Athens. As the sea-bond of Asia Minor was the centre of much of the fighting, it is sometimes also called the Ionian War. In this last chapter the war takes a new character. After the Sicilian overthrow Athens was really doomed. The Decelean War is a prolonged agony of Athenian despair. Athens had now no hope but in her ships, and the leaders had to find their own supplies. The Spartan treasury was also empty. This want of money on both sides gave the mastery of the situation to Persia. And it was due to the factious treason of Alcibiades that the aid of Persia was given to Sparta. Athens was ultimately conquered, not by the Spartan confederacy, but by the oligarchy of Athens bent on winning political opponents. The "Revolution of the Four Hundred," with its brief success, greatly contributed to the exhaustion of the city. Even at Egospotami, even when Lysander was before Athens, it was the baneful influence of Athenian faction that turned the scale. When Athens had been taken and the walls destroyed, Sparta was once more the first power in Greece. When Thrasybulus and the patriotic exiles had overthrown the rule of the Thirty Tyrants, they restored the Athenian democracy, but they could not restore the old Athenian power.

Sparta itself was changed. The old Spartan institutions, altered had taught a simple reliance on disciplined strength. In the Peloponnesian War Sparta had won the victory with Persian gold. Already the love of money had found its way into the state which had once been so carefully protected from it. Differences of degree had arisen between the citizens, whose equality had been the very basis of the old Spartan life. Citizens who had been impoverished by the use of pikes, and who could no longer pay their share of the public tables, were now distinguished as "integers" (*trochiloi*) from those who retained their full civic rights (*hectoi*). Spartan commanders abroad were not always inaccessible to bribes. The habit of military discipline indeed remained. Spartans were still distinguished, as a rule, by gallantry in the field, by care for the dead, and by attention to the ritual of the gods. Nor had the valley of the Eurotas remained closed to the higher culture of Greece. The old type of Spartan leader—the tough soldier incapable of eloquence or of finesse—had ceased to be the only type. An Athenian might have envied the powers of persuasion and the diplomatic tact of such Spartans as Brasidas, Lysander, or Gylippus. But the qualities of the old Sparta were seldom fused into a perfect harmony with the new accomplishments. Such men as Laches and Callistratus were rare. The balance of political power, as it existed in the old constitution, had also been unsettled. The kings were still, as of old, the commanders-in-chief on land. But the new office of the admiral (*navarchos*) was invested with the chief command at sea. The supreme control of the state had passed more and more into the hands of the ephors, and the ephors, chosen annually, were not always incontestable.

Sparta had waged the Peloponnesian War in the name

of freedom. The Greek cities were to be liberated from the all-devouring tyranny of Athens. Now, however, Sparta, although tilled to redeem these pledges. On the contrary she aimed at setting up a tyranny of her own. Oligarchical governments were established, controlled in each city by a Spartan garrison under a Spartan haimost or military governor. The earliest and one of the worst cases was the tyranny of the thirty tyrants at Athens, set up by Lyandier, and supported by Spartan arms until, after eight months, the Athenian exiles under Thrasybulus marched from Phlyo upon Athens. The Athenian democracy was formally restored in September 103 B.C., and the liberators used their victory with a wise moderation. Four years later Sparta was put to death, because a party blindly zealous for the old beliefs of Athens could not see that such thought as his led to the only firm basis for a new social order.

The istant of the 10,000 Greeks under Xenophon, in 401 B.C., marks a turning-point in the relations of Greece to Persia. It was to the Greeks a striking revelation of Persian weakness, an encouragement to schemes of invasion which would before have seemed wild. Sparta now began a war against the Persians in Asia Minor—partly to escape from the reproach of having abandoned Asiatic Hellas to the barbarian Agemians, on whom the Jason of the famous retreat had not been lost, was encouraged by success to plan a bolder campaign. But in 394 B.C. the Athenian Conon, commanding the fleet raised by the satrap Pharnabazus, utterly defeated the Spartan fleet at Cnidus. Soon afterwards, under his protection, the Long Walls of Athens were destroyed. The Spartan power in Asia Minor was at an end. The oligarchies were overthrown, and the Spartan governors expelled.

The istants of Sparta did not end here. At the instigation of Persia an alliance was formed between Athens, Thebes, Argos, and Corinth. In the territory of the latter state the allies waged war on Sparta, to whose aid Agemians was recalled from Asia. When the Corinthian War had lasted six years, the peace of Antalcidas was negotiated between Sparta and Persia (387 B.C.). By this Greek cities in Asia, with Cyprus, were given up to Persia. Lemnos, Imbros, and Scyros were assigned to Athens. All other Greek cities were declared independent. The meaning of this was that they were to be independent of each other—isolated for purposes of defence—and all alike dependent on the Great King. The Corinthian War had begun from Persian intrigue, it ended with a peace dictated by Persia. But the Spartan policy had gained its own ends. The so-called "autonomy" of the Greek cities disarmed the rivals of Sparta. Now, as at the end of the Peloponnesian War, a prospect of dominion was opened to her. The Persian king, whom this disgraceful peace practically recognised as suzerain of Greece, was to be merely the guarantor of terms under which Spartan ambition might be securely pursued.

A few years later these designs met with their first serious check. In 382 B.C. the Spartans treacherously seized the Cadmea or citadel of Thebes. They held Thebes for three years. But in 379 a party of Theban exiles, under Pelopidas, surprised the Spartan garrison and recovered the city. A still greater discouragement to Sparta was the establishment of a new Athenian Confederacy—precautions being taken against the members passing, as under the Delian Confederacy, into the condition of mere tributaries. Thebes joined the new confederacy, and presently succeeded in restoring the old Boeotian league, of which Thebes was the head. But the rise of Thebes had excited Athenian jealousy. Peace was made in 371 between Athens and Sparta. Thebes, thus isolated, was at once attacked by the Lacedaemonians. They invaded Boeotia, but were de-

feated by the Thebans under Epaminondas at Leuctra, Thelion 371 B.C. This destroyed Spartan power outside of the Peloponnesus. Epaminondas next attacked the Peloponnesian states itself. He resolved to set up rivals to Sparta on her own borders. He therefore united the cities of Arcadia Epymia into a league, with a new city, Megalopolis, for its capital, and he gave independence to Messenia, which for three centuries had been subject to Sparta—laying the foundations of a new capital, Messene, around the great natural citadel of Ithome. The Arcadian league did not long hold together. Mantinea led a group of Arcadian towns favourable to Sparta. In 362 B.C. a battle was fought near Mantinea between the Spartans and the Thebans. The Thebans were victorious, but Epaminondas fell. With his death the temporary supremacy of Thebes came to an end. Sparta had, however, been reduced from the rank of a leading state. Xenophon closes his *Hellenica* with these words—"There was more confusion (*ἀσφαλεία*) and tumult in Greece after the battle than before."

Political confusion is indeed the general characteristic of the period between the end of the Peloponnesian War and the Macedonian conquest of Greece. In the preceding century Athens and Sparta had been the vigorous representatives of two distinct principles. This oligarchic cities rallied round Sparta, the democratic round Athens. But at the end of the Peloponnesian War Athens was exhausted, Sparta now predominant, but suffering from inner decay, exercised her power in such a manner as to estrange her natural allies. Thus both the normal groups of states were broken up. New and arbitrary combinations succeeded, seldom lasting long, since they were prompted merely by the interest or impulse of the hour. In this period of unstable politics the moment most promising, perhaps, for the future of Greece was when Athens had formed a new naval confederacy, and was also allied with the Boeotian league. But this alliance was broken by Athenian jealousy of Thebes,—not to be renewed until Greek independence was on the eve of receiving its death blow. The work of Epaminondas in one sense did with him, the brief hegemony of Thebes passed away. But in another sense the results which he achieved were enduring. He had been for Thebes such a man as Pericles was for Athens—a ruling personal influence in a democratic commonwealth, and he had raised Theban policy to the old Athenian level. The aims of Thebes were no longer confined to the circle of Theban interests, Thebes now aspired to be what Athens had been—the champion of national freedom and greatness. The power founded by Epaminondas was transient, but this large Hellenic patriotism made itself felt in some degree as a permanent inspiration, preparing the Thebans to stand by the Athenians in the last struggle for Greek freedom.

VI. The reigns of Philip and Alexander, 359-323 B.C.

Three years after the death of Epaminondas Philip came Decey of to the throne of Macedon. His power rapidly grew. A of Greek warlike people, ruled by an able and ambitious king, was now the northern neighbour of Greece. The most obvious vice of Greek politics at this period was disunion, but the disunion itself was only the symptom of a deeper decay. No one city of Greece any longer retained the vigour loquised in a leader. Had either Athens or Sparta now possessed such vital force as they showed in the Persian wars, no local or temporary faults would have prevented the organisation of national defence. Nothing marks the decay of the Greek commonwealths more significantly than the fact that they did not even recognise the urgency of the danger. Demosthenes had the old Greek spirit, but he Demosthenes stood almost alone. The principles on which he constantly insisted, and which give unity to his entire career, are mainly

two — first, the duty of the Athenian citizen to sacrifice personal ease and gain to the service of Athens, secondly, the duty of Athens, as the natural head of free Greece, to consult the interests of all the Greek cities. The energy of Demosthenes was not first roused by the progress of Philip. Before there was danger from the quarter of Macedonia, Demosthenes had seen clearly that the decay of public spirit threatened the destruction of Hellenic life. As he said to the Athenians afterwards, if Philip had not existed they would have made another Philip for themselves. And the condition of Athens was at least not worse than that of any other city which could have aspired to lead.

Philip A strategist so keen sighted as Philip must early have perceived that he had little to fear from combined resistance, so long as he was careful not to attack too many separate interests at the same time. Greece, he saw, was just fighting for each other as Greeks. This was the key-note of his policy to the last. While making aggressions on one Greek city or group of cities, he always contrived to have others on his side.

First period of his reign in Greece, 359-346 B.C. Philip's career in relation to Greece has two periods. The end of the first period is marked by his admission to the Amphictyonic Council, the end of the second, by the battle of Chaeronea. During the first period Philip is still a foreign power threatening Greece from outside. He takes Amphipolis from the Athenians, he destroys Potidaea, he acquires towns on the Thracian and Macedonian coasts, he defeats the Phocians under Onomarchus, and even advances to Thermopylae, to find the pass guarded by the Athenians. Finally, he destroys Olynthus and the thirty-two towns of its confederacy.

Second period, 346-336 B.C. In the second period he is no longer a foreign power. Having intervened in the Sacred War and crushed the Phocians, he has taken the place of Phocis in the Amphictyonic Council, and has thereby been admitted within the circle of the Greek states. The First Philippic and the three Olynthian speeches of Demosthenes belong to the first of these periods. The speeches On the Peace, On the Embassy, On the Chersonese, and the two later Philippics, belong to the second. In the Third Philippic, the climax of his efforts before Chaeronea, Demosthenes reviews the progress of Philip from the Hellenic, not merely from the Athenian, point of view. Philip has destroyed Olynthus, he has ruined Phocis, he has sown dissensions in Thessaly, Thebes is afraid of him, he has gained Euboea and the Peloponnese, he is supreme from the Adriatic to the Hellespont, and the last hope of Greece is in Athens. Demosthenes succeeded in winning back Byzantium to the Athenian alliance, and in persuading Thebans to fight by the side of Athenians, but he could not avert the catastrophe of Chaeronea.

Philip president of an Hellenic league After the victory which made him master of Greece, Philip deprived Sparta of her conquests in the Peloponnese. The Messenians, Arcadians, Argives, recovered their old possessions. A congress was then summoned at the instance of Corinth. Macedonia and the Greek states were united in a federal league. A federal council was constituted to guard the federal laws, and the Delphic Amphictyony was recognized as a tribunal to which this council should refer any breach of those laws. Philip, representing Macedonia, the most important member of the league, was acknowledged as its head or president. His position in regard to the Greek cities was thus in form much the same as that of Athens or Sparta in former days. It was nominally an hegemony, with somewhat more stringent powers, corresponding to the more systematic organization of the league, in practice it was military kingship over Greece. Yet Demosthenes had not failed. The condition of the Greek states under Philip was favourable in proportion as they had given him trouble. Thessaly had actively helped him, and had been completely subjugated.

getal The Peloponnesian rivals of Sparta had not been active either in helping or resisting him, and they were now more dependent on Philip than they had formerly been on Sparta. Athens alone had effectively resisted him, and Athens was treated by him with the prudent respect due to a serious antagonist.

It Greek liberty had received a fatal blow in Greece itself, proper, there was another part of Hellas in which, almost simultaneously, it had been vindicated with splendid success. While Demosthenes was making his heroic resistance to the designs of Macedonia, the enemies of Hellenic freedom in Sicily had been encountered with equal vigour and happier fortune by Timoleon. A few years after the defeat of the Athenian armament in 413, Sicily had suffered two invasions of the Carthaginians. Salinus and Himera, Agrigentum, Gela, and Camarina, had successively fallen. The first Dionysius, in consolidating his own tyranny at 405-367 Syracuse, had been content to leave half the island in the hands of the foreign foe. The feeble marionette of his son, Dionysius II., produced a series of revolutions. A party at Syracuse invoked the aid of Corinth. Timoleon was sent with only 1200 men (343 B.C.). His first work was to deliver Syracuse from the contending forces of Dionysius and a rival named Hieretas, and to restore the Syracusan democracy. His next work was to drive the Carthaginians out of Sicily. He defeated them with a crushing effect at the river Crimessus (340 B.C.). The Sicilian Greeks were now free. Sicily entered on a new period of prosperity, which lasted until Agathocles became tyrant of Syracuse (317 B.C.). Thus the brightest days, perhaps, of Hellenic Sicily coincided with those in which the cities of the Hellenic mainland were learning to bear the Macedonian yoke.

The time seemed now to have come for an enterprise which, since the retreat of the Ten Thousand, had been the dream of many Greek captains, but which none had yet been in a position to attempt. Philip, in the forty-seventh year of his age, had declared war against Persia, and was preparing to invade Asia at the head of an army gathered from all Greece, when he was assassinated by a young Macedonian noble in revenge for a private affront (336 B.C.). Death of Alexander, Philip's son and successor, was only twenty Philip Matching into Greece, he promptly expressed an insurrectionary movement, and was recognized by a new assembly at Corinth as commander-in-chief of the Greek armies. He next marched against the tribes on the northern borders of Macedonia. While he was absent on this expedition, the Thebans rose against the Macedonian garrison. Alexander returned, took Thebes, and laid it to the ground (335 B.C.). At Corinth he received the homage of the Greek states, and then returned to Macedonia.

Alexander was now free to execute this design of Philip. As captain general of Hellas, he set forth to invade the Persian empire, and to avenge the wrongs suffered by Greece at the hands of the first Darius and of Xerxes. The army with which he crossed the Hellespont in 334 B.C. numbered perhaps about 30,000 infantry and 4000 cavalry. It was composed of Macedonians, Greeks, and auxiliaries from the barbarian tribes on the Macedonian borders. The devotion of native Macedonians to their hereditary king was combined with the enthusiasm of soldiers for a great general. Even if the military genius of Alexander had not been of the first order, his personal authority over his Macedonian troops, and through them over the rest, would still have been greater than was ever possessed by a Greek citizen commanding fellow-citizens.

Alexander's career of conquest has three stages, marked by his three great battles. The victory at the Granicus (334 B.C.) gave him Asia Minor. The victory at Issus (333 B.C.) opened his path into Syria and Egypt. The victory

These stages of his career

Alexander invaded Asia

at Arbela (331 B.C.) made him temporary master of the whole East. In accomplishing the first two of those stages, Alexander was not compelled to assume any new character. The king of Macedonia, the elective captain-general of Greece, needed no other titles by which to hold the lands to which he came as a deliverer from Persia. The later history of these lands is the pivot Asia Minor was by degrees thoroughly Hellenized, and remained Greek till the Turks came in the 11th century. Syria and Egypt were not indeed Hellenized as whole countries, but their capital cities, Antioch and Alexandria, were Hellenic, and the control established by Alexander was retained by Seleucus or by Rome for centuries. At the third stage, however, Alexander's conquests entered upon an entirely new phase, and compelled him to take up an altogether new position. Neither in his Hellenic nor in his Macedonian capacity could he put forward any effective claim to hold the Persian empire proper,—the empire stripped of its Egyptian, Phoenician, and Hellenic dependencies. He could hold Persia only as a Persian king, as the successor of those Achaemenid kings whose dynasty he had overthrown. The constitutional king of Macedonia, with limited prerogatives, the elective captain of Greece, must now assume a third and distinct character. He must be also a Persian king, a constitutional one. The mostly European influences represented by Alexander might leave the East, but they could not lastingly possess or transform it. Hellenic cultivation, like Roman power, was not permanently introduced over any wide area east of the Euphrates. This fact is enough to illustrate the enormous difficulty of the task which Alexander had undertaken. It seems not impossible that policy may have been mingled with vanity in his execution of divine honours. Greeks or Macedonians could never pay him the slavish homage which Persians subjected to their king. But the contrast between European and Asiatic royalty would at least be less glaring if the master of Persia were also acknowledged as the son of Zeus Ammon.

Greek
enemies in
Asia:

The colonies planted by Alexander in his progress through Asia mark the beginning of a new period in Hellenic history. Hitherto we have had to do with a people whose Hellenic unity rests, not merely on community of language and civilization, but also upon community of blood. Now, by the side of this natural Hellenic nation, there arises an artificial Hellenic nation, with a common language and civilization, but not exclusively of Hellenic blood. The Macedonians may be regarded as the founders of this artificial nationality. They were doubtless of a stock kindred to the Hellenic, in what degree, it is less easy to say—but (with the exception of their kings) they were generally regarded by the Greeks as standing half-way between Greeks and barbarians. Philip did much to Hellenize Macedonia, and the Macedonian colonies of Alexander became in their turn centres from which the influence of Hellenic civilization was diffused through Asia. Henceforth there are two Hellenic types: the Greek of Greece proper, who preserves in some degree the marked individuality of the old Greek character, and the Asiatic Greek, more readily affected by foreign surroundings, more pliant and less independent. The history of the modern Greek nationality dates from the days of Alexander.

Results
of Alexander's
conquests

The results of Alexander's conquests were beneficent chiefly in two ways: first, by liberating the hoarded treasures of the Eastern kings, and so stimulating industry and commerce; secondly, by opening Asia to a new civilization, which helped to promote intellectual and moral progress, even in those places where its influence was limited or transient. In the process of doing this much that was valuable may have been destroyed. But it can hardly be questioned that on the whole the gain far outweighed the

loss. If Alexander had not died at the age of thirty-two, leaving his work unfinished, it would perhaps have been easier to judge how far he deserves the credit of having contemplated these benefits to mankind. There is nothing to show that he intended to govern otherwise than as an absolute ruler, with a better machinery for controlling his subordinates than had been possessed by the Persian kings. Such a view is not inconsistent with the fact that his colonies enjoyed municipal freedom. Nor can it be proved that he meant his colonies to be anything more than military strongholds or commercial centres. But it may at least be said that, if his object had been to diffuse Hellenic civilization over Asia, he could have adopted no more effective means. It is conceivable that, in his vision of that complex empire which imposed such almost unreasonable tasks upon its ruler, the idea of engraving Eastern absolutism on Greek politics may have co-existed with the idea of Hellenizing Asiatic society.

In that period of Hellenic history which closes with Alexander we are tracing the gradual development of a race with special gifts of mind and body, which strongly distinguish it from all other races. The Hellenes set the Hellenic stamp on everything which they create,—first, on their language itself, then on their politics, their literature, and their manners. Every element of their life receives its mature shape from themselves, even when the germ has been borrowed, the Hellenes are an original people in the sense that they either invent or transform. At a very early time they have the political life of cities, and they never rise from the conception of the city to the higher unity of the nation. Their love of clear outline and their sense of measure shrink from every vague abstraction, the principle of order itself is by them identified with "the limit", the indefinite is a synonym for disorder and evil. The city, an easily comprehended whole, satisfies this instinct, but there is room within its framework for the gradations of monarchy, oligarchy, democracy, for the various modes of acting and thinking which characterize Achæans, Dorians, Ionians. As the leading commonwealths grow to maturity, two principles of government stand out in contrast,—oligarchy and democracy. Each is represented by a great city round which the lesser states are grouped. The inevitable collision comes, and the representative of democracy is at last vanquished. But in the hour of victory oligarchy is discredited by the selfish ambition of its champion. A time of political confusion follows, in which no one can keep a leading place. Separate cities, separated by new principles, public unity declines. The disunion of the cities—incurable, because arising from a deep inner deny—enables the crafty king of a half-barbarian country to make himself the military dictator of Greece. But just when the better days of Hellenic civilization seem to be over, a new career is opened to it. Men who are not of Hellenic blood help to diffuse the Hellenic language, thought, and manners over a wider field, and the life of the modern Greek nation begins. (B.C. 3)

SECTION II.—POST-CLASSICAL GREEK HISTORY

The later history of the Greeks, from the end of Alexander the Great's reign to the taking of Constantinople by the Turks, may be divided most naturally into five periods, viz.—I. The period of Greek subjection from the death of Alexander to the accession of Constantine the Great as sole emperor, 323 B.C. to 323 A.D. II. The period of Greek revival from Constantine the Great to Leo III (the Isaurian), 323–718 A.D. III. The period of Byzantine prosperity from Leo III to Isaac I (Comnenus), 718–1057 A.D. IV. The period of Byzantine decline from Isaac I to the taking of Constantinople by the Latins,

1037-1204 A.D. V The period of Greek survival from the taking of Constantinople by the Latins to its conquest by the Turks, 1204-1453 A.D.

In the limited space of an article like the following, it is impossible to enter into detail with reference to the events of any of these periods. It may be well therefore if we turn our attention especially to the causes which were from time to time at work, to the characteristics and tendencies of various ages, and to the changes that came over society

The history which we thus enter upon is of importance and interest in a different way from that of the classical age of Greece. That age was a unique development in respect of national life and character, of social and political institutions, and of every form of cultivation, and was marked by concentrated energy and intense vigour. The later period is important because of its wide-reaching influence on the world at large, and because it is one, and that the more continuous, of the two great chains of events, in eastern and western Europe respectively, which connect the earlier and later history of civilized man.

To the younger student, who is already acquainted with the previous history of Greece and Rome, and has learnt something of the condition of the modern world through the history of England, no other period is probably so instructive and suggestive. He is led into byways of history and remote countries, which have in themselves an element of romance. He comes into contact with races from every branch of the human family in the freshness of their early vigour, and amongst many other lessons he learns one, which cannot be learnt too early, and which historians and students of history are disposed to overlook, that the unfortunate are not therefore to be despised. To more advanced students its value consists in its explaining the existing state of things in a considerable part of Europe and Asia, which cannot be explained otherwise, and still more in the illustrations it affords, both by way of similarity and contrast, to circumstances in the history of western Europe, such, for instance, as the abolition of serfdom, the relations of immigrant races to the original inhabitants, and systems of law and finance.

Besides this, so much civilization filtrated from the East to the West in the course of the Middle Ages that a knowledge of Byzantine history is necessary to a proper understanding of that of western Europe. It will suggest also, if properly studied, that while battles, sieges, and other salient events may be the turning-points of history, the inhabitants of any particular country are more affected by influences which lie below the surface—by alterations of trade routes and changes in the tenure of land, by the effects of judicious or injudicious taxation, by the administration of justice, and by the relations of different classes to one another.

It is desirable at stating to notice two misconceptions which have prevailed, and in a less degree still prevail, with regard to different portions of this period. The first of these concerns the character of the Greeks during the time of their subjection to the Romans, and in particular under the early emperors, in which age they are often supposed to have been a demoralized and unprincipled race. Such expressions as the "Greculus senilis" and "Grecia mendax" of Juvenal, and similar ones which are found in Tacitus and other writers of that time, have become proverbial, and have been taken to describe, as those authors undoubtedly intended them to describe, the people at large. There was some justification for the remark of Lucian, that the Romans spoke truth only once in three lives, and that was when they made their wills. The fact is that these descriptions represented faithfully enough the lower class of Greek adventurers who came to Rome from Alexandria and the Asiatic cities to seek their fortunes, and the Roman writers, with their usual contemptuous ignorance of

anything provincial, confused these with the Greek nation. The latter Greeks no doubt had degenerated from their great forefathers, but it is only fair to remember that this was to a great extent the result of their circumstances. The rapid growth of Greek culture and Greek political ideas was naturally followed by rapid decay. In sculpture the early archaic style developed in a few decades of years into the manly and perfect style of Phidias, and the change was equally rapid to the luxurious style of Praxiteles in which the elements of decadence were already traceable. The same thing is apparent in the history of the drama. And in like manner in politics, the constitutions of the various states, which were so well suited to the development of Greek individuality, contained in themselves no element of permanence, owing to the opposing elements which were brought face to face within so narrow an area, and in their relations to one another, all combustion on a large scale was prevented by what has been aptly called the "centrifugal" character of Greek politics, so that they were destined inevitably to fall under the dominion of any great empire that should arise in their neighbourhood. Again, it must never be forgotten that the splendid products of Greek genius and Greek character sprang from the black soil of slavery, and could not have existed without it, so that here too we find an element of rottenness, which was sure in the end to produce decay. Consequently, from the time the Greeks lost their liberty, they could in all fairness be judged by a different standard from their predecessors, and we ought to be satisfied if we find in them such good qualities as characterize a more ordinary people—industry, respectability, intelligence, good citizenship, capacity for local self-government, and readiness to make the most of their opportunities. In all these respects the Greeks were among the best of the provincials of the Roman empire.

The other misconception relates to the Byzantine empire, which has been commonly regarded as a period of steady decline and feebleness and decrepitude. The author who is mainly responsible for the prevalence of this view is Gibbon, and it is strange that a writer who was gifted with such profound historical insight should not have perceived that the state which accomplished such great things could not have been powerless. The passage in which he expresses himself on this subject is well known. "I should have abandoned without regret," he says, "the Greek slaves and their servile historians, had I not reflected that the fate of the Byzantine monarchy is passively connected with the most splendid and important revolutions which have changed the state of the world." Yet it was the same empire which beat back for centuries, and ultimately survived, first the Sassanids and afterwards the Seljuks, and of which peoples would otherwise have overrun Europe, and which, even in its decline, kept at bay, for more than a hundred years, the Ottomans when at the height of their power, thereby providing the Western nations with a breathing space, without which the career of Turkish conquest would certainly not have been arrested at Vienna, but might have extended to the Elbe or the Seine. During the 8th, 9th, and 10th centuries its military power was the strongest in Europe, and the individual prowess of its aristocracy was unrivalled, while at the same time its long succession of able emperors and administrators is such as no other monarchical government can show. Its influence is further shown by its missionary efforts, resulting in the conversion to Christianity of the south Slavonic nations and the Russians, and the consequent spread of civilization throughout the countries they inhabited, by its widely extended commerce both by land and sea, and by its art, especially its architecture, which contributed to the formation of other styles from Egypt to the north of Russia, and from India to Spain. Finally, its social and political excellence

appears in the state of education, in the regularity of its administration, especially in the matter of justice, and, above all, in the legal standard of the *canon law*, maintained inviolable from first to last, which is a sure proof of a highly organized system. When its situation in the midst of barbarous nations is considered, and the intermediate position it occupied between Asia and western Europe, it may safely be pronounced one of the most powerful civilizing agencies that the world has seen.

I *Period of Greek Subjection from the Death of Alexander to the Accession of Constantine the Great as sole Emperor, 323 B.C. to 330 A.D.*

Effect of Alex-
ander's con-
quests

The conquests of Alexander the Great diffused from those of almost every other great conqueror in this that they were followed up by a scheme of civil government, the object of which was to secure the well-being and promote the civilization of all his subjects. That he was not the ambitious madman which he is often represented as being is amply proved by the foresight with which his campaigns were planned, and by his attention to the commissariat and to other details connected with the transport and maintenance of his vast armies. But his true greatness is most clearly shown by his endeavouring to introduce unity into his vast empire, not by subjecting one race to another, or crushing out the hope of further resistance by an iron rule, but by establishing in its centre of permanent institutions and common culture. These were the Greek colonies with municipal government which he founded at intervals throughout Asia. By these the subject countries, without being forced into a common mould, or organized in defiance of their feelings and prejudices and without reference to their national institutions, were gradually leavened by the system that existed among them, and obtained a certain infusion of the Hellenic character and Hellenic modes of thought. Though Alexander himself did not survive to complete his project, yet enough had been accomplished at the time of his death to leave its influence firmly imprinted, even when his empire fell to pieces and was partitioned among his generals. The consequences of this to Asia were of incalculable importance, and continued unimpaired until the tide of Mahometan conquest swept over the country, and even then it was from Greek literature and art that the Arabs obtained the culture for which they have been celebrated. But its effect was hardly less marked on the Greeks themselves. The Hellenic world was henceforth divided into two sections—the Greeks of Greece proper, and the Macedonian Greeks of Asia and Egypt. Between these there existed a common bond in similarity of education, religion, and social feelings, in the possession of a common language and literature, and in their exclusiveness, whether as a free population living a large slave element, or as a privileged class in the midst of less favoured races, but the differences were equally striking. The former retained more of the independent spirit of the ancient Greeks, of their moral character and patriotism, the latter were more cosmopolitan, more servile, more ready to take the impress of those among whom they were thrown, in them the Ulysses type of Greek character, if we may so speak—its astuteness and versatility—became predominant. This distinction is all-important for the subsequent history, since, in the earlier period, it is rather the Greeks of Iliad who attract our attention, whereas after the foundation of Constantinople the Macedonian Greeks occupy the most prominent position. At the same time a change passed over the Greek language; while the ancient dialects were retained, more or less, in the provinces of Greece proper, the Attic dialect became the court language of the Macedonian monarchs, and was used almost exclusively by prose writers. Gradually Macedonian and other provincial

isms crept into it, and it was modified by simpler expressions, and words in more general use, being substituted for those preferred by the classic writers of Athens, and thus was formed what was called the *common* or generally used dialect. The non-Greek inhabitants of the countries in which the Greeks were settled were described as "Hellenizing," and consequently their language, such as we find it in the Septuagint and the New Testament, was called Hellenistic Greek. The literary spirit also migrated to Alexandria, which became for a time the home of the principal Greek culture, and nurtured the genius of Theocritus, the first of pastoral poets, the taste and tradition of Aratus and Apollonius Rhodius, and the research of Aristarchus and other eminent Hellenic critics.

The period of somewhat less than two centuries (323-146 B.C.) which intervened between the death of Alexander and the conquest of Greece by the Romans was a sort of twilight between liberty and subjection. The Lamiæ War, as the contest between a number of the Grecian states, with Athens at their head, and Antipater, one of Alexander's immediate successors in Macedonia, was called from the siege of Lamiæ, which was its most prominent event, soon convinced the Greeks that it was idle for them to struggle single-handed with their great neighbour. After that the country formed a bone of contention between the neighbouring potentates in Macedonia, Asia Minor, Syria, and Egypt, and most of the states, with the exception of Sparta, who in the power sometimes of one sometimes of another of them, through the contests of their masters secured them from time to time a partial independence. At length the constant danger to which their liberties were exposed suggested the necessity of some kind of combination or the part of the separate states, and the famous Achaean league arose (280 B.C.), which revived the dying energies of the Greeks, and has thrown a lustre over their period of decline. For the origin of this federation we must go back to the early history of the district of Achaia in northern Peloponnesus, the inhabitants of which, from being isolated from other races by their position between the Arcadian mountains and the Corinthian Gulf, and occupying a succession of valleys and small plains, found a federal union to be the most natural political system by which they could be held together. Throughout the greater part of their history this people exercised little influence on the fortunes of Greece, but in her time of greatest need they came forward as her champions. The league was now revived, with a more definite organization and a wider political object, and under the leadership of Aratus, the greatest of its early "strategi," it wrested Sicyon from the power of its tyrant, and Corinth from the hands of the Macedonians, until at last it embraced Athens, and almost the whole of the Peloponnesus. Unfortunately Sparta held aloof. That city, which had succeeded in maintaining its independence, had fallen into the hands of a narrow oligarchy of wealthy proprietors, who rose in violent opposition to their reigning kings—men whose names would be a glory to any period—Agas and Cleomenes, and succeeded in putting the first to death, while the latter was enabled to overpower them through the influence won by his military successes. But circumstances involved Aratus in a war with Sparta, and here the old Greek spirit of discord betrays itself. When hard pressed by Cleomenes, the Achaean leader applied to the Macedonians, and the result was that Antigonus Doson invaded the country, and at Sellasia inflicted a final and crushing blow on the Spartan power (221 B.C.). The same spirit repeats in the Social War, which occurred shortly after this between the Achæans and the Ætolian league, a similar confederation in northern Greece, and was fomented by Philip V. of Macedon. Subsequently, when the Romans made war on Philip for assisting the Carthaginians in the Second Punic War, the consul

Flamininus persuaded both these powers to join in attacking him. At Cynoscephalæ in Thessaly, not far from the scene of a greater battle, Phœnix, the power of the Macedonian monarchy was broken (197 B.C.), and Philip renounced his superiority over the Greeks, to whom Flamininus proclaimed their freedom at the ensuing Isthmian games. The final overthrow came in the time of Perseus, the son of Philip, who was defeated at Pydna (168 B.C.), and his dominions, with the adjacent parts of Greece, were reduced to the form of a Roman province. The later years of the Achaean league, had been illumined by the leadership of Philopomenus, "the last of the Greeks," as Plutarch has called him, in whose time the whole of the Peloponnese, including even Sparta, was for a time included in the alliance. But the days of Greece were numbered, and the only question was how soon the remainder should be absorbed by the advancing tide of Roman conquest. At first a pretext for interference presented itself, and the reduction of the country to bondage was signalled by the pillage and destruction of Corinth under Mummius (146 B.C.). The entire area southward of Macedonia and Epirus was constituted the province of Achæia, the title of which perpetuated the name of the Achaean league. The struggles in which that and the Egean confederation had taken part are an evidence of the revival of a spirit of patriotism in the breasts of the Greeks, and they were well lamented over the ruin of their independence, but the truth must be told that this was not the feeling of the majority of the population at the time. The selfishness and cupidity of the Greek aristocracy, such as those whom we have already noticed at Sparta, had imposed so heavy burdens on the people that the great body of them cheerfully acquiesced in the Roman rule. Polybius has preserved to us the saying which expressed the sentiment of the time. "If we had not been quickly ruined, we should not have been saved."

From the time of the Roman conquest the existence of Greece was merged in that of a greater political unity, so that for the next four centuries, until the commencement of the barbarian invasions, it can hardly be said to have a history of its own. But we must not on this account suppose that the Greeks occupied exactly the same position as the rest of the Roman provincials. In this respect there is a marked difference between the results of the Roman conquests in the West and the East. The inhabitants of the western portion of the empire were at the time of their subjection in a low state of civilization, and destitute of any element of strength in their social and national life. It was natural, therefore, that nations so undeveloped should easily receive the impulses of Roman institutions, and should adopt the manners and ideas of their conquerors. The Romans in fact treated them for the most part as inferior beings and did not at first even regard them as absolute proprietors of the lands they cultivated. But in the East the case was different. These the Romans met with a civilization more advanced than their own, which they had already learned to respect, and an elaborate system of civil government and social usages which could not be set aside without undermining the whole fabric of society. Hence the Greeks, while subjected to the Roman administration, were allowed to retain a great part of their institutions, together with their property and private rights, and from their superiority to the other conquered peoples, remained the dominant power in the East. Even in Asia the despotism of Rome was much modified by the municipal system of the Greek colonies and by the influence of Greek culture. Thus it came to pass that, while the Western nations were assimilated to Rome, in the East the Roman empire became Greek, though the Greek nation in name became Roman. The effects of this are visible at every turn in the subsequent history, and to this cause must be referred many anomalies

which are traceable at the present day in the condition of eastern Europe.

It was a part of the Roman policy, in dealing with conquered countries, to treat them at first with mildness, until they became inured to the yoke, and when this was the case, and precautionary measures had been adopted to prevent the possibility of successful revolt, to deal with them more harshly and increase their burdens. Thus was what happened in the case of Greece. For some time the people at large had no reason to regret the change. The fact of their subjection was not impressed too forcibly upon them, and several cities, such as Athens and Sparta, were allowed to rank as allied states. Their taxes were not too onerous, and they did not at once perceive the difference caused by the money that was levied being taken out of the country instead of being spent in it. This was, however, the most systematically ruinous part of the Roman system. The Government never paid attention to the provinces for their own sake, but regarded them as an instrument for maintaining the greatness and power of Rome. The immense sums that were diamined from them never returned, but were expended in the maintenance of the Roman army, and in the public games and architectural embellishment of the metropolis. Objects of local usefulness, such as roads, ports, and aqueducts, received no attention from the central authorities, and no money was supplied towards their maintenance. Within a century after when the Romans were beginning to make themselves felt, the Roman rule became very oppressive. Though the custom duties were not unreasonable in their nominal amount, they became exorbitant through the system of farming and subletting, and as a special tribunal existed for the enforcement of the collectors' claims, the farmers exercised a most tyrannical power over the mercantile population of the shores of the Mediterranean. In the wake of these harpies followed the usurers, to meet whose claims proprietors had constantly to sell their possessions. The direct weight of the public burdens was further increased by the exemptions enjoyed by Roman citizens in the provinces, and by privileges and monopolies which were granted to merchants and manufacturers, and large sums had to be paid to the Roman governors, both for the maintenance of their establishments, and to obtain exemption from the quartering of troops. But these more or less authorized exactions bore no proportion to the illegal extortions of the proconsuls, who simply pillaged the provincials. No more perfect scheme could have been devised for promoting oppression than that under which these officers were appointed. While on the one hand they superintended the financial administration, on the other they exercised the judicial power, and the only tribunal to which they were responsible was that very senate by which they were appointed, and of which they themselves were members. A governor like Verres had it in his power to ruin a province for several generations, and such instances were not rare. The treatment of Greece in this respect was no exception to the general rule.

The period, however, during which the greatest injury was inflicted on Greece was that of the Mithradatic War (86 B.C.). At the commencement of that struggle many of the leading men and states declared in favour of Mithradates, thinking that under his auspices they might regain their freedom. But the appearance of Sulla with an army soon undeceived them, and they laid down their arms, with the exception of Athens, which was only reduced after an obstinate defence. When the city was at last taken by storm, the majority of the citizens were put to the sword, their possessions seized by the soldiers, the Treasuries utterly destroyed, and Attica ravaged. In the same campaign Delphi and the other principal shrines were plundered, and an immense amount of property was used throughout the

Roman rule in Greece

country. Great injury was also inflicted by the Cretan pirates. The evidence of these was a result of the policy with which the Roman Government regarded the maintenance of armed forces by the provincials, either by land or sea, lest they should be made an instrument of rebels, and since they had no interest in maintaining order, except where their own authority was threatened, the subject nations were so far from profiting by their protection that they were exposed to attack without possessing the power of defending themselves. The confined seas and numerous bays and islands of Greece have always been favourable to piracy, and at this time the evil reached such a height that the welfare of the state was threatened, and Pompey was entrusted with the office of eradicating it, but before this was accomplished many of the wealthiest cities in Greece and Asia Minor had been attacked and pillaged. With the accession of Augustus a brighter era seemed to have dawned, and under the early emperors, who desired to strengthen themselves against the senate, the interests of the provincials were more considered. Greater regularity also was introduced into the taxation, by the land and capitation taxes being regulated by a periodical census. But the old evils to a great extent remained, and these were further aggravated at a later time by the depredation of the Goths, which proceeded with fearful rapidity, and caused widespread distress among the commercial and labouring classes.

Constitution and character of the Greek people.

The result of these changes is traceable in the condition and character of the Greek people. The conquests of Alexander the Great suddenly threw into circulation the accumulated treasures of the Persian empire, and a great part of these passed into the hands of the Greeks, both in Asia and Europe. The facilities thus created for obtaining wealth increased the material prosperity of the Greek race at large, so that in all probability it never was more numerous than during the period immediately preceding its subjugation by the Romans. Though all calculations respecting the numbers of the population in ancient states are necessarily hazardous, yet it seems probable that the Greeks at that time may have amounted to more than seven millions. But with Greece proper the case was different. The increase of wealth raised the standard of living considerably above what it had been in earlier and more frugal times, so that the less moneyed class were tempted to emigrate in large numbers to seek their fortunes in the great Asiatic cities, and in the service of the Eastern monarchs, where so great openings presented themselves. The decrease of this class produced a larger accumulation of property in the hands of large owners, and greatly augmented the number of slaves. Under the Romans the wealth of the country, great as it was, was soon dissipated by fiscal exactions, by plunder in war and the private pillage of officials, and by the confiscation of the possessions of individuals, with a view to which a system of accusations was regularly promoted. The natural result of this, combined with the self-indulgent habits which had grown up among the upper classes, was a steady diminution of the population. The first of the Romans who perceived the evils arising from this state of things, and endeavoured to remedy them, was the emperor Hadrian, who had the merit of personally visiting the provinces, and whose tastes naturally led him to sympathize with the Greeks. Though much of the money which he expended in the country in the construction of temples and other splendid edifices tended to the gratification of his private fancy, yet a real improvement in the condition of the people was effected by his restoration of the roads which had fallen out of repair, and the erection of baths and aqueducts. He also lightened the taxation, and raised the Greeks to the rights of Roman citizenship, thereby anticipating the edict of Caracalla, by which that privilege was extended to all the free inhabitants

of the empire (213 A.D.). The depopulation of Greece, however, continued, but while in this way the power of the nation was being weakened, its material resources diminished by the loss of much of the capital that had been invested in the improvement of the country, the actual condition of the inhabitants was for the time improved, because the decrease in their numbers had been more rapid than the destruction of property. Possessing the necessities of life in abundance, and having but little money to spend on anything beyond, they sink into that condition of indifference and ease in which at last the barbarian nations found them.

It has already been remarked that the character of the Greeks at this period ought not to be judged of from the prejudiced statements of Roman writers, nor by reference to the standard of their great forefathers. The introduction of the wealth of Persia had undoubtedly a demoralizing effect on the nation, both in Asia and Europe; but when we consider that throughout a great part of the area that they occupied they were long the dominant class, and had hardly any check to restrain them in the indulgence of their passions, it is rather a matter for wonder that they resisted temptation so far as they did. At least they never sank to such a depth of degradation as the Romans of the imperial times, and in Europe the struggle of the Achaean league show that a value was still set on many virtues. After this the Greeks became the educators of the Romans, whose upper classes resorted for instruction to the university of Athens, and if the rhetoric and philosophy which was taught there partook sometimes of the nature of literary trifling, and the instructors themselves were characterized by vanity and pedantry, they maintained at all events the standard of cultivation in the world at that time. The love of art still prevailed amongst them, and the quiet, studious life of the Greek cities formed in the eyes of many a favourable contrast to the violent struggles and inordinate passions of Rome. But the disbelief in the national religion which had grown up among the educated classes, notwithstanding the maintenance of the temples and their worship, tended to cause a separation between the upper and lower grades of society, and this, together with the isolation produced by the great size of the estates, which withdrew individuals from the scrutiny of their fellow citizens, weakened the force of public opinion, and thus lowered the moral standard. It can hardly be doubted that the consciousness of this, and the feeling of the need of a higher morality, was one main cause of the eagerness with which philosophy continued to be pursued by the Greeks, since in it they hoped to find the groundwork of truth and justice. Thus during a period of six centuries the European Greeks had gradually degenerated, though for the most part from causes external to themselves, they seemed to have become an insignificant and almost commonplace people. Yet the outline of the character was the same, though the colours had faded, and considering the length of the time, and the agencies at work, we may be surprised at finding that the change had not been greater. It remained to be shown that the finer qualities and more vigorous elements were only dormant, and this was brought to light in the latter half of the third century by two influences, which we must now proceed to explain.

The first of these was the invasions of the Goths. These Goths were the earliest of the barbarians to break through the Roman frontier, and the defeat and death of the emperor Decianus (251 A.D.), and the subsequent incursions of the Goths into Thrace and Macedonia, warned the Greeks of the peril that impended over them. Immediately the walls of Athens were repaired, the fortifications across the isthmus of Corinth restored, and vigorous preparations made for defence. The invaders soon made their

appearance both by land and sea, and one division, landing at the Peloponnese, succeeded in capturing Athens, by sea, but in Aidoneus of a rank called *Exsurgens*, afterwards the instrument of the *crisis*, succeeded in assembling a sufficient force to compel them to retire. This reverse was the pledge to them, that, till it occurred, for succours were meanwhile arriving from Italy, by which their separate bands were attacked in detail and destroyed. Some years later, after other misadventures, during which many cities of Greece successfully defended themselves, the power of the Goths was broken by the emperor Claudius II. at the great battle of Naussus (269 A.D.). But it was clearly proved at this time that the spirit of the Greeks, which had had no opportunity of displaying itself since the siege of Athens by Sulla, was not extinct, and that, if they had been unwarlike in the interval, it was mainly because their masters had denied them the use of arms. It is not to be overlooked that, when the same barbarians subsequently attacked the Western empire, it was down before them, the reason being that the nations of the West had no such distinctive nationality as the Greeks, and no such municipal institutions to rally round. Anyhow the Greek character was benefited by the public spirit thus evoked, and by the activity infused into society by the feeling that every man might be called on to defend his person and property.

Christ-
ianity

The other and far more important influence which regenerated the Greeks at this time was Christianity. This religion, which had long been working in secret, though in ways which it is almost impossible to trace, now began to produce a marked impression on Greek society. Its power was the greater, because it had worked from below upward, and had permeated to a great extent the lower and middle classes. It improved the moral condition of the Greeks by elevating their views of life, by quickening the conscience, and by infusing earnestness into the character, and it renovated their social condition by pointing out to them their duties to one another, by encouraging corporate feeling, and in particular by purifying the domestic relations through its influence on the female sex. At the same time the habits of meeting for the administration of their communities accustomed the Christians to discussion and action in common, and the fact that they formed a powerful corporation independent of the state, which was the reason why they were persecuted by the Roman authorities, was in itself a means of political education. Such an influence, which not merely provided every relation of life, but penetrated also to the motives and springs of action, is sufficient of itself to account for the regeneration of the Greeks, which the historian traces in its effects at the end of the 4th century.

The scene now changes, and from the land of Hellas our attention is transferred to the city of Constantinople.

II *Period of Greek Revival from Constantine the Great to Leo III (the Isaurian), 323-716 A.D.*

The principal events of the first half of this period, the two centuries which intervened between Constantine and Justinian, are—the foundation of Constantinople (330 A.D.), the emperor Julian's attempted restoration of Paganism (361), the defeat of Valens by the Goths near Adrianople, and his death (378), the establishment of Christianity by Theodosius the Great as the religion of the empire (383), the partition of the Roman empire between Arcadius and Honorius (393), the publication of the Theodosian code (438), and the extinction of the empire of the West (476). The reign of Justinian (527-565) comprises the great campaigns of Belisarius and Narses, whereby the kingdom of the Vandals in Africa was overthrown, and Sicily, Italy, and southern Spain were recovered to the Roman empire, the Greek possessions in Italy being henceforth governed by an exarch, who resided at Ravenna, the building of

the church of St Sophia at Constantinople, and the reformation of the Roman law. Finally, in the century and a half between Justinian's death and the accession of Leo III, occurred the birth of Mahomet (571), the victorious expeditions of Heraclius against the Persians (622-8) and the seven years' siege of Constantinople by the Saracens in the reign of Constantine Pogonatus (668-875).

The reforms effected by Constantine formed one of the greatest revolutions the world has ever seen, and his sagacity of *Constantine* is shown by the completeness with which they were carried out, and by the permanence of their effects, for from them proceeded both the strength and the impotence of the Byzantine system, which lasted even to the latest days of the empire. To describe them in brief,—he centralized the executive power in the emperor, and constituted a bureaucracy for the administration of public business, he consolidated the dispensation of justice throughout his dominions, he rendered the military power, which had hitherto been the terror and bane of the state, subservient to the civil power, he adopted a new religion, and established a new capital. Henceforth the world was ruled by the emperor and his household, and thus administration was wholly irresponsible, and as the interests of the Government were unconnected with those of any nationality and any class of its subjects, there was sure to be a continual struggle between the rulers and those whom they governed. In order that the emperor might be regarded as a being of a different order from the people, he and his court were surrounded by lavish splendour, and in order to check the ever imminent danger of rebellion through pretenders to the throne, the offices of the court were made magnificent prizes, so that ambitious persons might feel that advancement could be obtained by a safer method than civil war. But to meet these expenses, and at the same time to maintain a powerful army, an elaborate system of taxation was necessary, taxation, in fact, came to be regarded as the first aim of government, and the inhabitants of the empire were impoverished for objects in which they had no direct concern. The principal instrument which Constantine used for enforcing this was the Roman municipal system, and thus he introduced into Greece, notwithstanding the existence of a national and traditional organization. According to this, each town, with the agricultural district in its neighbourhood, was administered by an oligarchical senate called the *curia*, elected from among the landed proprietors, by whom the municipal officers were appointed, and the land tax collected, for the amount of which they were made responsible, while those who did not possess land, such as merchants and artisans, paid the capitation tax, and formed an inferior class. As wealth declined, the oppressiveness of this system was more and more felt, especially as the private property of members of the curia was confiscated when the required amount was not forthcoming, and hence, in order to prevent a further diminution of the revenue, an elaborate caste system was subsequently introduced, which fixed the condition of every class, and required a son to follow the calling of his father, lest the number of persons liable to a certain kind of taxation should decrease. With the same view, the free rural population came to be tied to the soil, to prevent the ground from falling out of cultivation. Since, however, it was foreseen that such a system would produce discontent, the people everywhere were carefully disarmed, and the possession of arms was made a thing apart, the military class being separated from all others. For the same reason barbarians were much used as troops, because they could have no sympathy with the system. The harshness of this system caused general poverty and deep-seated hatred of the central government, often resulting in a disposition to call in the barbarians, while its jealousy was the origin of the weakness of the empire, because the pro-

vincials, who were really stronger than their invaders, were never allowed to defend themselves. In the West it contributed greatly to the overthrow of the empire, and in the East it repulsed the spirit of Hellenic life by intermingling with the ancient city communities, and though the force of the Greek character, and the social condition of the countries they inhabited, saved them from destruction, yet, as we look down the long vista of succeeding ages, we may see its baneful effects producing ever increasing misery.

Yet we must not overlook the strong points of Constantine's system. The first of these was the regular administration of justice which he introduced. This the inhabitants of the empire felt they could not obtain elsewhere, and the possession of it reconciled them to many other less tolerable advantages. So conscious were succeeding emperors of this that we find strictness observed in this matter until quite a late age of the Byzantine empire. Another was the amount of ability and experience which it secured for the public service. We have called the administrators of public affairs a bureaucracy, and the household of the emperor, but they were not the less a body of most highly trained officials, thoroughly organized in their various services. Each department of the state formed a profession of itself, as completely subdivided, and requiring as special an education, as the legal profession at the present day. This perfection of this machinery accounts for the empire not having fallen to pieces in times of internal dissension, sometimes accompanied by foreign invasion, and the facilities it afforded for developing talent are seen in the long succession of able administrators which the system produced, and which came to an end at the commencement of the 11th century, when it began to be disused. And besides this, though the rigorously oppressive taxation was injudicious as well as iniquitous, yet it may be doubted whether any other system than the high-handed centralization which has been described could have prevented dissolution. Its force is certainly proved by its vitality, and the first great dismemberment in particular was brought about, not by internal causes, but by the power of the Saracens.

The choice of the site of New Rome—which is perhaps the finest position in the world, as it commands the meeting-point of two great seas and two great continents, and rises in seven hills on its triangular promontory between the Propontis and its land-locked harbour the Golden Horn—is an additional proof of the penetration of Constantine, and the event justified his selection, for on numerous occasions nothing else than the impregnability of the seat of government could have saved the empire from destruction. Though the establishment of a new capital was in itself a consummate stroke of genius, yet to some extent it was forced upon the emperor by his conversion to Christianity, for this placed him in direct antagonism to Old Rome, which was still the headquarters of paganism. And whenever might be the feelings of the people, on the part of the administrators themselves the prepossessions to be overcome in deciding on such a change were less than might be supposed, for the government, absorbed as it was in the unceasing care of maintaining and defending the empire, had long ceased to be Roman in its sympathies, and had become cosmopolitan. The new city at the time of its foundation was Roman, its senators were transported thither from Rome, the language of the court was Latin, and the condition of the lower classes was assimilated to that of the old capital by their being exempted from taxation and supported by distributions of grain. But from the first it was destined to become Greek, for the Greeks, who now began to call themselves Romans, an appellation which they have ever since retained, held fast to their language, manners, and prejudices, while they availed themselves to the full of their rights as Roman citizens. Hence, in Justinian's time, we find all the highest

offices in the hands of Greeks—not Hellenic Greeks, but a Greek Roman caste, the descendants of the Macedonian conquests of Asia, and Greek was the prevailing language. The turning point in this respect was the migration of the East and West in the time of Arcadius and Honorius. Still the Roman system remained permanent, especially in the community of interest created between the emperor and the populace by the largesses and the expenditure on public amusements, the money for which was drawn from the provinces, and this fact explains the antagonism that remained between the provincials and the inhabitants of the capital, and the toleration which the latter showed of the tyranny of their rulers. How deeply these abuses were rooted in the city of Constantinople is shown by the circumstance that Heraclius, in despite of otherwise carrying out his schemes of retrenchment and reform, conceived the design of removing the seat of government to Carthage—a plan which he would have carried out had he not been prevented by the unanimous opposition of the Greeks.

Whether the conversion of Constantine to Christianity was due to sincere belief or to policy, or, as is perhaps most likely, to a combination of the two motives, there can be no doubt that religion had before that time obtained a great influence over the Greeks, and that the cause of the Christian Church and that of the Greek nation were already closely interwoven. Nothing could show more clearly the mastery obtained by the new faith than the subsequent failure of the emperor Julian to revive paganism. We have already seen how life and energy were restored to Greek society by this influence before the end of the 3d century, it was also the unanimity with which it was adopted by that people which inspired them to combine in self defence, and saved them from the fate of the disunited Western empire. From that early period dates the feeling of brotherhood which pervaded the Greek Church, and the strong attachment which has always existed between the Greek clergy and their flocks, further cemented as it was at a later period by the influence which the clergy exercised in maintaining the people's rights and defending them against aggression. Paganism, however, continued to be recognized until the time of Theodosius the Great, when Christianity was substituted for it by legislative enactments. But the orthodoxy of the Eastern Church, which came to be, and still is, its most distinctive feature, and the identification of the Orthodox Church with the Greek nation, dates from a different time, viz., from the reigns of the Arian successors of Constantine, to whose personal opinions the people were strongly opposed. The political effect of this union ultimately became very great, and resulted in the loss of important provinces to the empire. When the Orthodox had the upper hand, they soon began to clamour for the persecution of heretics, and the emperors being on the same side acceded to their demand. The natural effect of this was disaffection in those regions, such as Syria and Egypt, where the majority of the population were either Nestorians or Eutychians, and the evil was aggravated by the suspicion to which the provincial clergy were exposed, because they were not Greeks, of being heretodox. The alienation from the central government thus produced greatly facilitated the conquest of those countries by the Saracens. It should also be noted that from the time of Constantine the emperors claimed, and were acknowledged, to be supreme over the church in all civil and external matters—a power which, as we shall see, proved to be of great importance at the time of the monastic controversy, and the extensive judicial and administrative authority which Theodosius conferred on the bishops was the origin of that political subservience, and at the same time of those monastic practices, which have been the opprobrium of their order in the Eastern Church.

Reign of
Justinian

The reign of Justinian, which, from the important events which it contained, has actually much attracted the notice of historians, was a period of false brilliancy. The character of that emperor in many respects resembles that of Louis XIV. Both were men of moderate ability, gifted with great industry and application to business, and with a remarkable power of employing the talents of others, both were fond of splendour and foreign conquest, and both impoverished and ruined their subjects. At the time of his accession Justinian found in the exchequer a large sum of money amassed by Anastasius I., and had he employed this in lightening taxation and improving the position of his subjects, instead of wasting it in wars of his own seeking and lavish expenditure on public buildings, he would have greatly strengthened his kingdom. No doubt the conquests of his generals were splendid, and testify to the greatness of the armies of the empire at this time. No doubt also the compilation of the *Pandectæ, Code, and Institutes* was a magnificent work, which has left indelible traces on the legal systems of Europe. And it is an honour to any age to have developed the Byzantine style of architecture, a style thoroughly Greek in its unity and proportion, for, whereas the Romans had borrowed the ancient Greek style, and, adding to it the arch, had used it for wholly incongruous purposes, the Greeks in turn appropriated the arch and dome, and created a new and harmonious style. But the effects of his reign on his dominions were ruinous. He retorted tighter the fetters which Constantine had invented, but he lacked the penetration of Constantine in perceiving the needs of his time. He dissolved the provincial militia, which to some extent still existed in Greece. The population were ground down by taxation, the revenues of the free cities in Greece were seized, and at last the fortifications fell into disrepair, and a great part of the army was disbanded, so that when Zobeig, king of the Kutigur Huns, invaded the country from the north in the year 550, he was able to approach within 17 miles of Constantinople. How great the demoralization was is shown by the state of the empire under Justinian's immediate successors. Within less than twenty years after his death the convulsion of a great change impending was so widely spread that a story was rife that it was revealed to the emperor Theodosius II. in a dream that on account of his virtues the days of anarchy should not commence during his reign. The condition of things has been described as "universal political decay."

Barbarian
invasions

The 400 years which elapsed between Constantine and Leo III. were the great period of the barbarian invasions. The Goths, who, as we have seen, had overrun Greece in the latter half of the 3d century after their great defeat at Naissus (Nisch), were more or less kept in check, and became in some degree a civilized and Christian people in the country of Dacia, to the north of the Danube, which they had permanently occupied after the Roman colonies in that country were withdrawn by Aurelian. But in the reign of Valens, when the Huns were overrunning Europe, they were pressed onwards by those invaders, and occupied Mesia between the Danube and the Balkan, which province was peacefully ceded to them. It was only in consequence of treacherous treatment by the Romans that they afterwards entered the empire as enemies, and fought the campaign which ended in the defeat and death of that emperor (378). They were again checked by Theodosius, and persuaded to enlist in great numbers in the imperial service, but during the reign of his successor Arcadius, the famous Alaric, who was the spirit of his countrymen, and ravaged the whole of Greece even to the Peloponnese (395), before he turned his thoughts to the invasion of Italy. For a time both Goths and Romans were the victims of Attila, who with

his hordes of Huns swept over the lands south of the Danube (452-7), and was only induced to retire by an agreement on the part of Theodosius II. to pay him an annual tribute. But again, in the reign of Zeno (475), the empire was in imminent danger from the Goths under Theodoric, who, like Alaric, had lived at Constantinople, and like him also withdrew into Italy. Towards the beginning of the 6th century the Goths made way for more barbarous invaders, Bulgarians of Thracian origin, and various Slavonic tribes, for whose pastoral habits the now depopulated country was better suited than for a more civilized population. But they in turn were soon swallowed up by the Avars, whose vast monarchy occupied a great part of eastern Europe, and whose armies, in the time of Heraclius, threatened Constantinople itself. It was in order to impose a permanent check on that people that this emperor induced the Sarmians and Croathians to occupy the districts eastward of the Adriatic, Dalmatia and Illyricum, which were deserted, owing to their constant incursions. These Slavonic settlers paid allegiance to the empire, and as they formed agricultural communities, introduced an element of permanence into the country. The Avar power disappeared as suddenly as it had risen, and at the end of the 7th century its place is taken by the Bulgarian kingdom, which lasted for nearly 850 years, and was the great antagonist of the Byzantine empire in its most flourishing period. At the close of this long series of invasions, we cannot help being astonished at the successful resistance that was offered to them. No doubt the conformation of the European provinces of the Eastern empire, with their successive mountain barriers, was a source of strength from the ease with which they could be defended, but this could hardly have saved the Greeks, had it not been for the number of their walled cities, their superiority in the art of war, the courage of the people when called out by circumstances, and the strong position of the capital.

On the side of Asia, during the same period, a long Persian struggle was maintained with Persia. The dynasty of the Sassanides, which arose on the ruins of the old Parthian kingdom, had raised that country to great power and prosperity. The second in order of its princes, Sapor I., had taken the emperor Valerian prisoner (257), and a century later Julian lost his life when fighting in Persia. The ill success of Justinian in his Persian war was ought fairly to be ascribed as much to the ability of his great opponent, Chosroes Nushirvan, as to his own shortcomings, but the fact remains that even Belshazzar won small glory from those contests, and after a struggle of twenty years' duration a treaty was concluded, which required the European monarch to pay an annual subsidy of thirty thousand pieces of gold. War, however, continued during the reigns of his successors Justin II. and Theodosius II., until an honourable peace was concluded by Maurice, the son-in-law of the last named emperor, at whose court Chosroes II., the ungrateful sovereign, had been received when he was an exile. Thus prince, when he was reinstated on his paternal throne, showed his gratitude to the Romans. But when Maurice was dethroned by the rebel Phocas, the Persian monarch declared war, professedly with the design of avenging his benefactor. The greater part of the Asiatic provinces were laid waste, and a Persian army was for a time encamped on the shores of the Bosporus, so that it seemed as if the Roman empire was about to be conquered by Persia. From this it was saved by Heraclius, who was not only one of the ablest of the emperors, but one of the greatest of military leaders. He ward off the impending danger, and in seven campaigns, by a series of brilliant victories, dealt a death-blow to the Persian power. The struggle was unavoidable, and Heraclius, in entering upon it, was actuated by no vain desire of military renown, but the effects of it were disas-

tion to the Romans also. The period when it occurred was that of the rise of the Sassanians, and the exhaustion caused by it contributed in no slight degree to the extension of their power.

Condi-
tion of
the popu-
lation

We turn now to the condition of the Greeks during this period. In the interval between the first Gothic invasions and the accession of Constantine the material property of Greece had increased, owing partly to the devastation of the provinces to the north of that country, the wealthy inhabitants of which were forced to take refuge in Greece, and partly to the insecurity of the Red Sea, Egypt, and Syria, which caused the commerce of Central Asia to take the route of the Black Sea, whence the trade of the Mediterranean passed once more into the hands of the Greeks. It can hardly be said that the reforms of Constantine benefited the population, because of the severe exactions they introduced, for, as has been already mentioned, the rich were forced to supply from their own incomes any deficiency that might occur in their district, and by this means, before Justinian's time, the class of great landed proprietors had been extinguished. But the fixed position which the clergy and the lawyers obtained under Constantine's system was a general advantage, because this constitutional check modified the oppressiveness of the Government in its dealings with the people. In the case of the latter of these two orders the effect would have been greater, had not Latin been the language of legal business until after the time of Justinian. The period of 130 years between the death of Arcadius and that emperor's accession was a time of improvement. During the long reign of Theodosius II the power was in the hands of his sister, the philanthropic Pulcheria, and of his ministers, and these seem to have ruled judiciously, and the five succeeding emperors, Marcian, Leo I, Zeno the Isaurian, Anastasius, and Justin, who all men born in the middle or lower class of society, and of provincial origin, and had come to the throne at a mature age. The sympathy which they thus had with the body of their subjects accounts for their economy, and for their endeavours to restore the resources of the empire and alleviate its burdens, and generally to introduce regular forms of procedure into public business. Far different was the case with Justinian, whose severe demands for money distressed all classes of his subjects.

Athens

But it was on Athens that his hand was most heavily laid. That city was still a literary capital where Hellenic learning was cultivated, and if the *Hero and Leander* of Musæus and that graceful pastoral romance, the *Daphnis and Chloe* of Longus, are to be assigned to so late a date as the fifth century, the spirit of the ancient Hellenism had not long been extinct among the Greeks. The ancient buildings still existed in all their splendour, the citizens lived a life of quiet, self-complacent ease, and the paganism, of which it was now the centre, had been purified from its vices by the maxims of philosophy and the influence of Christianity. It remained for Justinian, in his merciless centralization, to close its schools and confiscate their revenues. At the same time the Olympian games were brought to an end. From this time onward the inhabitants of Hellas are but little heard of, and at the beginning of the 8th century we find them spoken of by Byzantine writers under the contemptuous title of Hellenoi, while the Greek nation is represented by the population of Constantinople and Asia Minor. Yet this period was not wholly disadvantageous to Greece. As the danger from the invading barbarians increased, its citizens regained the power of using arms, and revived a municipal administration to direct their efforts. It was also in Justinian's reign that silkworms were introduced from China, and the manufacture of silk became a profitable source of revenue to Thebes and other towns.

One result of the financial legislation of this time was a change which, though the lawgivers certainly did not foresee

it, was most beneficial in its effects. This was the gradual extinction of slavery in the Eastern empire. The position of that class which this was not Christianity, for it is religion had recovered slavery as an institution, not yet civilization, for that among the Greeks was intimately connected with the employment of slaves. It was rather produced by an alteration that was taking place in the condition of certain classes, which annihilated the distinction between the free-man and the slave. When the oppressiveness of taxation had destroyed the wealthy proprietors, and in order to prevent the land from falling out of cultivation and thus diminishing the revenue, the cultivators of the land were tied to the soil, the poorer class of freemen began to sink down into the condition of serfs. On the other hand the slaves who were employed in agriculture became for the same reason an object of solicitude to the legislature, and their proprietors were forbidden to alienate them. They thus acquired a recognized position, not far removed from serfdom, and when all the lower class were reduced to the same state of poverty, the difference in the political status of the two orders came to be obliterated. Many centuries elapsed before this change fully worked itself out. The slave trade was still an important branch of commerce in the Roman empire, and freemen were sold as slaves if they failed to pay their taxes, but henceforth the system was doomed to ultimate extinction. When we consider the extent to which slavery prevailed in the ancient world, and the misery which it caused, we cannot regret the circumstances which caused it to disappear, even though they were accompanied by much suffering.

It is important also to remark, now that we are approaching the period of change from ancient to modern society, that the decline of civilization in the later Roman empire was not owing to degeneration in the people themselves, or to an inevitable downward tendency in highly civilized communities. It is a mistake to attribute decay in human character changes that are clearly traceable to the need of such external resources as are indispensable for its development. The prohibition to carry arms necessarily renders a people unwarlike. Where municipal institutions are discouraged, public opinion soon becomes powerless. When the resources which might be employed in constructing roads are withdrawn, communication ceases, and with it the interchange of ideas and other influences by which the intellect is quickened. The degradation was produced by the iniquity of the Government, which degraded its subjects, and systematically destroyed independence among them. Whenever the iron hand was removed, they showed signs of renewed life and vigour, but the strength of the central power was too great to encourage any hope of resisting it successfully. They had no choice but to eat down under it, and suffer it to drain their life-blood by slow degrees.

At the commencement of the 8th century the extinction of the empire of the East appeared to be imminent. The same causes which had overthrown the Western empire were threatening it with destruction. The Sassanians had overrun all its Asiatic possessions, and had attacked the capital itself, while in Europe it was threatened by the Bulgarians. The provinces were falling off Syria, Egypt, Africa, and the conquered provinces of Spain were wholly lost, and in Italy the dominions of the exarchate were greatly circumscribed by the Lombards. At home rebellion prevailed in the army, and anarchy in the government, six emperors having been dethroned within the space of twenty-one years. It seemed as if the Greek race itself would be destroyed, in the countries conquered by the Sassanians the Greeks were almost exterminated, and Greek civilization proscribed, while Hellas was threatened with occupation by the barbarians. But at this moment the helm of the state was

served by a man who, by his force of character and his great abilities, inaugurated a new state of things, and gave the empire a new lease of life. This man was Leo the Isaurian.

III. *Period of Byzantine Prosperity from Leo III to Justin I (Commence), 716-1057 A.D.*

The By-
zantine
empire

Considerable difficulties of opinion have existed as to the precise time at which the Roman empire of the east may be said to have ended, and the Byzantine empire to have commenced. Gibbon remarks that "Thebans by the Arabs, and Maurice by the Italians, are distinguished as the first of the Greek Cæsars, as the founders of a new dynasty and a new order of things, and the introduction of the old Roman system of administration, and the introduction of the state." These commenced, no doubt, shortly after the death of Heraclius, and were closely connected with the victorious advance of the Saracens, which necessitated a reform, and at the same time concentrated the empire, and confined it more and more within the districts inhabited by Greeks. But the oldest state of things did not become apparent, nor were the changes systematized, until the time of Leo III, and therefore he may most rightly be regarded as having inaugurated the Byzantine empire. The first century and a half of the present period embraces the iconoclastic controversy, while the two remaining centuries coincide with the rule of the Basilian dynasty. It was a time of great men and great achievements, both in government and war, and the events it contains amply suffice to defend the Byzantine empire from the imputation of feebleness and decrepitude, and those who delight to find in history strongly marked characters and stirring incidents will be amply rewarded here. Few personages stand out in stronger relief than the ruthless, yet ascetic, warrior Basil, the slayer of the Bulgarians, and few occurrences are more romantic than the death of Leo the Armenian, who defended himself with the crucifix in his chapel, where he was chanting the prayers in the early morning, while his successor lies in fetters in the neighbouring dungeon.

Reforms
of Leo
III

We must first notice the reforms, which caused the reign of Leo III to be an era in the history of the empire. These extended to almost every branch of the administration. In respect of the army, he reorganized the military establishment by placing the various bodies of soldiers in the different "themes," or deputy themes, each with a general of its own, thereby providing for local defence, and avoiding the danger of rendering the military commanders too influential—a system which defended the empire for five centuries. The geographical arrangement in theme was also introduced by Heraclius, but reorganized by Leo, and bore somewhat the same relation to the previous division into provinces that the departments in France bear to the earlier distribution of that country. In respect of finance, he brought the taxation immediately under the emperor's cognizance, so that thenceforth the emperors were their own finance ministers. All local agencies for collecting the taxes were abolished, and their functions transferred to the imperial officers, who took census regularly. By this means he raised more money than his predecessors, but the increased prosperity of the people showed that the burden did not fall so heavily. In respect of justice, in order to obviate the difficulties which had arisen in the administration of Justinian's elaborate laws, especially since the facilities for communication throughout the empire had decreased, he published in Greek an abridged manual called the *Beclog*, and codified the military, agricultural, and maritime laws. In respect of religion, he aimed at counteracting the element of superstition which had crept into the church, and through it was corrupting the public mind. But this last

point calls for separate consideration, since the worship or prohibition of images became the burning question of the age.

The history of iconoclasm is the history of Constantinople Iconoclasts during the 8th century and the first half of the 9th, and claim involved a great part of the empire in its distractions. There can be little doubt that, in his opposition to image worship, Leo represented the opinion of a large part of the enlightened laymen of his time, while the great body of the clergy, but especially the monks, together with the mass of the population, were passionately attached to the statues and pictures, as objects of veneration, not to that of adoration. But the fact that the stronghold of iconoclasm was Asia Minor, and especially that part of it which had been on the countries occupied by the Saracens, suggests that it was in part owing to the spread of Mahometanism, the rigidly guarded spirituality of which creed was a standing protest against more material conceptions of religion. Nor should we overlook the deeply rooted feeling in the mind of Orientals of the opposition between spirit and matter, which would naturally cause them to be alive to such questions of controversy. The emperors of this time were those of the Isaurian, Armenian, and Amorrian dynasties, all which names remind us that they came from the Asiatic provinces, whereas the great majority of the emperors since the emperor Irene, during whose reign the second council of Nicaea in their favour was held (787 A.D.), was an Athenian. But the matter was complicated by a further issue, the question of images was closely connected in the minds of the emperors, and especially of Leo III and his hard-handed son Constantine Copronymus, with that of their supremacy in matters of religion. They viewed with jealousy the independent power of the church, and were glad of the opportunity this controversy afforded of strengthening their control over this department, and claiming to the full those ecclesiastical rights which, from the time of Constantine the Great onward, had attached to the imperial authority. As this move was only part of a system of centralization, the monks and others who supported image worship were from one point of view the assents of liberty against aggression, and they were recognized as such by a certain number of thinking men, who watched with anxiety the growth of despotism. As toleration was unknown to the age, persecution was carried on by both sides with equal fierceness, and the contest swayed to and fro, until it was brought to an end by the final restoration of images under Michael III, the last of the Amorrian line (842). Its effects on society had been remarkable. At first its influence was bracing, as was shown by the renewed vigour which pervaded the empire, for both sides were thoroughly in earnest, and among the iconoclasts in particular an element of Prussian energy was evolved. But in its later stages, when the people at large were weary of the strife, and the struggle was felt to be in reality one between church and state, the prevalent hypocrisy generated disrespect for religion, and this was followed by general immorality. It further caused the loss to the empire of its dominions in central Italy. So great was the alienation produced by this movement in the minds of the popes Gregory II and III that thenceforward the holy see was for the most part either active in its opposition to the Byzantine power or lukewarm in support of it. At last, in 761, Ravenna was captured by the Lombards, and the Greek exarch retired to Naples.

The subsequent ecclesiastical affairs of this period must be briefly dismissed, though they exercised an important influence on the fortunes of the Greeks. The final separation of the Eastern and Western Churches took place in 1053, though events had long before been leading up to it. Already in the middle of the 9th century, when the pope

Since
quest
ecclesi-
natural
affairs

antagonism between the rival patriarchs Ignatius and Photius, a rupture was very nearly occurring, and at last, though the formal causes of division were theological, yet the assumptions of the see of Rome and political antagonisms were in reality more influential motives. The bitterness thus created culminated in the capture of Constantinople by the Latins at the time of the fourth crusade, and the subsequent refusal of aid by the Western nations to the Greeks greatly facilitated the success of the Ottomans. From this, the greatest breach in the Christian world, we turn with thankfulness to the missionary efforts of this age. In the middle of the 9th century two brothers, Cyril and Methodius, preached the gospel to the southern Slavonians, and converted them to Christianity. By Cyril the alphabet called Cyrillic was invented, which was generally adopted by the Slavonic peoples. About the same time the Bulgarians renounced their paganism, through the influence of a sister of their king, Bogoris, who had been educated as a prisoner at Constantinople, and afterwards restored to her native country. The rest of the nation had been prepared for this change by the numerous Christian slaves who had previously been carried off by them in war. A century later Christianity was introduced by Greek influence among the Russians, whose capital was now at Kieff, and who were among the most dreaded foes of the Eastern empire. If the missionary spirit is the best evidence of the vitality of a church, it is clear that at Constantinople, however much corrupted by formalism, was still animated by the spirit of true religion.

The Persian monarchy, which for 400 years had been the rival of the Roman power in Asia, had now succumbed to the victorious arms of the Saracens, and that people again, during the next four centuries, were engaged in almost continual war with the Byzantine empire. In the reign of Constantine Pogonatus, the caliph Mosowrah besieged Constantinople for seven years by land and sea, the invaders coming to Cyzicus for the winter (672-3), but, owing in great measure to the newly invented Greek fire, he was obliged at last to desist from the attempt, and almost the whole of his force was destroyed. Notwithstanding this reverse, the attempt was renewed within a year after Leo III's accession by Melemaeh, brother of the caliph Suleiman, with an enormous host, but the skill of the Byzantines in military defence, which was equal to that of the Romans in their best days, baffled his attempts, and a winter of extraordinary severity ensuing ruined the attacking army. The importance of this result was incalculable to Europe—far greater than that of the victory of Charles Martel at Tours. The Saracen empire was now at its height, and reached from the Indus to the Atlantic, and it was the full height of this power, now in full tide of conquest, which was resisted at Constantinople. Had that city fallen, there was no power that could have prevented it from overrunning Europe. After this, Asia Minor continued for ages to be the battle-ground of the two opposing empires, until it was so devastated and depopulated by successive campaigns as to be fit only for the occupation of the nomad tribes who were to succeed. In the midst of these struggles the invasions of Haroun al Rashid, the splendour of whose court obtained for him a reputation in the West which he did not enjoy among his contemporaries in the East, appear hardly more than plundering incursions. The Byzantine nobles, who were trained in this school of war, were distinguished for their military spirit and personal powers, and the troops of which the armies were composed were so powerful and well-disciplined that the Saracens would never meet them in the field except with far superior numbers. By sea, however, the empire was less successful than by land. During the first half of the 9th century both Crete and Sicily were conquered by these enemies, and in

the year 904 occurred the memorable sack of Thessalonica. A Saracen fleet appeared before that city, and, after storming the sea-wall, pillaged the whole place and butchered the citizens without respect of sex or age. The most famous successes were those of Nicephorus Phocas and his successor John Zimisces. The former of these great commanders, who before he became emperor had reconquered the island of Crete, at the end of a brilliant campaign in 971 obtained possession of Antioch (968) after it had been in the hands of the Mahometans for 328 years. Five years later Zimisces carried his victorious arms even to the banks of the Tigris. But while the disorganized state of the caliphate of Baghdad, in the early part of the 11th century, removed all fears from that quarter, a new enemy began to appear on the eastern frontier of the empire—the Seljuk Turks. Unfortunately, at this critical conjuncture, a fatal mistake was made. The safety of that frontier had long been guaranteed by the Armenian kingdom of the Bagratians, whose country was admirably adapted for defence, and whose population were a hardy race of Christian mountaineers. In the year 1045 the emperor Constantine IX. destroyed this kingdom, and thereby laid his dominions open to the invaders.

In Europe, at the same time, the empire was exposed to Bulgarian attacks of a foe hardly less formidable, and in closer proximity—the Bulgarians. After the extinction of the Avars, the people, who had long been in subjection to them, had founded an important monarchy in the ancient Maritima at the end of the 7th century, and henceforward the Byzantines had to defend their European possessions, not as before against a succession of migratory tribes, but against the concentrated force of a single nation. In the time of Constantine Copronymus we find that it required all the energy and military talents of that emperor to keep them at bay, and on one occasion they carried their ravages up to the neighbourhood of the capital. In the beginning of the 9th century their king, Omurtag, defeated and slew the emperor Nicephorus I., who had invaded his territory, in a night attack on his camp, and converted his skull into a drinking-cup for his table. We have already noticed how, later in that century, the nation embraced Christianity, and at the same time a tract of country on the southern side of the Balkan range was ceded to them, and received from them the name of Zagora. By this time also they had imperceptibly changed their nationality and their language, for by intermingling with the more numerous Slavonic tribes of the countries in which they settled, they lost the traces of their Hunnish origin, and became to all intents and purposes a Slavonic race. By the neighbourhood of Constantinople, and the trade between that city and the German and Scandinavian peoples which passed through their country, they became a commercial nation, and advanced in the arts of life. But the rapacity of the Greeks in imposing heavy customs on their traders involved them again in war with the empire, and when peace was re-established, the treaty between Romanus I. and their king, Simeon, was made under the very walls of Constantinople (928). In the reign of Nicephorus Phocas the Russians, who had not long before appeared on the scene of action, were invited by the Greeks to invade Bulgaria, and they so effectually crushed the Bulgarians (968) that his successor, John Zimisces, was obliged to come to their aid, in order to save his own territory from falling a prey to the new comers. It was shortly after this that the great and final struggle commenced. Under their chief, a cruel, a mad, a godless tyrant, they extended their conquests over Macedonia and Thessaly, and made plundering incursions into Greece and the Peloponnese. But finding that the plains of Bulgaria were unfavourable to him as a seat of war, on account of the superior discipline of the imperial

forces, Samuel transferred his seat of government to Achrida, on the confines of Macedonia and Albania, and thence he extended his kingdom from the Adriatic to the Aegean, so that the country he ruled was as extensive as the European portion of the Byzantine empire. But these events coincided with the culminating period of Byzantine greatness, and Samuel found a worthy rival in Basil II, who from his subsequent victories obtained the title of "Slayer of the Bulgarians." By him the Bulgarian power was brought to an end, and the whole people submitted to the domination of the Greeks (1018).

The Ross
at 1094

The third people with whom the empire had to contend at this time was the Russians. In the reign of Michael III, the last of the Amorin dynasty (865), the inhabitants of Constantinople were astonished by the appearance in the neighbourhood of the city of a fleet of 300 small vessels, which passed down the Dosphorus from the Black Sea. The enemy contained in these was the Russians, who not long before had established themselves at Kieff on the Dniester, and whose restless spirit and love of plunder prompted them to attack the strongest city in the world. Their ignorance of the art of war rendered them no formidable foe to the Byzantine forces, but their daring and cruelty produced a profound impression on the civilized and peaceful citizens. Similar attacks were made in 907 by Oleg and in 941 by Igor, but the influence of trade and the introduction of Christianity into Russia gradually promoted more peaceful relations, and the Byzantines employed the powerful tribe of the Patziaks, who occupied the northern shores of the Black Sea, to counterbalance their opponents. But the campaign of John Zimisces on the Danube in 971, which followed on the negotiations of his predecessor for the subjugation of the Bulgarians, showed how important a military power the Russians had become, for he found in their chief, Svatoslav, an enterprising and powerful adversary, whom it required all his skill to overcome. Once more, in the time of Constantine IX. (1045), the Scandinavian Varangians, by whom the Russians were mostly represented in their marauding expeditions, appeared before Constantinople, but with no better success than before, and from this period the alliance of that people with the Byzantines was long uninterrupted, and the two nations were bound together more and more by religious sympathy. In the days of the Comneni the Varangians regularly formed the bodyguard of the emperor.

Constantinople
changes

Constitutional changes were usually of slow growth in the Byzantine empire, yet at the end of this period we find considerable alterations to have been effected. Under the early iconoclastic emperors there was a tendency towards the greater concentration of power in the hands of the sovereign, but Basil I. converted the government into a pure autocracy or despotism. This he effected by abolishing the legislative functions of the senate, which body, though now a shadow of its former self, had existed in one form or another all along, and exercised a certain influence in controlling the absolute power of the emperor. When this restraint was removed, and the senate reduced to an administrative council, no further check remained except the fear of revolution. Basil also tacitly introduced what, strange to say, had never existed in the Roman empire, and even now was only partially recognized—the principle of legitimacy in succession. With a view to this he established the custom that his descendants should be born in the "porphyry chamber," so that the name Porphyrogenitus might become a title of legitimacy. In this way a partial antidote was created to that inveterate disease of the Byzantine empire which a French writer has called *la maladie du trône*—the ambition to be emperor at all hazards, notwithstanding the risks involved both in the attempt and the possession of the office. The growth of the idea is proved by the loyalty

shown a century and a half later to the empress Zoe, an aged, ugly, and incapable woman, on account of the legitimacy of her descent. But the greatest change of all, and one that contributed greatly to the subsequent decline of the empire, was effected at the end of this period. This was the abolition of the system of naming officials to conduct the various departments of the state, and the entrusting those offices to eunuchs of the imperial household. The object of this was to lessen the power of the territorial aristocracy, and to diminish the chance of rebellion, by placing the government in the hands of men who could not found a dynasty, but from the time onward the efficiency of the administration began to wane. It was the disorganizing of the aristocracy involved in this change that caused the conspiracy of the nobles in Asia Minor which set Isaac Comnenus on the throne. It should also be noticed that few of the emperors throughout this period were Greeks, most of them being either Armenian or Slavonian by extraction. This circumstance accounts for a certain freedom from prejudice and independence of view which may be traced in their actions, but at the same time it caused them to be wanting in sympathy with their subjects.

During a considerable part of this period, notwithstanding the desolating wars which we have described, the prosperity of the inhabitants of the empire was very great. Emly, who is excellently qualified to judge of the state of this kind, gives it as his opinion that under the iconoclastic emperors the moral condition was superior, not only to that of all contemporary kingdoms, but to that of any equal number of the human race in any preceding period. The society of this time has been too much judged of by the misdeeds and mutilations which were a life in consequence of the struggles for the throne, but it should be remembered that these were confined almost entirely to the court and its surroundings, and did not affect the mass of the people. And then material prosperity was equally great. The emperors Theophilus, notwithstanding his lavish expenditure, is recorded to have left at his death a sum equal to five million sovereigns—an amount of money which could hardly have been extorted from a people otherwise than wealthy. This was the result of the commerce of their immense maritime empire, which had in its hands the whole of the carrying trade between Asia and western Europe. To this it should be added that, under Basil the Macedonian and his successors, care was taken to moderate the burden of taxation, a policy that accounts in great measure for the duration of his dynasty, which occupied the throne of Constantinople longer than any other. Unfortunately the riches thus obtained tended after a time to accumulate in the hands of the few, and from the reign of Basil II the middle class, that element which society can least of all afford to dispense with, began rapidly to diminish. As a consequence of this, in the 11th century manufactures declined in the cities, while in the country the immense estates of the aristocracy were cultivated by Mahometan slaves or Slavonian serfs, and this higher class itself began to feel the lethargy of wealth, and though still unconscious of coming change, was on the eve of impending decline.

In the year 1117, during the reign of Constantine IX. Copronymus, the empire was visited by a fearful pestilence, which, both in the mortality and the demoralization of society it produced, must have rivalled, to judge by the accounts left us by the Byzantine historians, those of Florence and London, of which Boccaccio and Defoe have drawn such vivid pictures. As this calamity was the primary cause of the immigration of foreign settlers into Greece, it is intimately connected with the question of modern Greek nationality, and consequently the present appears a fitting place briefly to discuss this subject, on which great differences of opinion, turning mainly on the

Condition of
the people

Modern
Greek
history

medieval history of the country, have prevailed. The controversy originated in the famous thesis, of Professor Pallmeyer of Munich, that, owing to the great influx first of Slavonian and afterwards of Albanian colonists, not a single drop of Hellenic blood flows in the veins of the Greeks at the present day. The discussion of this point has enlisted much ability and learning on both sides, but the question appears now to have been pretty well settled by the abandonment of Pallmeyer's hypothesis. How early barbarian settlements began to take place in Greece it is difficult to determine, but though the occupation of the Peloponnese by Avars and Slavonians at the end of the 6th century, on which much stress has been laid, is doubtfully historical, yet colonies of those races probably established themselves in the northern part of Greece. But that the great change in this respect was produced by the pestilence is shown by the obliteration of Hellenic names of places which dates from that time. For, though a fair number of ancient names of seaport towns, such as Pathe, Corinth, and Epidaurus, and some names even in a district so extensively occupied by Slavonians as Attica, have been preserved to the present day, yet the great majority of the modern names are now, and have been since the 8th century, either Slavonic or of late Greek origin. Not only was the country greatly depopulated by the plague, but a considerable portion of the native middle class was induced by the emperor to migrate to the capital, in order to fill up the void in the inhabitants which had been caused by the ravages. The districts which were thus left vacant were soon after occupied by Slavonian tribes, so that until the middle of the 9th century they formed a large part of the population. But in the latter part of that century the Greeks began to recover a numerical superiority, and from this period dates the process of the absorption and Hellenizing of the Slavonians, so as to form the mixed race of which the greater part of the population of Greece is now composed. In effecting this change the Greek Church played an important part. The affinity between the ancient and modern Greeks has been traced by several lines of reasoning. It has been pointed out how great is the resemblance of character between them, and that too in points presenting the sharpest contrast to the character of the Slavonic races. The survival of old beliefs and classical superstitions at the present day has been carefully observed. The language is a direct descendant of the ancient speech, and contains next to no Slavonic element, and last it should be thought that this language had been imported into the provinces from one or more great centres, and had not survived in the districts themselves, it is proved that numerous classical words and forms, which have been lost to the language at large, still survive in the local dialects. Thus, though the physical connexion between the modern Greeks and the ancient Hellenes, in certain districts at all events, may be slight, as seems to be implied by the difference of physiognomy, yet in all that really constitutes a people, their character, feelings, and ideas, the former are the direct descendants of the latter.

IV *Period of Byzantine Decline from Isaac I to the taking of Constantinople by the Latins, 1081-1204 A.D.*

The
Commen-
tary

At the commencement of the preceding period there was a prevailing fear among the inhabitants of the empire that its extinction was imminent, and we have seen how this was followed by an age of unexampled prosperity. The feeling of the time on which we now enter was completely the opposite of this, and yet it was a period of decline. The long duration of the empire, notwithstanding numerous vicissitudes, its superiority to contemporary nations in power and wealth, and its apparent security from foreign

enemies, inspired the people with a belief in its permanency, and blinded them to the seeds of decay that were already working. Yet before the end of the 11th century the Seljuk Turk had occupied all the inland part of Asia Minor, and had established there his capital at Nicæa, in the immediate neighbourhood of Constantinople. It would, however, be a mistake to suppose that, in its external relations at all events, the whole of the Comnenian period was a time of decay. On the contrary, during a considerable period it witnessed a remarkable revival, and the three great emperors of that dynasty, Alexius, John, and Manuel Comnenus, whose long reigns extended over an entire century (1081-1180), were men who would be conspicuous figures in any age. All of them were distinguished by personal courage and skill in war, by literary culture, and by sagacity in politics, but in other respects they represented very different types. The first, Alexius, was indefatigable in business, patient in maturing his schemes, and active in carrying them out, but vanguardic, unprincipled, and fond of artifice. From this Ulyssesian phase of Greek character we turn to a true Achilles, his son John, the most amiable character that ever occupied the Byzantine throne—a man inaccessible in morals, open-hearted, generous in action, prudent in council, and pious without superstition. The last of the three, Manuel, presents us with a nature spoiled by the early possession of absolute power, but gifted with most of the virtues admired by his contemporaries—handsome in person, tall of stature, and so powerful that, at a tournament at Antioch in which the chivalry of the West took part, he unhorsed every antagonist—but passionate in temper and ill-regulated in mind. In an age which produced men like these it may well be inquired, What were the sources of decline?

In the first place, the emperors were almost the only capable men. This was the natural effect of the centralization of the system. The neglect of the education of persons intended to be employed in the administration, and the employment of eunuchs of the court for offices of trust, were now bearing their fruit. Everything depended on the existing sovereign, and it only required the view of a thoroughly profligate man like Andronicus Comnenus, the last of his dynasty, to ruin the state. As might be expected also under these circumstances, disorder soon crept into every branch of the public service. The census, which for eleven centuries had been carefully compiled, was now neglected, justice, which more than anything else had united the provinces to the empire, was more imperfectly administered, and the army became inferior to those of Western nations. This last change was produced partly by the degeneracy of the nobles in military spirit, owing to the growth of luxury, partly by the officers being appointed by favouritism, and the habit of disbursing troops at the end of a campaign, in order to save money to defray the expenses of the court. At the same time the great diminution of the middle class, owing to the extension of the large properties, lessened the number of those who were willing to defend their liberties against invaders. The privileges also, in respect of trade, which were conceded by Alexius I. to the Venetians and by Manuel to the Genoese and Pisans, to the detriment of the native merchants, commenced the decline of Greek commerce, and this was accelerated by the piracy that arose, when the money that had been contributed by the commercial communities for the maintenance of local squadrons of galleys was ordered to be retained at Constantinople. To all this must be added the influence of the higher Greek clergy, whose subservience to the state had increased since the separation from the Western Church, and the conservatism of whose ideas discouraged all attempts at progress on the part of the people.

The
crusade

The age of the Crusades is the time of the crusades. These famous expeditions will produce a very different impression on the mind according as they are regarded from the point of view of the East or the West. From the latter point of view they may be regarded as bringing to a focus the religion and united into a sort of the time, a forming a unity which for its intensity, is calving the ideas and cloaking the spirit of the people. But to the great mass of the Eastern they appeared as a badly better than war and an expedition, and is producing unmitigated evil. Though the first crusade (1095) was truly undertaken in consequence of the solicitations of Alexius for aid against the Seljuks, yet it soon is the first undisciplined band, and the enemy they pillaged the natives, and when the most organized companies followed, though many of their leaders, like Godfrey and Tancred, were men of the highest character, yet it required all the address of the Byzantine monarch to turn these armies into Asia without some irreparable injury being done to his capital. No doubt the fanatics were not all on one side, for the suspicion and falsity of Alexius gave just ground of complaint to the crusaders. But he had a very difficult part to play. Had he placed him in, as was proposed, at the head of the crusade, he had no reason to expect obedience on the part of the feudal nobles, while at the same time he left his kingdom exposed to the danger of invasions from home and from abroad. Accordingly he chose the ignominious part, and followed in their footsteps with a view of regaining what he could to his dominions. The second and third of these expeditions proved through the empire with comparatively little injury, though in the latter of the two the island of Cyprus was lost to Richard of England, but the ill-will that was manifested by the Greeks on these occasions ripened in the minds of the Western as those seeds of hatred which at last bore fruit in the great buccannery expedition which is commonly called the fourth crusade (1201). This event, of which a narrative has been left us from both sides, by the Greek historian Nicetas and the Frank chronicler Villehardouin, is certainly one of the most disgraceful transactions in history. A certain lustre has been shed over it by the rage and blindness of the doge Dandolo, who was one of the principal leaders, but that a Christian force assembled for the purpose of fighting the infidels should turn its aim against the most important Christian city of the time is an act of unparalleled baseness, nor can anything be conceived more deliberately mean than the treaty by which the spoil of the empire was partitioned beforehand between the nations who took part in the attack. From this blow Constantinople never recovered, though it is true to add that hardly less injury had been caused by the storm and plunder of the city during the rebellion which set Alexius Comnenus on the throne.

The Sel
juks

In Asia this period opens with a great disaster, the defeat of Romanus IV. by Alp Arslan, in the battle of Manzikert in Armenia (1071). Gibbon has eloquently described the scene, in which the Seljuk sultan, after placing his foot on the neck of the captive emperor, spares his life, and hospitably entertains him. The Seljuk men of Turks were already masters of a great part of western Asia, and in the reign of Malekshah, Alp Arslan's successor, their dominions extended from the banks of the Jaxartes to the Mediterranean. The empire had now entered on the third great struggle of four centuries' duration, which it maintained in the East—first with the Persians, next with the Saracens, and finally with the Turks, whether Seljuk or Ottoman. But the present contest was commenced under altered circumstances. It was soon felt how fatal was the policy which had abandoned the Armenian frontier of its native defenders, and how few obstacles were presented in Asia Minor to an invading force when a large portion of the free

population had disappeared. And the character of the invaders also had changed, for, whereas the Persians and Saracens had felt an interest in civilization, the Turkish hordes were composed of nomad barbarians, whose object in war was plunder, and who occupied the countries they conquered as pastoral tribes. Hence their system of warfare consisted in exterminating the agricultural population by successive incursions, until one district after another lay open for their permanent settlement. Within three years after the battle of Manzikert, the Seljuk power extended over the greater part of Asia Minor, and when, in the year 1080, Nicea fell into their hands, that place became the capital of a separate kingdom, which was called the sultanate of Rum, that is, of Rome. From thence they were driven back by the crusaders at the time of the first crusade, and transferred their seat of government to Iconium, in a more remote position in the south-east of the country. After this they carried on a succession of wars with the Byzantine Government, the most remarkable event in which was the great battle at Myrioccephalus, on the borders of Phrygia, in which the emperor Manuel was signally defeated. During the distractions that prevailed at Constantinople shortly before the fourth crusade, it might have been in the power of the Seljuks to seize that city, and so to anticipate the Latins, but at this time the infidels were divided between the ten sons of the sultan, Kilij-Arslan II, and thenceforward the power of the Seljuks was less formidable.

Meanwhile the European dominions of the emperors had been assailed by a variety of foes, among whom the Normans were the most conspicuous. In the year 1071 Robert Guiscard succeeded in expelling the Byzantines from their remaining possessions in southern Italy, and fired by the ambition of rivaling his great compatriot, who four years and a half before this had made himself master of England, he conceived the design of conquering the Byzantine empire. With the object of carrying this into execution, he laid siege to Dyrrhachium, the most important Greek city on the Adriatic, and after defeating Alexius Comnenus, who had come to its relief, succeeded in making himself master of the place. Being forced to quit the country, he entrusted the campaign to his son Bohemund, who was defeated by the emperor, and withdrew into Italy. Fortune, however, ordained that these chiefs should once more be brought into collision in Syria, and hence arose another Norman war, in which Bohemund was foiled by the strength of Dyrrhachium. At a later period, in the reign of Manuel, Greece was invaded by King Roger, who had received an affront from that emperor, and the cities of Thesalonica and Corinth were sacked in the most barbarous manner. But the most famous of these invasions was in 1185, and resulted in the siege of Thessalonica, which place was taken by the Normans, and treated with a cruelty that almost rivalled that of the Saracens in the former siege. Besides these wars, there were others with the Patinaks, the Hungarians, the Serbians, and the Venetians. But towards the end of this period the empire received a blow from the revolt of a people who on this occasion appear prominently in history—the Wallachians. This race, who, like the Greeks, claimed the name of Romans or Romans, were the descendants of the Roman colonists in Dacia, whom the emperor Aurelian transplanted to the southern side of the Danube. There it is probable they intermingled with the natives, but they retained the Latin tongue, from which the modern language is derived. About the 13th century, it would seem, the great body of the nation once more migrated northwards to the seats they now occupy, but those of whom we are speaking here were settled on the Balkan, where they had maintained themselves in their mountain fastnesses, owing an allegiance more or less qualified to Constantinople. In the reign of

Walla
chians

Bulgars
Slavs
Greeks

Isaac Angelus (1186), however, when they were heavily taxed, robbed of their estate, and misused in other ways, they rose under the leadership of three brothers, Peter, Asan, and John, and having made a league with the Bulgarians, raised the standard of revolt, and established what is called the Bulgarian Wallachian kingdom. Its successive rulers contended with varied fortune against the Byzantine Government, but succeeded in maintaining their position in Thracian Macedonia, to which countries for a time it wholly also was added, forming, however, an independent province, with a governor of its own. The emperor Baldwin, the first of the Latin emperors of Constantinople, was captured by them in battle, and put to death. The kingdom continued to exist until the Turks made their appearance on the scene, when, in common with the other independent sovereignties in these regions, it was finally overthrown.

Style of
Greece

The period from the end of the 9th century to the fourth crusade was to Greece a time of prosperity. Though its inhabitants were looked down upon as provincials by the empire of Constantinople, and the country itself was treated with neglect (Basil II was the only emperor who for several ages visited Athens), yet in material well being it was one of the most flourishing parts of the empire. Though barbarian invasions were still not wholly unknown,—one of the Uzes in particular is mentioned in 1066,—yet security generally prevailed, and in the middle of the 11th century the country had nothing to fear from Saracen incursions. The land produced corn in abundance, so that it even supplied the capital in a time of dearth. The silk manufactures of Thebes, Athens, and Corinth were a source of great wealth, and much of the commerce of the time was in the hands of the people of Greece. The port of Monemvasia, in eastern Laconia, which gave its name to the Malmsey wine, was especially famous as a medieval emporium. How far Hellenic feeling and Hellenic traditions survived among the Greeks we have no means of discovering, but the probability is that these to a great extent perished, along with the Hellenic names, at the time of the great Slavonic immigration. The whole population had become Christian, though as late as the 9th century paganism existed among the inhabitants of the mountainous regions of Laconia. But in the latter half of the 12th century decline was ready to set in. Then commerce was passing into the hands of the Western traders, the silk manufacture was transferred by the Norman Roger to Palermo, and the profits of industry were absorbed by taxation, so that no surplus remained to be invested in works of public utility. The writings of Michael Acominatus, the noble and learned archbishop of Athens at the time of the fourth crusade, give clear evidence that in that city the decay had already commenced.

The
modern
language
and
literature

It is during the 12th century that we first meet with compositions in the popular Greek tongue, among the earliest specimens being poems by a monk called Ptochopodimos, addressed to the emperor Manuel Comnenus. The literary language of this time was still the same which had been used throughout the Byzantine period—the "common" dialect of the Macedonian Greeks, as it had been transmitted with various modifications by the later Greek writers and the fathers of the church. The Byzantine histories and other works which were composed in it are usually stilted and pedantic in style, and conventional in their ideas and their treatment of events, but it is possible to treat them too leniently. Some of the writers, like Michael Psellus and Eustathius of Thessalonica, were men of undoubted ability and learning, and, besides this, it was the taste for these subjects, however faulty, which maintained the high level of cultivation that distinguished the Byzantines from the people of all other contemporary states

during the Middle Ages, and caused the ancient literature to be preserved. This language was also that spoken at court, so that it is not till the time of the Palaeologi that we find the highest circles and polite conversation aided by the vulgar tongue. But from the 13th century after Christ, if not earlier, there had been a divergence, between the written and the spoken language, so that the two formed, so to speak, an upper and a lower stratum. Until the time of the iconoclasts, in all probability, the ancient speech was generally intelligible, but from the end of the 9th century it was a dead language to the great bulk of the nation. The change which the popular idiom was passing through, as might be expected, was twofold, arising, first, from the usual tendency of speech to become more analytical and of words to modify their meaning; and, secondly, from the loss of vocabulary, the mutilation of grammatical forms, and the confusion of syntax, which is produced by want of cultivation. At the same time it passed through no such violent process of denaturation as to tell Latin in its change into the Romance languages, so that its historical continuity was never broken. But when it emerges to view in the compositions of the 12th century it is already a modern language, and its forms differ little from those of the Romance of the present century, though of course the vocabulary was as yet free from the intrusive elements—Italian, Albanian, and Turkish—which subsequently crept into it. The metres in which these poems were composed was regulated entirely by accent, and not by the quantity of the syllables, and the verse usually employed was the so-called "political," i. e., popular verse, which corresponds to some of our longer ballad metres. The favourite subject was romances, and in the treatment of these, as well as to some extent in the stories themselves, subsequently to the Frankish occupation the influence of the French romances was clearly traceable.

V *Period of Greek Survival from the taking of Constantinople by the Latins to its Conquest by the Turks, 1204-1453 A.D.*

The empire of the East never recovered from the effects of the fourth crusade. It was then broken into a number of separate fragments, and though some of these recovered their cohesion, and the end did not arrive for two centuries and a half, yet the strength of the system was gone, and paralysis crept more and more over the enfeebled frame. In accordance with the provisions of the partition treaty, a Latin emperor was set up at Constantinople, and Baldwin, count of Flanders, was elected to the office. Latin kingdoms were established in different provinces,—one at Thessalonica, which was of short duration, another at Athens under the family of De la Roche, and a third in the Peloponnese under Champlitte and Villehardouin, which was called the principality of Achaia or the Morea. Of the occupation of the last-named of these countries an account is given in one of the most curious of mediæval Greek poems, *The Book of the Conquest*, the French original of which also exists. But even the districts which remained in the hands of the Greeks did not continue united. An independent empire was established at Trebizond on the Black Sea by a son of the house of Comnenus. Another principality was founded in Epirus, the despot of which, after overthrowing the Latin despot of Thessalonica, established at that place an empire of his own. But the headquarters of the legitimate Greek monarchy were at Nicaea, of Nicaea the original capital of the Seljuk sultans in Asia Minor. Theodore Lascaris, a man of no mean ability, who had been acknowledged as emperor before the capture of Constantinople, having taken up his abode in that place, succeeded in maintaining himself in opposition to the crusaders, the Seljuks of Iconium, and the Greeks of Trebizond, and his

Empire

successors continued to reside there for nearly sixty years. When the difficulties of the Western in Constantinople became increasingly acute, and their downfall appeared imminent, it was for a time a question whether that city should become the prize of the emperor of Nicea, or of the emperor of Thessalonica, or of the Bulgarian Wallachian sovereign, and this rivalry involved many alliances and wars. The man who ultimately decided it in favour of Nicea was Michael Palæologus, who became the founder of the last dynasty that ruled the Greek empire (1261).

The
Palæo-
logi

The character of Michael, which was too faithfully reflected by many of his successors, represented most of the unfavourable qualities of the Greek race. Though a brave soldier, he was intriguing, selfish, and unscrupulous, as he soon showed by the deposition and blinding of the young emperor, whose guards and colleagues he was appointed to be. He entered on the possession of a ruined capital, which the barons of the Western nobles had reduced to a state of poverty and filth, and his attempts to restore it were misdirected and unsuccessful. His one object, when he had established himself on the throne, was to maintain his despotism, and while he recaptured part of the Peloponnese to the empire, he ruined his subjects financially by debasing the coinage, and commercially by allowing the Genoese and Venetians to appropriate most of the carrying trade of the Greeks. But the act by which he gave the deepest offence was the reunion of the Eastern and Western Churches, which amounted to the subversion of the Greek Church to the pope, to which he consented at the council of Lyons (1271), in order to persuade Gregory X. to prohibit Charles of Anjou from invading the empire. The narrowness of the theological spirit among the Greeks at this period is greater than we can well conceive, but it was a not unnatural outburst of national feeling which caused the people in opposition to this measure. The subsequent attempt in the same direction at the councils of Florence and Ferrara (1438-9), when the nation was reduced to the quiet slumber, met with no better reception at home. Under the successors of Michael the empire continued for 170 years, but the whole of this time was a long death sickness. The doom of the empire was forecast by the powers that came to play on its weakness—the Catalans, who plundered those whom they had undertaken to aid, the knights of St John, who seized Rhodes, a conquest which they rendered memorable by their gallant defence of that island against the Mahometans, and the Serbians, who under Stephen Dushan, established an important empire, which lasted until it was destroyed by Sultan Amurath at the great battle of Cossova (1389). Even after the emperor themselves, from the endowments and gifts which they lavishly bestowed on monasteries, especially those of Athos, seemed to be providing beforehand for a day when their possessions would pass into the hands of others.

The
Ottomans

The nation was now arriving at the maturity which was to bring this time-worn empire to an end. Shortly before the Greeks regained possession of Constantinople, the Mongols, whose vast hordes had overrun a great part of Europe and Asia and had destroyed the caliphate of Bagdad, entered Anatolia, and shattered the power of the Seljuks of Iconium. But on the ruins of this dynasty another and far more terrible dominion arose. Towards the end of the 13th century Osman, the chief of a Turkish tribe in north-west Phrygia, penetrated through the passes of Mount Olympus, when the jealous policy of Michael Palæologus had denuded of the protection of the wallach mountaineers who occupied them, and descended into the lowlands of Bithynia. By his son, Orchan, the city of Broussa was captured, which became thenceforth the capital of the

Ottoman race. The extraordinarily rapid rise of this people to be one of the greatest powers that the world has seen was due in great measure to the remarkable ability of its successive rulers, but in no slight degree also to the institution of the *Jemias*—an inhuman but most efficient system, by which Christian children were torn from their homes and educated as Mahometans in the household of the sultans, to whose personal service, as a bodyguard, they were for life devoted. As early as the year 1316 we find Orchan's son, then the prime minister of John V., and afterwards himself emperor, entering into alliance with Orchan, and giving him his daughter in marriage. The first step towards a permanent settlement of the Turks in Europe was made in 1351, when Gallipoli was occupied by Orchan's son, Suleiman. Seven years from this time Amurath I. made himself master of Adrianople, and before his death that sultan saw the Greek emperor his vassal and tributary. It seemed now as if the fall of Constantinople could not long be delayed, when, with one of those turns of the wheel of fortune which form the surprises of history, Bajazet, the most powerful of all the Ottoman rulers, was defeated and taken prisoner by Timur the Tartar at the battle of Angora (1402), and civil war setting in between his sons gave the fifteen empires a new lease of existence. But within twenty years again the capital was besieged by Amurath II., though he failed to take it, owing partly to the strength of its fortifications, and partly to a rebellion that broke out in his family. The empire was now reduced to Thessalonica, a part of the Peloponnese, the city of Constantinople, and a few neighbouring towns.

In the midst of the gloom which hangs over this last period, it is consoling to find a ray of light that illumines the closing scene, in the heroic end of the last Constantine. The story is a sad one. The city was beleaguered by land and sea by the wallach hosts of Mahomet II., no further succour could be expected from the West, and the emperor, who had adopted the Latin rite, was thereby estranged from the great mass of his subjects. But he had determined not to survive his empire, and he died in a manner worthy of the greatest of his predecessors. On the eve of the final assault he rode round the positions occupied by his troops, to cheer them by his presence, and then, having partaken of the eucharist in St Sophia's after the Latin form, and having solemnly asked pardon of the members of his household for any offences, he proceeded to occupy his station at the great breach. There on the following morning, after a desperate resistance, he fell fighting amidst a heap of slain, and the young sultan passed his lifeless body as he rode into the captured city.

We have thus passed in review the fortunes of the Greeks during a period of nearly eighteen centuries. We have seen how the Roman system of government and the Greek character and social institutions, mutually influencing and modifying one another, produced the characteristic features of the Eastern empire. We have watched that empire maintaining a conflict on the one side with the invading barbarians, the Bulgarians, and the Western nations, on the other with the Persians, the Saracens, and the Turks, until to the last of these peoples it finally succumbed.

The following are the principal histories of this period—*an* English, Gibbon's *Decline and Fall of the Roman Empire*, which, from its comprehensiveness and grasp of the subject, can never be superseded, and *Fahey's History of Greece*, which is the chief authority on the Byzantine empire; in French, *Le Beau's Histoire du Bas-Empire*, in German, Carl Hoff's *Geschichte Griechenlands vom Beginn des Mittelalters*, published in Bielefeld and Gruber's *Byzantologie*, and is issued in vols. vi and vii of *Brookhouse's Griechische* (a work of great credit, which has cleared up many disputed questions), and Heitzberg's *Geschichte Griechenlands unter der Herrschaft der Römer*, and *Geschichte Griechenlands seit dem Absterben des antiken Lebens bis zur Gegenwart*, in Greek, *Βερεγγεγονόλης ἱστορία* (Β' & Γ' τμήματα) (H. P. 2).

SECTION III.—RECENT HISTORY

The history of Greece from the fall of Constantinople to the present day suggests a problem of profound historic interest. From the year 1453 till the end of the 18th century almost all the occasions on which the Greek people appear on the page of the historian are occasions on which we read of them that they were butchered or sold into slavery. Records tell only of their annihilation or disposition. Yet in the commencement of the 19th century this apparently annihilated and dispersed people can summon energy enough to resist the Turks, and although in all probability they would have failed to overcome their oppressors if they had been compelled to struggle unaided, yet the courage and self-devotion which they showed in the conflict were such as to gain for them the sympathies of Europe, and they came forth triumphant. But in reading even of their war for independence we are astonished that a remnant was left. Thousands upon thousands perished, and their victory seemed only less terrible than utter defeat. Yet the spirit of life remained. The kingdom of Greece was established, and within forty years, notwithstanding deplorable mistakes in its management, the population is doubled, and the country has become consolidated in a constitutional realm. To trace how these events were possible and how they actually came to pass is the task of the historian of Modern Greece.

The external events in this history are necessarily few. Greece was during the most of these centuries under the sway of foreigners, and the external history of Greece is formed mainly by episodes in the history of these foreigners. When Mahomet II became master of Constantinople, he did not thereby become master of the Greek empire. The Palæologi had held only a small portion of the territory which had constituted the Greek empire. Most of the islands of the *Ægean* were under the rule of Italian princes who acted as independent rulers. Rhodes was governed by the knights of St. John. But especially the Venetians owned large possessions in Greece and were also powerful by sea. The external history of Greece is occupied mainly with the efforts of Mahomet II and his successors to spread their conquests. Mahomet himself conquered the kingdoms of Trebizond, Albania, Eubœa, Greece proper, and part of the Peloponnesus. He was also successful in expediting against several of the islands of the *Ægean*, but he failed in his attack on Rhodes. It was not till the end of 1522 that the knights of St. John surrendered to Sultan I. after standing a siege in which they showed the greatest bravery, and in which the Ottomans, it is said, lost about 100,000 men. On the 1st of January the knights left the island, to go first to Crete and then to Malta. Cyprus and Crete remained still longer in the hands of the Westerns. In 1489 Catherine Cornaro ceded the island of Cyprus to the Venetians, who retained possession of it till, in 1570, Piri and Lala Mustapha attacked it. Nikosia fell in September 1570, and Famagosta in August 1571, after a brave defence conducted by Marcantonio Bragadino. The Turks received a severe defeat at Lepanto from Don Juan d'Austria in command of the combined fleets of Spain and Italy, in which they lost 130 ships and 30,000 men. But the blow was merely temporary. The helpers of Venice were not united among themselves. Again the Turks became the rulers of the *Ægean* Sea, and in 1573 Venice had to conclude a humiliating treaty in which she gave up Cyprus. In the case of Crete Venice had to pay for her own severity. That island remained for a long time undisturbed in the possession of the queen of the seas, as far as the Ottomans were concerned. But internal commotions agitated it. The Sphakioti or mountaineers of the southwest of Crete—a bold, brave, and independent race of men—

rebelled against the rule of the Westerns, and the Venetians had recourse to the most shameful cruelties and atrocities on all their Greek subjects in order to crush the rebellious spirit. The result was that the Greeks hated the Venetians with the bitterest hatred, and would have gladly welcomed a change to the rule of the Turks. The Venetians saw that they had gone too far, and sent a wise politician, Giacomo Foscarini, to bring matters to a better state. Many prudent reforms were inaugurated, the Sphakioti were reconciled, and all seemed to promise well. But Foscarini died before his reforms got firm hold of the people. The Sphakioti indeed from that day to this have never submitted to the Turkish yoke, but the rest of the people were far from willing subjects of the Venetians and favoured an invasion by the Turks. The Turks knew their opportunity, and began an effort to possess the island which, though the Venetians resisted with great perseverance and were backed by other Italians and by the French, ended in the treaty of 6th September 1669, in which they ceded Crete to the Turks. Thus last acquisition rendered the whole of Greece subject to the Turks, with the exception of the Ionian and a few other small islands, which still remained in the hands of the Venetians. The Venetians, however, did not resign their hold on Greece without a final effort to recover possession of it. For this purpose they not only hired soldiers from their own and other Italian communities, but also hired generals and soldiers from Germany. The war began in 1669. The management of it was entrusted to one of the greatest men whom Venice produced, Francesco Morosini, who was ably assisted by a Swedish general, Kongsmaak. The contest was carried on with great vigour until at length the Turks were driven from the Peloponnesus. The Venetians wished also to regain possession of Eubœa, but in this they were unsuccessful. The war was brought to an end by the peace of Cautowitz, which left Venice in possession of the Peloponnesus, and the islands of *Ægina* and Santa Maura. One incident in this war has especially attracted the attention of the civilized world. Morosini, finding his efforts successful in the Moria, resolved to advance towards Eubœa. Athens lay in his way. It was garrisoned by the Turks, who, however, on his approach quitted the lower city and, occupying the Acropolis, prepared to defend it at all hazards. They planted one of their batteries in a breach of the temple of Nike Aptetos, and they placed a portion of their powder and many of their valuables in the Parthenon. The Venetians showed no mercy to the most beautiful of all buildings, and one of their bombs, falling on the powder in the Parthenon, blew many of the masterpieces of art into a thousand fragments, and utterly defaced the noble building which had remained up till that time very nearly in the condition in which the original architect and sculptor had left it. The Venetians tried to introduce reforms into the Peloponnesus, and had made considerable progress when in 1716 Ali Kumurgi, at the head of a very large Ottoman army, entered the Peloponnesus. The Venetians were unprepared, and they could not easily get assistance from others. The consequence was that in a very short time Kumurgi drove them out of the whole of the peninsula. The Turks got involved at this time in war with Austria, and when peace was finally concluded at Passarowitz, Venice had to give up the Moria as well as the island of *Ægina*, and practically she disappears from the history of Greece except as the possessor of Santa Maura. But a great change had now begun to take place in European politics. At an early period after the capture of Constantinople the Turks came into collision with their neighbours on the north, the empires of Austria and Russia, and we find these two powers united in resisting the marauds of the Ottomans. Even so late as 1683 the Turks were so bold as to advance as far as Vienna and lay

siege to it. But in the 14th century the policy of Russia attracted the attention of the rest of Europe, and caused a considerable change of attitude. Early in that century Peter the Great had declared his resolution to force his way into Constantinople, and though he was completely balked in his aim, and had to sign an ignominious peace (1711), the desire to have this city on the Bosphorus continued to animate the Russians. It is to Count Munnich, field-marshal and counsellor of the Russian empress Anna, that historians attribute the suggestion that Russia should systematically stir up the Greek Christians against their Turkish masters, and from his time (1730) onward we find Russia continually scheming to rouse the Greeks to insurrection. Most famous amongst these efforts were those of the empress Catherine II who, influenced partly by the Philhellens of Voltaire, partly by a desire to withdraw the attention of her subjects from domestic affairs, but principally by a wish to gratify her favourite Orloff, formed the project of emancipating the Greeks from the yoke of the Turks (1769). But all the efforts made to effect this object were exceedingly inadequate. The Greeks were soon taught also that Russia, while willing to free them from the Ottoman yoke, was determined to assert none but those who would readily become Russian subjects. And the expedition to the Peloponnese undertaken by Orloff was followed by most disastrous consequences to the Greeks. The Russians were more successful in their contests with the Turks in the north, and in 1774 compelled the sultan to accept a peace, called the peace of Kainarj, which contained several provisions bearing upon the Greeks. In some of these the sultan promised to protect the Christian religion and Christian churches, and though no special mention was made of Russia, her statesmen saw in this stipulation an opening for endless opportunities to interfere. And from this time forward Russia has claimed to be the champion of the Christians against the Turks. But the other states of Europe, especially France and England, became suspicious of the designs of Russia, and looking to the balance of power as an essential principle of European statesmanship, they determined to maintain the integrity of the Turkish empire. Austria had frequently joined with Russia in opposing the Turks and had again and again hoped to come in for a share of the spoil when Turkey should be partitioned. But towards the end of the 18th century the increasing power and influence of Russia began to alarm her, and when the Greeks rose to assert their independence, no power more tenaciously adhered to the doctrine that the integrity of the Turkish empire was demanded by the balance of power in Europe. Thus up to the time of the establishment of the Greek kingdom the affairs of the Greeks have been mixed up with those of foreigners—Ottomans, Venetians, Austrians, Russians, and the other European powers.

The notable fact in Greek history during these ages is the disimprovement and the apparent destruction of the nation. Whoever might hold the supreme power in Greece, the Greeks were sure to be the sufferers. When the Turks spread their conquests from Constantinople on to the rest of the empire, every capture of a city was followed by the slaughter of the able-bodied men and the carrying off of the women and children to the harem or slave market. And the Western Christians were not a whit more tender than the Ottomans. The Venetians were wroth with the Greeks, because they did not acknowledge the pope, and in the island of Crete perpetrated the most abominable barbarities on the innocent population. The Turks punished the Greeks because they submitted to the Venetians, and the Venetians punished them because they submitted to the Turks. Moreover, in these times the *Ægean* was infested by pirates who, whether Turks or Italians or Greeks, had

no money on the peaceful inhabitants of the mainland. Human life was devalued, and men and women were of value only in so far as they were saleable articles in the slave market. If one were to enumerate all the instances in which historians tell us of the utter destruction or transference of the Greek population, a vivid idea might be presented of how terribly hard were the sufferings of the Greek people. We have to add to this record of destruction that vast masses of the people removed to Italy or Sicily or some other place of refuge. Almost all the famous families that ruled the islands of the *Ægean* escaped from them when they were attacked by the Turks. The knights of St John, for instance, left Rhodes to find a final settlement in Malta. Among the number who thus left their native land were nearly all the learned men, who sought in the West a refuge from Turkish rule, and opportunities for the pursuit of learning.

Yet notwithstanding these destructive forces the Greek people survived. To understand this phenomenon we have to examine into the mode of civil administration adopted by the Ottomans. The Ottomans were pre-eminently a warlike people. Their profession was that of arms. Their two great objects in life were to conquer and enjoy their conquests. They were brave and always ready to fight, but after battle was over they wished to enjoy the luxury and repose with which they had gained it. They were therefore utterly disinclined to meddle with civil matters. If they got their revenues, and could enjoy their homes and slaves, it was a matter of no consequence to them how the subject races procured the means of paying the taxes, or in what way they governed themselves. The same spirit showed itself in the sultans. To them all Turks as well as Greeks were practically slaves. The sultans saw in the Turks the right hand that could bring them success in war, and in the Greeks or other subject nations the means of ministering to their wealth and enjoyment. Provided they had a sufficiently numerous and brave army and ample supplies of money, they were comparatively indifferent how or by whom local affairs were managed. This freedom from bias and this singleness of purpose enabled them to continue their power for a much longer time than they could possibly have done had they been swayed by national aims or particular ambitions. They had no hesitation in selecting for their purposes the best men they could get, and consequently many of the subject races rose to places of high eminence in the Turkish army and administration. A large proportion of the viziers of the Sublime Porte have been Greeks. Many of the generals that subdued Greece were Greeks. There was thus a constant accession to the ranks of the Turks from the subject nations. Those who thus entered the Turkish service could not do so without adopting Mahometanism. It was the essential condition. But many Greeks found no difficulty in changing their faith. They saw that it was then one hope of rising to eminence. And these men reached such high positions as to arouse the jealousy of the Turks, for the sultans preferred the converts to the original Mahometans. They felt more confidence in them as instruments of their own domination. Indeed at one time there seemed a likelihood that large portions of Greece would become entirely Mahometan. They were urged to it by two opposite influences—by the high position which Mahometan converts from Greece could attain, and by the utterly wretched condition of those who remained attached to the Christian religion. We have a curious instance of the effect of the latter motive in the conduct of the Carmunates who occupied about thirty-six villages in the valley of the Acrois in Albania. The inhabitants of these villages had long been oppressed by the Mahometans, but had remained Christian until 1760. In that year matters came to a crisis

The Caramanliades could stand then distress no longer. They agreed that either Christianity was not true or it ought to put them in a better position. They resolved to give it one chance more, and to try to conciliate the Divine Being by the most rigid fasts. If He did not listen to them, then they would feel assured that He did not wish them to remain Christians. The chief priest protested against the impicity of this resolution, but the Caramanliades would not listen to him. They observed Lent with the most rigorous severity, and played much. No improvement followed in their lot, and accordingly, on Easter day, they told the priests to retire, accused the sacred images of being indifferent to their distress, and in one body went over to the faith of Islam. A very few indeed refused to join their brethren, but they had to retire with the priests. At an earlier period, from 1620 to 1650, the Christian population of a part of Albania fell from 350,000 to 50,000, and to the present day a portion of the Albanians have remained firmly attached to Islamism, and have been the readiest tools in the hands of the Turkish Government, while the other portion have stood by the Greeks in their struggles for independence, and have done great and valuable service to the cause. In fact, so great was the inclination of the Greeks to adopt Mahometanism through the combined motives already mentioned that the sultans were alarmed lest they should have no tribute-paying people at all, and accordingly they began to be kind to the Christians, to give the tribals or subject Christians, and did much to reconcile them to their government.

Another mode in which the Greeks passed over to Islamism has been already noticed. Even before the taking of Constantinople Orkhan had ordained that the children of Christians should be taken from them, should be specially trained for military service, and should enjoy such privileges and immunities that they would feel themselves specially bound to the sultan. The practice was continued and extended by Mahomet II. Every fifth Christian child had to be surrendered to the service of the sultan. All connexion with his parents was cut off, and he was set apart and trained for warfare. In this way was formed the corps of the Janissaries. The Janissaries were not at first permitted to marry. Their ranks were constantly recruited from the Christian children. History speaks in the highest terms of the discipline and courage of this body of troops while it flourished. The Janissaries forgot altogether, if they ever knew, their homes and their hearths, and they were equally savage to Turk and Christian in their devotion to the sultan. This hateful sacrifice imposed upon the Christians gradually came to be regarded as an honour. The parents knew that their children were to be removed from the degradation of Christian slavery, and were to occupy the best positions that were open to Mahometans, and the Turks themselves so much valued the honour for their children that they bargained with the Greeks to take their children and give them for Janissaries instead of their own. A change took place at length in the composition of the Janissaries. They were allowed to marry, by degrees a position in the body became hereditary, and thence is dated the falling off of the corps. The tribute children were no longer required, and in the reign of Mahomet IV (1649-1687) the tribute ceased.

In all these instances the Greeks were practically lost to their own nation. They disappeared from the nation of Greeks and Christians and became Turks and Mahometans. At the same time we cannot help supposing that by this introduction of a new element of progress, or at any rate of restlessness, was thus introduced into the dormant race.

But the Greeks attained to positions of eminence in which they were not compelled to abandon their nationality. Between the Turks and the Greeks existed irreconcilable

difficulties. Not only was there religious difference, but they differed widely in their social position. There was no hope of amalgamating the two races. The Turks could only convert or exterminate the Christian. They did not want to do that, but they could convert all the Greeks, by persuasion, and forcible conversion after the age of twelve was forbidden by the Koran. The only other alternative was extermination, and one of the sultans came to this resolution to destroy every Christian. But the Turks saw that such a policy was ruinous to themselves. Every Christian paid a poll tax from which every Turk was exempt. The Christians cultivated the lands for the benefit of the Turks. The Christians were the diademes of the Turks. The next best thing to extermination then was to get as much out of the Christians as possible while coming as little as possible into personal contact with them. This was the plan adopted. Immediately on the conquest of Constantinople, Mahomet spent the Turkish system of administration over the whole of Greece. The Turkish warriors received lands during their life on condition of being ready to serve in war. These had captives who received the highest of larger portions of land, and finally pashas acted as military and civil rulers of still larger portions. All these were ready to keep the Greeks in subjection, and crush every effort at rebellion, and they guaranteed the taxes to the sultan. Turkish courts of justice were also established. But Mahomet II did not disturb the Greek modes of civil administration which he found in force. They merely became subject to his purposes, and appeal could always be made from a Greek to an Ottoman institution. Mahomet II especially made use of the Greek clergy as his tools for keeping the Greek people quiet and submissive in paying taxes. The Greek emperor had perished in the sack of Constantinople, and the nobles had either fallen or fled or been butchered shortly after. But the Greek Church still remained. The Greek people were devoted to their church. Their quarrels with the pope had only strengthened their attachment to it. Here was an instrument that Mahomet thought might be of great use. Accordingly he made the patriarch of Constantinople the representative of the entire Greek people. He gave him privileges and honours, but he made him responsible for the conduct of the Greeks. The Greek clergy had long before taken an active part in the administration of justice. The bishops had the decision of all questions connected with marriages and wills. They were consulted by their people not merely in spiritual but in nearly all civil matters. The sultan had hold of this clerical influence through the patriarch. He practically appointed the patriarch, the patriarch appointed the bishops. All the great officials of the church thus held their positions under the sanction of the sultan, and could be removed by him. There is no doubt that patriarch and bishops and higher clergy, thus playing the humiliating part of keeping their fellow-countrymen in due subjection to the Porte, did not and could not display very high virtues. They soon contracted all the vices which defile men who have to play a double part; they were true neither to the sultan nor to the Greeks, and they were animated generally by a mean and selfish ambition. By degrees the patriarchate came to be bought from the sultan by higher and higher prices. The patriarch made up his losses by selling the bishoprics, and amony thus became universally prevalent. Notwithstanding all these drawbacks the maintenance of the Greek Church helped to keep the Greeks together, and when a better time came, the high positions which the clergy held enabled them to accomplish much for the spread of enlightenment and the awakening of true national feeling. Even in the darkest times patriarchs appeared who were capable of the greatest sacrifices for their church and nation, and in

the war of independence several of the clergy stood in the front rank. The inferior clergy throughout the whole time were true to their people, but it is they who to a large extent made the war, and it is mainly on themselves by some hands of the clergy, suffered in no respect from the great body of the people, to whose industry and zeal with the palm-tree of the nation is mainly due.

Another circumstance favorable to the Greeks was that the Ottomans allowed them to retain the communal system which had existed in earlier times. By this system, which, however, did not prevail in all parts of Greece, and where it did exist was not carried out always to the same extent, all the males of full age in each district elected a man who was to take special charge of local affairs. These men went by various names, such as demogerontes, gerontes, archontes, præsides, in epitaphs. The Ottomans found the system useful. The pascià had to keep on good terms with the Turks, and was indeed frequently farmers of the taxes from the Turks. They were also often exceedingly ambitious and cruel. But they were often men of intelligence and influence, and when the war of independence broke out, some of them took a prominent part. There cannot be a doubt also that the local self-government which was thus allowed to exist helped to keep up the longing for liberty and to prepare the nation for a constitutional government.

The Greeks showed their aptitude for combination and self-government also in maritime affairs. From an early period they had taken to mercantile pursuits, and their position was in many respects advantageous for trading. The Turks were not successful in trade, and indeed did not care to pursue it. They therefore willingly left it in the hands of the Greeks, and various events and circumstances had favored them. The Turks imposed a heavier duty on goods exported or imported by Greeks than on those possessed by Turks. The result of this regulation was that the sultan was led to his interest to encourage Greek rather than Turkish traders, as his revenue from the former was much greater than from the latter. Various privileges were gained by the Russians for their own traders, and the Greeks were permitted to enjoy these under the Russian flag. Then, during the war which France waged against all Europe, Turkey was for a long time neutral, and the subjects of Turkey could trade where no others could. Under these and similar conditions the Greek traders spread themselves over the whole of the Mediterranean, and many of them became very wealthy. In this prosperous state of matters various Greeks combined and founded large joint stock companies. Thus the association of Amphilochi, employed principally on cotton fabrics, embraced twenty-two villages. All the inhabitants of twenty-five years and upwards had a right to vote in the election of the Ottomans, especially the Maniotes of the Peloponnese and the Sphakiotæ of Crete. Many Greeks had led an independent life as pirates or as klephts. Piracy was indeed put down by the European Governments, but the klephts or brigands remained living on plunder of Greek and Turk alike, proud of their liberty, in their hill fastnesses. There were also in Albania, Thessaly, and Greece proper bodies of Christian warriors, called armatoli, who acted as bands of armed police, but whose actions came often to be confounded with those of the klephts. In regard to the others, Greeks it must be affirmed that they were broken in spirit. Finlay asserts that they never once rose against their oppressors. Paparrhægopolis tries to show that the very opposite was the case, but all he proves is that the Greeks were ever ready to take up arms against the Turks at the instigation of any foreign power. They rose up invited by France, by Spain, by the Venetians, and in other times they were continually rising through the secret instigations of Russia. But they never once rose of their own accord.

These were other positions of still greater eminence to which the Greeks rose. The Ottomans for a considerable time after the fall of Constantinople were characterized by a strong literary spirit and a desire for culture, but this spirit declined, and the pursuit of learning was left to the Greeks. But a European Government requires men of culture, if for no other purpose, at least that it may hold intercourse and enter into negotiations with the other European powers. The Ottomans felt this necessity, and accordingly in 1686 they appointed Panayotes Nicousses dragoman or

interpreter. He was succeeded in this office by Alexander Mavrocordatos, who highly distinguished himself in various political transactions of great importance. The office of dragoman became permanent, a Greek was always appointed, and thus Greeks came to have rare opportunities of influencing the sultan. Not long after the establishment of this office another was instituted, that of dragoman or interpreter to the capitan pasha or chief Turkish admiral, whose business it was to arrange all matters connected with the fleet. Still further, the Turks thought it advantageous that the northern provinces of Wallachia and Moldavia should be ruled by Greeks, and generally those who had acted as interpreters to the sultan or to the capitan pasha were appointed as warwodes or hospodars of Wallachia. These men became practically kings of these provinces, and Greeks from all parts flocked to hold offices under them. The Greeks who received these high appointments lived, when their duties did not call them away, in the part of Constantinople called Phanariot in which the patriarchate was placed, and hence they were called "Phanariots." They increased greatly in number, and at length formed a large, powerful, and wealthy community in the city of the sultan. The character of these phanariots has not been painted in bright colours by historians, but their circumstances were strongly antagonistic to the development of a high moral tone. They had above all the general favour of the sultan, and to stand well with the influential Turks. They could accomplish this only through double dealing and through extortion. They were also ambitious, and had no scruple as to the means employed in attaining the objects of their ambition. It is affirmed that the Wallachians and Moldavians detested their rule even worse than that of the Turks, but this can be accounted for satisfactorily by the consideration that nothing could be more humiliating than to be ruled by men who had the appearance of princes but were in reality slaves, without our supposing that their rule was more than ordinarily cruel and rapacious. And much has to be said in their favour. They had the strong Greek love of culture. They sent their sons to the best universities in Europe, and in this way the phanariots became men of great refinement and intelligence. Many of them took a distinguished place in the history of their country's literature. They also established schools everywhere, and vigorously supported those they found existing. The schools or rather colleges of Bucharest and Jassy rivalled that of Jannina in the number of able men they trained to guide and animate their country in its seasons of perplexity.

It was through these and similar instruments that the Greeks were being prepared during the Turkish and Venetian rule to struggle for their independence. Some of the Greek tribes had never been perfectly subject to the Ottomans, especially the Maniotes of the Peloponnese and the Sphakiotæ of Crete. Many Greeks had led an independent life as pirates or as klephts. Piracy was indeed put down by the European Governments, but the klephts or brigands remained living on plunder of Greek and Turk alike, proud of their liberty, in their hill fastnesses. There were also in Albania, Thessaly, and Greece proper bodies of Christian warriors, called armatoli, who acted as bands of armed police, but whose actions came often to be confounded with those of the klephts. In regard to the others, Greeks it must be affirmed that they were broken in spirit. Finlay asserts that they never once rose against their oppressors. Paparrhægopolis tries to show that the very opposite was the case, but all he proves is that the Greeks were ever ready to take up arms against the Turks at the instigation of any foreign power. They rose up invited by France, by Spain, by the Venetians, and in other times they were continually rising through the secret instigations of Russia. But they never once rose of their own accord.

The reason was that they had no means of taking combined action. The great bond of sympathy which attached the various Greeks together during the 16th and 17th centuries was their religion. But a new inspiration came with the advance of culture in the end of the 18th and the beginning of the 19th century. They began to be animated by the feeling of nationality. The French Revolution roused their minds into activity, and they were ashamed that a nation which had played such a grand part in the early civilization of mankind should be the slaves of an illiterate and barbarous horde of aliens. Circumstances favoured the movement. Especially prominent amongst these was the conduct of Ali Pasha, the tyrant of Janina. This daring and successful despot conceived the idea of cutting his connection with the sultan and assuming the absolute government of Albania. His effort showed how weak the Turkish empire was, and how loosely it held together. Stimulating also was the conduct of the Sulioti, who performed prodigies of valour in their resolution to defend their homes and their liberties. A secret society was formed to make ready for a rising of the people. The people were stimulated by patriotic songs, especially those of Rhigas of Velestino, and the agents of Russia were everywhere.

Accordingly in 1821 the war for independence broke out. It would be impossible in the limits of an article like this to give a proper account of the various contacts between Greeks and Turks, of the quarrels among the Greeks themselves, and the windings of European diplomacy in its interference in the contest. The principal events may be shortly noted. The insurrection was begun by Prince Alexander Hyspalantes, a Phanariot in the service of Russia, who had been elected head of the chief secret society (the *φύλαξ τραπεζία*). He crossed the Pithul March 6, 1821, with a few followers, and was soon joined by several men of great bravery at the head of considerable troops. But the expedition was badly managed, and in June Hyspalantes fled to Austria, having entirely failed in his object. And in all the efforts to overthrow the power of the Turks in the northern provinces the Greeks failed, though some men fought very bravely. In the Peloponnese the insurrection broke out also in March in several places, and most prominent among the first movets was Gormanes, archbishop of Patras. Everywhere the Greeks drove the Turks before them, they were so successful that in January 1822 the independence of Greece was proclaimed. But they soon began to quarrel among themselves. Several assemblies were held. Mavrocordatos, one of the Phanariots, was appointed president. But the aspirants for honours and rewards were numberless, and they could not agree. Accordingly a civil war raged in 1823 and 1824, inspired by Colocotronis, a chief of klephts who attained great influence, and in 1824 another civil war of short duration, called the War of the Primates. During this period the Greek fleet was very active, and did good service. It was ably led by Mionis, a man of firm character and great skill. And he was well seconded by the intrepid Canaris, whose fire ships did immense damage to the Turkish fleet, and filled the Turkish sailors with indescribable terror. For the ravages of the Greek fleet the Turks wreaked fearful vengeance on the innocent inhabitants of the lovely island of Chios (April 1822), butchering in cold blood multitudes of its peaceful inhabitants, and carrying off others to the slave market. The savage atrocities then perpetrated caused a thrill of horror throughout the civilized world. Two years after they perpetrated similar outrages on the islands of Ios and Paros. The sultan now invoked the aid of Mehmet Ali, pasha of Egypt, and his stepson Ibrahim landed on the Peloponnese with a band of well-disciplined Arabs in 1824. Ibrahim carried everything before him, and the Greeks lost nearly every

place that they had acquired. Some towns offered a strong resistance, and especially famous is the siege of Missolonghi, which lasted from 27th April 1825 to 2nd April 1826. Nothing could exceed the immensity and bravery displayed by Greek men and women during that siege, and their glorious deeds and sad fate attracted the attention of all Europe. The interest in the Greeks, which had been to some extent aroused by Lord Byron and other English Philhellenes in 1823, now became intense, and volunteers appeared from France and Germany as well as from England and America. Lord Cochrane was appointed admiral of the Greek fleet, and Sir Richard Church generalissimo of the land forces, but they did not prevent the capture of Athens by the Turks, 2d June 1827. Most of the European Governments had remained indifferent, or had actually discouraged the outbreak of the Greeks. Russia had disowned Hyspalantes. The monarchs of Europe were afraid that the rising of the Greeks was only another eruption of democratic feeling fostered by the French Revolution, and thought that it ought to be suppressed. But the vast masses of the people were now interested, and demanded from their Governments a more liberal treatment of Greece. Canning inaugurated in 1823, and now carried out this new policy in England. An accident came to the aid of the Greeks. The fleets of England, France, and Russia were cruising about the coasts of the Peloponnese, to prevent the Turkish fleet ravaging the Greek islands off mainland. Winter coming on, the admirals thought it more prudent to anchor in the Bay of Navarino, where the Turkish fleet lay. The Turks regarded their approach as prompted by hostile feelings and commenced firing on them, whereupon a general engagement ensued, in which the Turkish fleet was annihilated, 20th October 1827. Shortly after (18th January 1828) Capodistrias, who had been in the service of Russia, was appointed president of Greece for seven years, the French cleared the Moira of hostile Turks, and Greece was practically independent. But several years had to elapse ere affairs reached a settled condition. Capodistrias was Russian in his ideas of government, and, ruling with a high hand, gave great offence to the masses of the people and his rule came to an untimely end by his assassination on 9th October 1831. Anarchy followed, but at length Otho of Bavaria was made king, and the protecting powers signed a convention by which the present limits were definitely assigned to the new kingdom (1832). Henceforth Greece has existed as a recognized independent kingdom. Throughout the whole of the war of independence in Greece, the people behaved with great bravery and self-sacrifice. They showed a steady adherence to the idea of liberty. They were sometimes savage in their conduct to the Turks, and barbarities occurred which stain their history. Yet on the whole the historian has much to praise and little to blame in the great mass, especially of the agricultural population. But no single man arose during the period capable of being in all respects a worthy leader. Nor can this be wondered at. All the men who took a prominent part in the movements had received their training in schools where constitutionalism was the last doctrine that was likely to be impressed on them. Several of them had been in the service of Russia, and had full faith only in arbitrary power. Many of them were Phanariots, accustomed to double dealing, ambitious and avaricious. Some of them had been brought up at the court of Ali Pasha of Janina, and had become familiar with savage acts of reckless despotism. Others had been and indeed remained during the continuance of the war chiefs of klephts, having but little respect for human life, and habituated to scenes of cruelty and plunder. Some of them also came from the Manoties, who owed their independence to the habitual use of arms, and

who were not troubled by many scruples. It could not be expected that such men would act with great mercy or patience in dealing with Turks who had butchered or enslaved their kinsmen and kinswomen for generations. Even amongst the foreigners who volunteered to aid the Greeks, few if any were found of supreme ability, and after the kingdom was established the Greeks were unfortunate in the strangers who came to direct them. Otho had been brought up in a despotic court, and knew no other method of ruling. He brought along with him Bavarians, to whom he entrusted the entire power, and the Greeks had the mortification of knowing that, though their kingdom was independent, no Greek had a chance of being elevated to any ministerial office of importance. Accordingly a revolution broke out in 1833, the Bavarians were dismissed, and Otho agreed to rule through responsible ministers and a representative assembly. But he failed to fulfil his promise. Discontent reached its height in 1832, when another revolution broke out and Otho had to leave Greece. The great mass of the people longed for a constitutional monarchy, and gave a striking proof of this by electing Prince Alfred king of Greece. This choice was determined by universal suffrage, and out of 211,202 Greek citizens who voted 230,016 recorded their votes in favour of the English prince. The vote meant simply that the Greek people were tired of unconstitutional princes, and hoped that they would end their troubles if they had a prince accustomed to see parliamentary government respected and enforced. The three protecting powers—England, France, and Russia,—had however bound themselves to allow no one related to their own ruling families to become king of Greece. When the Greek people received this news, they begged England to name a king, and after several refusals England found one in Prince William of Schleswig-Holstein, son of the king of Denmark. The Greek people accepted him, and in 1833 he became king with the name of George I. Britain added the Ionian islands to his kingdom. In 1876 the ministry gave great offence to the Greek people by its unconstitutional procedure, and the king persisted in the use of it. The people, however, persevered in the use of

legitimate means to oust the ministry, the king at last prudently yielded, and thus a revolution was prevented. The effort of the Greeks to extend their boundaries is the last phase of their history, and is still in progress. In 1853 when the Crimean war broke out, the Greeks sided with the Russians, and in 1854 they made incursions into Thessaly and Epirus, but English and French troops landed at the Piræus, and forcibly put an end to the Russian alliance and to Greek ideas of acquiring additional territory. In 1866 to 1869 the Cretans struggled bravely but unsuccessfully to throw off the Turkish yoke and become a part of the Greek kingdom. And recently when the Russians made war on the Turks the Greeks were eager to join Thessaly and Epirus to aid their fellow-countrymen in asserting their freedom. But England interfered with the promise that Greece would gain more by maintaining a peaceful attitude. A clause in the Berlin Treaty affords a basis for the fulfilment of this promise, but the promise has still to be fulfilled. The Greeks themselves believe that with the extension of their boundaries there will be less occasion for intrigue, ministries will be more permanent, and the Greeks who now flock from all parts to the little kingdom of Greece for official employment will have a wider sphere and will be more contented.

The authorities for this section, some of which have been mentioned in the previous article, are very numerous. See, e.g., the *topography* of Papadopoulos, vols v and vi, and his *Etica* II work *Zeitschrift für vergleichende Hellenistik*, vols v, vi, and vii; Hatzberg, vols iii and iv; Kailhaidelovich-Batholdy's *Geschichte Griechenlands von der Eroberung Konstantinopels durch die Türken im Jahr 1453 bis auf unsere Tage*, Berlin, 1883; *Topographie*, and the *Chronicon* in his *Historische Geographie*, 1881; and Geary's, *Geschichte des neuellenen Jahrs*, vols v and vi. For the Greek Revolution, besides the four first mentioned, there are Gordon and (in modern Greek) Thukydides. There are many treatises on special portions, such as those of Thukydides, Philon, Phanias, Colocotronis, Von Maurer, Prokisch, Ostre, Pöhl, and many monographs on the history of the various islands. Most of the English works are in the list by Gluckstein, "The Hellenic Factor in the Eastern Problem," published last in the *Contemporary Review*, and now in his *Gleanings*, Freeman's *Ottoman Power in Europe*, Sargent's *New Greece*, and "Mr Gladstone and the Greek Question," being in it *Diplomatic Sketches by an Outsider*. (J D)

PART III—GREEK LANGUAGE

The possession of a common language was always regarded by the Greeks themselves as the most significant and important of the bonds which united the scattered members of the Hellenic nationality. Wherever there was a community speaking the Greek tongue, whether in Europe, Asia, or Africa, from Olbia on the Hypanis to Cyrene in Libya, from Salamis in Cyprus to Melos near the Pillars of Hercules, there was a portion of the Hellenic people linked to the rest by mutual intelligibility, and sharply marked off from the jabbering and inarticulate *Barbaroi* who surrounded them. The earliest written records of this speech are probably to be found in what was at the same time the most precious common possession of this great nationality, the poems that bear the name of Homer. It is possible indeed that, in the form in which they have come down to us, they are later than the fragments of the earliest elegiac and iambic poetry, such as Callinus, Mimnermus, Archilochus, and Simonides of Amorgos, but it cannot be doubted that in substance they go back to an earlier date. These, however, are in a literary language,—a language which bears the most evident marks of a free combination for artistic purposes of various popular dialects, along with many reminiscences of archaic forms and usages, and not a few formations due only to false analogy. For the early history of the Greek language we are obliged to have recourse to the reconstructions of linguistic science,

Origin of the Greek Language

Comparative philology shows us that there was a time when the ancestors of the various nations which speak common what are generally known as Indo-European languages lived together and had a common speech. From the extent and character of the agreement between these various languages at the time when they first became known to us from written records, it is possible to a certain extent to determine which groups remained the longest in connection with each other, and which parted off the soonest from the common stock. Unfortunately scholars are as yet by no means at one as to the results to which this method of inquiry leads us. Schleicher, e.g., held that the agreement between the Aryan or Aryan group of languages and the South-European (in which he includes not only Greek and Italian, but also Celtic) is closer and more significant than that between the latter and the North-European, e.g., the Teutonic and the Letto-Slavonic group. Max Müller and Joh. Schmidt maintain that the relations of the various languages are so complicated that it is impossible to establish any "genealogical

¹ The numerous and trouble objections to the term "Aryan" have been often pointed out, and the word has little favour with most philologists. For the most recent discussion of it see Zimmer in *Beiblätter zur Zeitschrift*, vol iii pp 187-188. The name "Indo-European" is apparently, but not really, more exact.

ties," or to determine the order in which they separated from each other (see Schmidt's *Die Verwandschaftsverhältnisse der Indogermanischen Sprachen*, Weimar, 1872). But the prevailing view is still that of Lettner, Curtius, Jolly, Fick, and Scherer, that we may with confidence assume the first division to have been that between the Aryan or Asiatic (Indo-Persian) and the European groups, and that there are sufficient points of agreement between all the European languages to warrant us in assuming that there was a period of some duration during which the European peoples remained united.

Of these points of agreement the most important are the following:

The common European language

1. The vowel *a* is found to have "split" on European soil into the three vowels *a*, *o*, *u*,—like it is to say, that the numerous instances in which the European languages agree in regarding a primitive *a* into *e* or *i* when the Asiatic tongues either retain the *a* or weaken it quite indifferently into *e*.

2. The European voice in reducing a primitive *u* into *i*, where the Asiatics have retained *u*.

3. There is a large number of new words, and apparently even some new roots, common to most, if not to all, the European languages, of which no trace is to be found among the Indo-Persians.

These facts cannot be set aside by instances of agreement in inflexion or syntax between Greek and Sanskrit, for example, for it is much easier to believe that at the comparatively late date at which any European language is known to us,—and much more so, at the far later date of the earliest Celtic records,—the inflexions which they presumably once had in common with Greek had become to a large extent worn away and unrecognizable and the syntactic constructions modified, than to suppose that such numerous instances of agreement were wholly fortuitous.

The Græco-Italic language

A similar course of argument fairly leads to the presumption of a common Græco-Italic nationality. The agreement in vocabulary is still closer than that between the various members of the united European group for instance, while the general terms for agriculture are shared not only by Greeks and Italians, but also by Teutons, Celts, Slavs (though not by Indo-Persians), there are many special terms which are only found on Greek and Italian soil, the most interesting among them being perhaps the words for *wine* and *oil*. Other words, again, which are used with a more indefinite meaning by the Europeans generally are specialized and differentiated in Græco-Italic (Fick, *Vergl. Wörterb.*, u pp 1-288, Curtius's *Principles*, 230b, 234, 507, &c.) Whether we may also assume (as is done, e.g., by Professor R. Curtius, *History of Greece*, vol 1 p 19) that there was a common Græco-Italic law of accentuation is very doubtful, in face of the arguments advanced by Curtius in favour of a free law of accents in the earlier times, both in Greek and in Latin. It is much more probable that the rigidity of the Latin system, and the exquisite flexibility and harmony of the Greek, were developed quite separately from a more fluid state. But undoubtedly there is a far greater similarity in the inflexional system of Greek and Latin than can be established between either of these and any other member of the group.

Stages of development in inflexion

At the time when the common Indo-European unity was first broken up, the language had reached a stage of development which may be given with some confidence as follows. The steps assumed are those which have been established by Professor Curtius in his monograph, *Die Entwicklung der Indogermanischen Sprachlehre* (2d edition, Leipzig, 1873). In spite of the criticisms to which this scheme has

been subjected, by far the most important of which are those by Max Müller and Ascoli, it may fairly be said to maintain its ground, and is reasserted with full confidence in Curtius's admirable work on the Greek verb.

We start with the period in which roots alone were employed as words. As to the origin of these roots, philology is as yet quite unable to speak with any positiveness. All that can be said is that the imitative or onomatopoeic theory has not been proved to be capable of producing all the roots which we are compelled to postulate, while, on the other hand, no theory has been generally recognized as fit to be regarded as a serious rival. It is clear, however, that we must admit an extremely early, if not an absolutely primitive, distinction of roots into verbal and pronominal roots, e.g., (1) such combinations of sound as were significant, and carried with them a notion which was vague and general, if not philosophically abstract, and (2) such as had no meaning in themselves, but only served to denote relations.

The second stage is that of the "determination" of roots, roots wherein, by the addition of different phonetic elements, they acquired a differentiated meaning—e.g., when the very vague *ju*, "join," became *ju-g*, "join together," *ju-da*, "join in battle" (It may here, however, be open to question whether the fuller forms were developed from the shorter by additions, or the shorter abstracted from the group of similar fuller forms, as Max Müller is rather inclined to hold).

The third stage is that of the formation of verbs, by the close combination of a verbal root with one or more pronominal roots, to denote the character of the subject of the verb. It is in the nature of this combination that we find the distinguishing feature of the Indo-Germanic stock of languages. At the same time we find (1) the "strengthening" of the vowel of the root, by the addition of the simplest vowel-sound *a*, to denote repeated or continuous as distinct from momentary action, (2) *reduplication*, originally producing the same effect, but afterwards, in a specialized form, denoting the continued result in the present of an act done in the past, (3) the *augment*, a particle, originally demonstrative in its nature, prefixed to a verb to denote that the action expressed by the verb took place at a time removed from the present, e.g., in the past. To the same stage (though possibly to a later part of it) belongs the further development of terminations, so as to mark an action as having a special reference to the subject, this produces what is in Greek conventionally called the middle voice, but what is really a reflexive formation. We may take as types of the words created during this stage such forms as *giva*, "give there," *g'e*, "he gives," *da-da-to*, "he is giving," *a-da-m*, "I gave," *da-da-mai*, "I give with a view to myself."

In a fourth stage we get the expansion of the root stems into a stem, occasioned apparently, in the first instance, by the increasing need of distinguishing the noun from the verb. The earliest method of forming a stem was by the addition of a "thematic vowel" *a* to the root, to convey the notion of a continuous action, thus from *kar*, "carry," came *ka-ka*, "carrying." Sometimes the vowel of the root was "strengthened" along with the addition of the thematic vowel, thus *lek*, "leave," *leka-ka*, "leaving." Afterwards other similar formative elements (or pronominal roots) such as *ta*, *na*, *ma*, *tra*, &c., were added to produce nominal stems of many various kinds. There is no reason to suppose that these were at first strictly differentiated in meaning, thus *par-va* is "filled," not "filling," but *va-va* may be taken either actively or passively, "the begotten" or "the begotten," and *tap-as-is* "the burning fever." Subsequently the instinct of language availed itself of variations in form to distinguish various relations, especially of gender. Again, when noun-stems came to be used, as the roots had previously been used, to form verbs by the addi-

* See Curtius, *Über das Spielzeug des A. Lauter*, Leipzig, 1864; Fick, *Die thematische Sprachlehre des Indogermanischen Europas*, Göttingen, 1878; *Vergleichende Wortbuch der Indogermanischen Sprachen*, 3d edition, Göttingen, 1876, where the list of common European words fills vol 1 pp 471-848. Compare *Gründzüge*, p 98.

* Scheler's doctrine of the "elemental" status of the *Zeiten* and the Celtic inflexions is not now generally accepted.

nre, nominative, and accusative are connected together much more closely than the remaining cases; they coincide in the neuter gender, and no one of them ever interchanges with or becomes equivalent to any one of the other group. On the other hand, in Sanskrit the ablative often coincides with the genitive, and the locative (in the dual) with the genitive or dative, while in Greek the instrumental is replaced by the dative, in Latin by the ablative, dative and genitive coincide in the Greek dual, dative and ablative in the Latin plural, and the locative always in Latin coincides in form with genitive, dative, or ablative. The vocative may be regarded as a relic of the preceding uninflected stage. The nominative and accusative are closely connected with theme formation, and seem to have been but a new development of the same principle. From a root *swap*, "sleep," came, as has been seen, at an early stage *swap na*, "sleeping," from *lar*, "make," came *lar ta*, "made." It was only an extension of the same method when the pronominal *sa* and *was* were added to the themes thus formed. Nominal inflexion was created as soon as it came to be recognized that the last additions were movable, and that the same stem might, according to circumstances, appear with one or the other or with neither. The fact that *sa* is found as the suffix of the nominative in some pronominals (*eg*, Sanskrit *aka-m = dyas*, *wa-m = rury*, *ka*) seems to point to a time when this was used as a determinative for nominative and accusative alike, but it soon became specialized as a characteristic of the latter. There is reason to believe that this process was facilitated, if not occasioned, by the use of the *m*-suffix to denote gender, or more strictly the absence of gender, in neuter nouns. It was only natural that the same suffix which distinguished the theme as a living being should be applied to mark it out as the subject or source of an action, while, conversely, that which denoted the absence of life should be used to mark the object. It is no improbable conjecture which finds in this accusative character of the sign of the neuter the explanation of the ordinary Greek idiom which constructs a neuter plural substantive with a singular verb, *ta zōa rēgē*, "the animals are running." Further, the wide and varied usages of the accusative case in Greek appears to point to a time when it was the only oblique case. At a later period the second group of cases made its appearance, this includes at least the genitive, ablative, dative, locative, instrumental, and vocative. Whether we are also to regard the various terminations which appear in some adverbs, which cannot be referred to any one of these, as originally case-inflections is a question not easy to determine, and one which is, after all, rather one of terminology than of any real importance. The theory of the purely local force of the cases, attractive as it is at first sight from its simplicity, and its apparent conformity with the sound theory which bids us, in dealing with language, proceed from the concrete to the abstract, and not *vice versa*, breaks down when we come to apply it in detail. For the genitive, at any rate, it is much safer to postulate an original adjectival force, a view borne out by striking similarity of formation in some instances (*eg*, *eg*, *θῆμα σοῦ*, the earlier form of the Homeric *θήματα*, the Attic *θήματα* and *θῆμα σοῦ*, "belonging to the people") and by numerous analogies from various languages. It has even been conjectured, though perhaps on inadequate grounds, that the genitive had originally the final *a*, which was dropped only when the sense of its origin became obscured. In the ablative we have apparently a use of the pronominal element *-a* corresponding to that of *-u* in the genitive, and originally in the nominative, the *a* being afterwards dropped, so that *uā a-s* = *uōs* is to *uā a-t* = *uōc(a)* as *ja = se* is to *ja-t* = *s d*. The syntactic force of the ablative may often be represented as adjectival; and the differentiation of the two cases may

will be a product of later times. The earliest forms of the other cases, the formation of which has not hitherto been satisfactorily explained, will be pointed out below.

In the seventh period assumed by Curtius we have the *Adv. Adv. petification* of some forms of particular themes with case- and pre-suffixes, which were no longer declined throughout, and thus gave rise to adverbs and prepositions. The adverbial force was undoubtedly the earlier, as we can see from indications in the Homeric poems, the prepositional force came later, first perhaps in connexion with verbs, and afterwards as governing cases. To the same period probably belongs the singularly interesting form of petrified cases presented by infinitives. These have long been recognized as cases of verbal nouns (*nomina actionis*) no longer inflected throughout. The agreement of the cognate languages in the use of this device for extending the range of language seems to be a sufficient indication that it had been introduced before the original unity broke up. At the same time the great variety of the forms actually selected by different languages as the basis of this construction is a clear proof that no well defined system of infinitives had then been brought into use.

Such were the stages by which, according to our greatest Recent living authority, that language grew which was destined to become the mother, not only of Greek and Latin, but of all of the most all the tongues in which human culture has found an utterance. It is by no means impossible to reconstruct it, at least in outline, as it must have been spoken before the original unity broke up. This task has been attempted, so far as its phonetic laws and inflexional forms are concerned, by Schleicher in his well-known *Compendium der vergleichenden Grammatik der Indogermanischen Sprachen* (3d edition, Weimar, 1871), and its vocabulary has been reconstructed by Riek in his *Vergleichendes Wörterbuch* already referred to. Schleicher indeed ventured to narrate a brief story in this primitive language (*Kuhn's Beilage*, vol. v pp 226 *eg*)¹. On particular points he may well have been mistaken. The tendency of modern philology is to admit within the period of the united national life a fuller development than that assumed by Schleicher. Several scholars, working along different lines of research and entirely independently, have established the great probability of a bifurcation of the gutturals, and it is by no means certain that the vowel system was not already becoming more rich and varied. We have probably to admit that dialectal differences already existed, such as could hardly have failed to arise, even before the nation broke up completely, so that it attained any considerable magnitude. And above all it must never be forgotten that we are dealing with the products of a period to which chronological limits cannot well be fixed, but which language gives us strong reasons to believe must have been at least as long as that to which the date of other branches of anthropology appear to point. It is impossible to be sure that all the elements which are introduced were ever strictly contemporaneous. Our review of the history of the language thus far is enough to show that one form may have begun to show traces of phonetic decay at a time when another form was not yet created. Hans M. Bréal (*Mélanges*, p 376) does well to warn us against the common error of philologists in endeavoring to get more out of the reconstructed "primitive speech" than the facts on which it is based will warrant. But used with discretion it affords a highly convenient means for stating the results to which the comparison of languages brings us.

For our present purpose it will be well to mark one intermediate stage between the source of the Greek lan-

¹ M. J. P. Postgate has published a similar composition (*Academy*, June 14, 1878), re-written by Mr. T. O. Shaw (ib., June 28) on the principles of Brugman and De Saussure.

The inflexion of verbs underwent far greater changes than that of nouns, after the separation, but mainly in the

way of a fuller development. In Latin, however, we must assume a very extensive replacing of earlier formations by those of later origin, for of many inflections which are shown to have been *Graeco Italic* by the *compendia* of Greek and Sanskrit, there are few if any traces to be found in Latin. The following principles of verbal flexion, the chief stages of whose development we have noticed above, had been established in the parent language —

- [illegible]

The researches of Curtius on the Græco-Italic vowel-system enable us to determine with some confidence the phonetic character assumed by these inflexions. We may give as the common possession, not *bharams*, &c., but

dhērōma, dhēraes, dhēraes,
dhērōmes, dhēraes, dhērōma,
 not *alvos*, &c, but
alvos, alvom, alvōd, alvōis, alvōi, alvōi, alvōi, alvōi.

Phonetic laws distinctive of Greek It was at this stage of inflexional development, and with a stock of roots and words which can still be ascertained with some approach to completeness, that the Greek language started its apparently unbroken series of changes which have

started on his separate career and commenced its independent history. The shape which it has assumed when it first becomes known to us from literary and epigraphic records is due to the action of its characteristic laws, some purely phonetic, and some due rather to the intellectual tendencies of those who used it. Of the phonetic laws four are especially distinctive —

- 1 *Loss of Sponants*—This is most extensive and important in its results; (y) has entirely disappeared from the written language, and its existence is only to be detected from isolated traces in Homer, and perhaps in some inscriptions where *f* is probably used to denote it, *ε* (*ew*) in the form of *f* is found on some of the older inscriptions, and its introduction into the text of Homer is often required by the metre, but it is unknown to the ordinary written language; *z* remains when final, and when in immediate contact with mutes, and also

when it has assimilated to itself another consonant, but before vowels it passes into the rough breathing, and between vowels it is as a rule entirely dropped. Justification of the effect of this loss of the spirants abound, as in example we may take the primitive *katasya*, which becomes *ufofofo*, *vevo*, *vevo*, and so on.

3. *Salutation of the Gutturals by Zayads*—It has been calculated that not less than one sixth of the roots originally containing λ or γ present π or β in Greek. Hence the undiphthongized pates (π), sing from that, "spick," $\pi\alpha\tau\epsilon\kappa\alpha$, in Greek be π and β in the other languages.
4. *Lightening of the λ -diphthongs*—Greek allows no consonants to end a word except π , ν , and ρ , and shows a marked preference for λ -diphthongs. Hence we often find one or more consonants dropped in Greek, and get a liquid flow to the language in which it has been used.
5. *Rapid Development of the Vowel System*—In this again Greek is the most advanced language, and is shared with it the original "lightening of the λ ," by its tendency to drop the λ in the beginning of a word, and to drop the λ in the middle of a word. In this language soon impaired the variety and expressiveness of its vocabulary, while Greek turned the full range undiminished, and the λ -diphthongs were used for the emphasis of the language, it added greatly to its expressiveness.
6. *Development of the Vowel System*—It is shown by many examples (*Comparative Phonology and Classical Scholarship*, p. 38) that few early distinctions in monophthongs were made in the other languages, which are expressed first of all in diphthongs in other languages.

We may notice here also the wide influences of *actarism*. This is not limited to Greek, as Schleicher showed in the essay which first set forth its importance properly, but it is more operative in Greek than in any language owing to the more complete disappearance of the *y*, which coalesces with some other consonant, usually a *d*, original, modified, or parasitic, to produce it. Thus *sad ya* became *ἑξά*, *vas ga* *ya*, *ἑξέ*, &c.

While these laws act naturally, and, so to say, mechanically, we must ascribe to the intellectual character of the action of the Greeks another marked feature of this language, the emotional development given to their verbal system. From wholly new tenses were created after the separation from the Italian stock—the future perfect, the compound pluperfect, two passive aorists, and two future passives. Besides, the whole system was worked out with wonderful richness of nuances. So that while an ordinary Latin verb has 14 possible inflections, corresponding Greek verbs have no less than 507. In some instances we can see the creative process still at work, as, *εἶναι*, in the case of the perfects in *-ειναι*, which are all but unknown to Homer.

*The Historic Stage of Greek*¹

The legend of the sons of Hellen, as we find it in Apollodorus, is of course entirely destitute of historical authority, but it serves as an indication of what the Greeks felt to be a natural division of their race, and from this point of view it is largely confirmed by language. The story runs that Hellen left his kingdom to Æolus his eldest son, while he sent forth Dorus and Xuthus, the father of Ion, to make conquests in different lands. We see from this that the Æolic dialect was regarded as the oldest representative of Hellenic speech, that the Dorian came next to it, and that the Ionian, out of which the Attic subsequently sprung, was regarded as belonging properly to a later period. On the whole this view is not misleading, but it requires some qualification. In the first place this division is more satisfactory for literature than for history, the names Æolie, Doric, Ionic, and Attic cover well enough the written language of Greece, but are hardly comprehensive enough for all the spoken dialects. These were literally innumerable,—we are told that the tiny island of Peopæthia had three dialects distinct,—and they shaded off one upon another by

¹ In dealing with this part of the subject no attempt has been made to record the ordinary forms of inflexion as given in grammars, a knowledge of which is assumed. For the Greek alphabet reference may be made to the article ALPHABET, vol. 1, especially pp 609-610. Much which is closely connected with the history of the language finds its place more properly under the head of Literature.

of sound which marks the ordinary course of language *ε γ, σ ρ* for *έ γ, ρ ρ* for *ρ ρ*, the same is possible in the instances where a simple vowel represents an initial diphthong, as in *αει, αερος, έδα, and ποει*, and in the tendency to allow *ε (η)* to substitute *αι*, *ε γ, βασιλεις, κλειθρον, λυει, ελεαον*, and the duals *σδεα, εσγειναι* to *σκηλ, εσγειν*. It is less easy to account for the change of *ην* (*ενν*)

Qualities of the Greek language

In the New Attic the Greek language may be said to have reached its zenith of grace, expressiveness, and symmetry, and hence this is the proper place for a few remarks on the qualities which have confessedly made the Greek language quite unrivalled as a means for the expression of human thought.

The Greeks felt themselves to be sharply marked off from the barbarians around them, and in consequence they loved to show that language to be contaminated by foreign influences. Latin was the language of the world, and the language of the East, and of the language, Greek has very few, and these almost invariably Hellenized in form. Hence the etymologists felt obliged to try to find the Greek source of every word. The etymologist of the present generation is not so much concerned with the regularity, and the orthography, as well established and rarely fluctuating. Then there is the phonology of the language. Dissimilation was everywhere, as added, *ἀντιπρόσωπον* for *ἀντιπρόσωπον*, *ἀντιπρόσωπον* for *ἀντιπρόσωπον*, and so on. The endings of the words are light, no hard consonant being undelated, except the liquids, *ρ* and *μ*, and the aspirant *ς*. The lightest of the vowels, *ε*, *ι*, *ο*, are far more common than the heavier *α*, *υ*, *ω*. The aspirant *ς* is not so common as it is sharply with Latin. The abundance of diphthongs is not so great in the modern pronunciation of Greek, gives a rich variety of sound.

needs supplying admirable means for the differentiation of mean-
 ings. The careful observation of accent, by the aid of and quite dis-
 tinct from the fixing marking of quantity, lent a vast modulation to
 the utterance, and the variety of the vocal inflections, which were
 procured from the ever becoming vociferous. The range of different
 forms at the disposal of poets and the freedom allowed in the order
 of words permitted the writer to choose the style thus almost effect-
 ually, and to give to his language the expression of his own feelings.
 The expressive of the language, the completeness of the verbal inflection,
 entitled various shades of meaning to be expressed with unavail-
 ing precision and to convey it. It is perhaps impossible to estimate with
 accuracy the number of words which the Greeks possessed, but it is
 known to us only from a literature which, in some of its most im-
 portant branches, has come down to us in a very fragmentary state.
 But such an estimation may be made from the fact that Herodotus
 mentions that the Greeks had more words than the Persians, and the
 power of word formation and composition to which this unavail-
 ing richness was largely due was no mechanical process. It sprang
 from the lively fancy of the most poetic of nations, — a fancy which
 gave itself scope in the significant individual names borne by the
 Greeks, and which, in the most striking manner, distinguished the
 and stereotyped appellative labels of the Romans, and in the Chris-
 tianistic and often open derisive appellations of plants and animals.
 Nor can we omit to mention, with respect to Aristotle, that he has
 exact and delicate use of the particles. Of all the qualities which
 make Greek really untranslatable, even into German, the only one
 of modern languages which approaches it in this respect, perhaps
 the only one, is the use of the particles. In the use of the particles
 speech not one of which can be neglected with impunity, while it
 is impossible to reproduce them all except at an expenditure of other
 means of expression which ruins the lightness and grace of the lan-
 guage. The particles, which are the life of the language, are those
 which, by the symmetry of form inseparably wedded to the artistic
 balance of thought, — a device which we found in no language which
 has not derived it directly or mediately from Greece, — belongs to the
 language of the poet, and which, in the hands of the philosopher, is
 for which formal syntactical ties had to discover a name and a class-
 ification, can only be understood aright if we look upon it as the
 attainment of a national life unswerving in the bold and virile firmness
 delighting in victory, and showing at its will a language still firm

From scholars are at one in regarding the modern pronunciation, advocated at the revival of learning by Reuchlin, as wholly misleading.

[illegible][illegible]

- 1 A pp. 98-122, ed. Abbotson; the latter has many losses.
- 2 A. 2sg. imperative of *ἐλθέω*, 'I come'; cf. *ἔλθ' ὦντα* with a participialitive, εὐχόμενος with the conjunctive, *ὦντα* with the present indicative.
- 3 A construction of verbs with cases unknown in Attic. e.g., γινώσκεις with accusative, προσκύνεις and προσφώνεις with dative, &c.
- 4 The extension of the genitive of the infinitive (*τοῖσι ποιεῖν*) beyond its original and natural limits.
- 5 The use of the conjunctive for the optative after past tenses, and the gradual diminution of the latter mood, which has wholly disappeared in modern Greek. (78 v. p. 38.)

Under the Greek empire, the language of literature was still based upon an artificial and often a lamentably inaccurate imitation of Attic, and an interesting parallel might be worked out in detail between the Greek and Latin literature of the latter period, and the literature of the Western Empire; the popular dialect went on its way, for the most part unrecognized in literature, but constantly exerting its effect upon the written language, and from time to time coming to the surface. The first of the modern Greek writers, the poet and dialectologist Theodoros Phokios (about 1100), a monk of Constantinople who lived under the emperor Manuel Comnenus (1143-1180), his language, though with some tinctures of the more ancient forms, is essentially modern Greek. The same is true of the Byzantine Samaras, a churchman of the fourteenth century, the author of a *Praxis*. In the 14th century we have the romances in verse, *Delhianos* and *Chrysanthos*, a work highly spoken of for imaginative power and free command of the language in its new form. The poems of the 15th century (see below) are still more modern. The poet *Rebours* (cent. xviii) justifies to show that the popular language never entirely ceased to be used as an organ of literary expression. An epoch in the history of modern Greek is marked by the struggle for national activity, which began in the 17th century (see below, 1748-1838). He made it his object to purify the popular dialect, not by an artificial reversion to the ancient Attic, but by a strenuous endeavour to preserve and to render current all classical forms not entirely extinct. He was not successful, but he did much to give the Greek people, often freshly converted for the purpose, Greece now can number poets, historians, scholars, and orators who bring forth from their native language no feeble echoes of the immortal words with which the ancients have delighted to speak.

Authorities.—For all that concerns the formation and history of Authors: the Greek language the writings of Professor G. Otfius of Leipzig are unrivalled in sound analysis of judgment and full mastery of all the details of the language. The chief are *Grammatica* and *Lexicon* of the most important authors. The chief are *Grammatica* and

Græcæque Rhetorica (5th edition, Leipzig, 1870, translated into English by A. S. Wilkins and E. B. England, 2 vols 1875-6), *Das Verbum der Griechischen Sprache* (vol. 1 2d edition, 1877, vol. 2 1876, English translation in one volume, 1880), *1 School Grammar* (8th English edition, 1876) and *Exposition of the facts of inflection and of syntax is* Schnerke's *Ästhetische Grammatik* (2d edition, 1871). For the Greek dialects, Albertus's *De Græcæ Linguae Dialectis* (2 vols 1869, 1848) remains the best work, but recent discovery has made it necessary to supplement it in many places, indispensable

material for this is furnished by the series of monographs in Curtius's *Studien zu Griechischen und Lateinischen Grammatik* (10 vols Leipzig, 1868-78) and in many method programmes and dissertations. Mr Murray's *Specimens of Greek Dialects* (Clarendon Press, 1876) contains similarly clear and useful introductions for junior students. Burgk's *Griechische Lautlehre* (Leipzig, 1876) contains much that is useful, but needs to be used with caution. For modern Greek the standard works are Smyth's *Classical Greek and Modern Greek* (Oxford, 1876), and Müller's *Grammatik der Griechischen Vulgar-Sprache* (Berlin, 1866) (A S W)

PART IV—GREEK LITERATURE

The history of Greek literature has had three great stages—the Old Literature, from the earliest times to 529 A.D., when the edict of Justinian closed the schools of pagan philosophy, the Byzantine Literature, from 529 A.D. to the taking of Constantinople by the Turks in 1453, and the Modern Literature, which may be said to have begun with the national poetry of Theodoros Prodromus in the 12th century.

SECTION I—THE OLD GREEK LITERATURE

The Old Literature, to 529 A.D., falls into three periods. I *The Early Literature*, to about 475 B.C. Epic, elegiac, iambic, and lyric poetry, the beginnings of literary prose. II *The Attic Literature*, 475-300 B.C. Tragic and comic drama, historical, oratorical, and philosophical prose. III *The Literature of the Decline*, 300 A.D. to 529 A.D., which may again be divided into (1) the Alexandrian period, 300-146 B.C., and (2) the Græco-Roman period, 146 B.C. to 529 A.D.

It is not the purpose of the present article to enter into details regarding particular works or the lives of their authors. These will be found in the separate articles devoted to the principal Greek writers. The object of the following pages will be to sketch the literary development as a whole, to show how its successive periods were related to each other, and to mark the dominant characteristics of each.

I *The Early Literature*

A process of natural growth may be traced through all the best work of the Greek genius. The Greeks were not literary imitators of foreign models, the forms of poetry and prose in which they attained to such unequalled excellence were first developed by themselves. Their literature had its roots in their political and social life, it is the spontaneous expression of that life in youth, maturity, and decay, and the order in which its several fruits are produced is not the result of accident or caprice. The science of its seasons is as much the result of natural laws as the sequence of spring, summer, and autumn. Further, the old Greek literature has a striking completeness, due to the fact that each great branch of the Hellenic race bore a characteristic part in its development. Ionians, Æolians, Dorians, in turn contributed their share. Each dialect corresponded to a certain aspect of Hellenic life and character. Each found its appropriate work.

The
dialects

The Ionians on the coast of Asia Minor—a lively and genial people, delighting in adventure, and keenly sensitive to everything bright and joyous—created artistic epic poetry out of the lays in which Æolic minstrelsy sang of the old Achæan wars. And among the Ionians arose elegiac poetry, the first variation on the epic type. These found a fitting instrument in the harmonious Ionic dialect, the flexible utterance of a quick and versatile intelligence. The Æolians of Lesbos next created the lyric of personal passion, in which the traits of their race—its chivalrous pride, its bold but sensuous fancy—found a fitting voice in the fiery strength and tenderness of Æolic speech. The Dorians of

the Peloponnese, sturdy, and Magna Græcia then perfected the choral lyric for festivals and religious worship, and here again an earnest faith, a strong pride in Dorian usage and customs, had an apt interpreter in the massive and vigorous Doric. Finally, the Attic branch of the Ionian stock produced the drama, blending elements of all the other kinds, and developed an artistic literary prose in history, oratory, and philosophy. It is in the Attic literature that the Greek mind receives its most complete interpretation.

A natural affinity was felt to exist between each dialect and that species of composition for which it had been specially used. Hence the dialect of the Ionian epic poets would be adopted with more or less thoroughness even by epic and elegiac poets who were not Ionians. Thus the Attic and Æolic dialects in epic, the Dorian Theognis in elegy, though not without alloy. Similarly, the Dorian Theocritus wrote love songs in Æolic. The Attic Theophrastus wrote comic poems for his marching songs. All the faculties and tones of the language were thus gradually brought out by the co-operation of the dialects. Old Greek literature has an essential unity—the unity of a living organism, and this unity comprehends a number of distinct types, each of which is complete in its own kind.

Extant Greek literature begins with the Homæic poems. These are works of art which imply a long period of antecedent poetical cultivation. Of the pre-Homæic poetry we have no remains, and very little knowledge. Such glimpses as we get of it connect it with two different stages in the religion of the prehistoric Hellenes. The first of these stages is that in which the agonies or forms of external nature were personified indeed, yet with the consciousness that the personal names were only symbols. Some very ancient Greek songs of which mention is made may have belonged to this stage—as the songs of Linus, Ilium, and Hylas. Linus, the fair youth killed by dogs, seems to be the spring passing away before Sirius. Such songs have been aptly called "songs of the seasons." The second stage is that in which the Hellenes have now definitively personified the powers which they worship. Apollo, Demeter, Dionysus, Cybele, have now become to them beings with clearly conceived attributes. To this second stage belong the hymns connected with the names of the legendary lords, heroes, such as Orpheus, Musæus, Erichonius, who are themselves associated with the worship of the Proian Muses and the Attic ritual of Demeter. The songs of this early sacred poetry are not only "Thæanum"—*θεῶν*, on the borders of northern Greece—but also "Phrygian" and "Carian." It belongs, that is, presumably to an age when the ancestors of the Hellenes had left the Indo-European home in central Asia, but had not yet taken full possession of the lands which were afterwards Hellenic. Some of their tribes were still in Asia, others were settling on the islands of the Ægean, others were passing through the lands on its northern shore. If there was a period when the Greeks possessed no poetry but hymns forming part of a religious ritual, it may be conjectured that it was not of long duration. Already in the *Iliad* a secular character belongs to the

marriage hymn and to the dirgo for the dead, which in ancient India were chanted by the priest. The bent of the Greeks was to claim poetry and music as public joys, they would not long have suffered them to remain sacerdotal mysteries. And among the earliest themes on which the lay artist in poetry was employed was probably war-ballads, sung by minstrels in the houses of the chiefs whose ancestors they celebrated.

Epos Such war-ballads were the material from which the earliest epic poetry of Greece was constructed. By an "epic" poem the Greeks meant a narrative of heroic action in hexameter verse. The term *epos* meant at first simply "verses". It acquired its special meaning only when *epic*, lyric songs set to music, came to be distinguished from *epic*, verses not set to music, but merely recited. Epic poetry is the only kind of extant Greek poetry which is older than about 700 B.C. The early epos of Greece is represented by the *Iliad* and the *Odyssey*, Hesiod, and the Homeric hymns, also by some fragments of the "Cyclic" poets.

The *Iliad*
and
the
Odyssey

After the Dorian conquest of the Peloponnesus, the Achaean emigrants who settled in the north-west of Asia Minor brought with them the warlike legends of their chiefs, the Achaean princes of old. These legends lived in the ballads of the Achaean minstrels, and from them passed southward into Ionia, where the Ionian poets gradually shaped them into higher artistic forms. Among the seven places which claimed to be the birthplace of Homer, that which has the best title is Smyrna. Homer himself is called "son of Meles"—the stream which flowed through old Smyrna, on the border between Aolia and Ionia. The tradition is significant in regard to the origin and character of the *Iliad*, for in the *Iliad* we have Achaean ballads worked up by Ionian art. A preponderance of evidence is in favour of the view that the *Odyssey* alone, at least in its earliest form, was composed on the Ionian coast of Asia Minor. According to the Spartan account, Lycurgus was the first to bring to Greece a complete copy of the Homeric poems, which he had obtained from the Caeophylidae, a clan or guild of poets in Samos. A better authenticated tradition connects Athens with early attempts to preserve the chief poetical treasure of the nation. Pisistratus is said to have charged some learned men with the task of collecting all "the poems of Homer", but it is difficult to decide how much was comprehended under this last phrase, or whether the province of the commission went beyond the mere task of collecting. Nor can it be determined what exactly it was that Solon and Hipparchus respectively did for the Homeric poems. Solon, it has been thought, enacted that the poems should be recited from an authorized text (*ἐξ ἀποδείξεως*), Hipparchus, that they should be recited in a regular order (*ἐξ ἀποδείξεως*). At any rate, we know that in the 6th century B.C. a recitation of the poems of Homer was one of the established competitions at the Panathenaea, held once in four years. The reciter was called a *rhapsoδιστής*,—properly one who weaves a long, smoothly-flowing chant, then an epic poet who chants his own or another's poem. The rhapsodist did not, like the early minstrel, use the accompaniment of the harp, he gave the verses in a flowing recitative, bearing in his hand a branch of laurel, the symbol of Apollo's inspiration. In the 5th century B.C. we find that various Greek cities had their own editions (*αἱ ἰδιαιτέρας ἀποδείξεις*) of the poems, for recitation at their festivals. Among these were the editions of Massilia, of Chios, and of Argos. There were also editions bearing the name of the individual editor (*αἱ κατ' ἀνδρῶν*)—the best known being that which Aristotle prepared for Alexander. The recension of the poems by Aristarchus (156 B.C.) became the standard one, and is probably that on which the existing text is based. The oldest Homeric MS. extant, Vaticanus A. of the *Iliad*,

is of the 10th century, the first printed edition of Homer was that edited by the Byzantine Demetrius Chalcandyles (Florence, 1488). The first Aldine edition appeared twelve years later.

The ancient Greeks were almost unanimous in believing that the *Iliad* and the *Odyssey* to be the work of one man, Homer, to whom they also ascribed some extant hymns, and probably much more besides. Aristotle and Aristarchus seem to have put Homer's date about 1044 B.C., Herodotus about 850 B.C. It was not till about 170 B.C. that the grammarians Hellanicus and Xenon put forward the view that Homer was the author of the *Iliad*, but not of the *Odyssey*. Those who followed them in assigning different authors to the two poems were called the Separatists (or *Chorizontes*). Aristarchus combated "the paradox of Xenon," and it does not seem to have had much acceptance in antiquity. Vico, a Neapolitan (1668-1744), seems to have been the first modern to suggest the composite authorship and oral tradition of the Homeric poems, but this was a pure conjecture in support of his theory that the names of ancient lawgivers and poets are often mere symbols. If A. Wolf, in the *Prolegomena* to his edition (1795), was the founder of a scientific scepticism. The *Iliad*, he said (for he recognized the comparative unity and consistency of the *Odyssey*), was pieced together from many small written poems by various hands, and was first committed to writing in the time of Pisistratus. This view was in harmony with the tone of German criticism at the time, it was welcomed as a new testimony to the superiority of popular poetry, springing from fresh natural sources, to elaborate works of art, and it at once found enthusiastic adherents. For the cause of Homeric controversy since Wolf the reader is referred to the article HOMER. The general result has been, not to prove any piece of authorship, but rather to establish certain general propositions, and so far to limit the question. It is now generally admitted that the *Iliad* and the *Odyssey*, whatever their absolute or relative ages, must at least be regarded as belonging to the maturity of a poetical school in Ionia, which had gradually created an epic style. Next, it can no longer be doubted that the *Iliad* contains elements of various age and origin, the form and the matter alike show this, though we cannot with certainty point to any one group of these elements as the original nucleus around which our *Iliad* grew. Comparing the *Odyssey* with the *Iliad*, we perceive greater unity of design and of colouring, and indications of a somewhat later time, but not even here can we affirm that the poem, as we have it, is the work of one man.

The Ionian school of epos produced a number of poems which founded on the legends of the Trojan war, and intended as introductions or continuations to the *Iliad* and the *Odyssey*. The grammarian Proclus (140 A.D.) has preserved the names and subjects of some of these, but the fragments are very scanty. The *Nostos* or *Homecoming Voyages*, by Agias of Træzen, filled up the gap of ten years between the *Iliad* and the *Odyssey*, the *Lay of Telegonus*, by Euphronius of Cyrene, continued the story of the *Odyssey* to the death of Odysseus by the hand of Telegonus, the son whom Circe bore to him. Similarly the *Cyprian Lay*, by Sappho of Cyprus, was introductory to the *Iliad*, the *Æthiops* and the *Sack of Troy*, by Arctinus of Miletus, and the *Little Iliad*, by Lesches of Mitylene, were supplementary to it. These and many other names of lost epos—some taken also from the Theban myths—serve to show how prolific was that epic school of which only two great examples remain. The name of *epic cycle* was properly applied to a prose compilation of abstracts from these epos, pieced together in the order of the events. The compilers were called "epic" writers, and the term has now been transferred to the epic poets whom they used.

Hesiodic The epic poetry of Ionia celebrated the great deeds of heroes in the old days. But in Greece proper there arose another school of epics, which busied itself with religious lore and ethical precepts, especially in relation to the rural life of Boeotia. This school is represented by the name of Hesiod. The legend speaks of him as vanquishing Homer in a poetical contest at Chalcis in Euboea, and it expresses the fact that, to the old Greek mind, these two names stood for two contrasted epic types. Nothing is certainly known of his date, except that it must have been subsequent to the maturity of Ionian epics. He is conceptually placed about 850-800 B.C., but some would refer him to the early part of the 7th century B.C. His home was, at Ascra, a village in a valley under Helicon, whence his father had migrated from Cyme in *Eolus* on the coast of Asia Minor. In Hesiod's *Works and Days* we have the earliest example of a didactic poem. The seasons and the labours of the Boeotian farmer are followed by a list of the days which are lucky or unlucky for work. The *Theogony*, or "Origin of the Gods," describes first how the visible order of nature arose out of chaos, next, how the gods were born. Though it never possessed the character of a sacred book, it remained a standard authority on the genealogies of the gods. So far as a corrupt and confused text warrants a judgment, the poet was piecing together—not always intelligently—the fragments of a very old cosmogonic system, using for this purpose both the hymns preserved in the temples and the myths which lived in folk-lore. The epic lay in 480 lines called the *Shield of Heracles*—partly imitated from the 18th book of the *Iliad*—is the work of an author or authors later than Hesiod. In the Hesiodic poetry, as represented by the *Works and Days* and the *Theogony*, we see the influence of the temple at Delphi. Hesiod recognizes the existence of *daemones*—spirits of the departed who haunt the earth as the inviolable guardians of justice, and he connects the office of the poet with that of the prophet. The poet is one whom the gods have authorized to impress doctrine and practical duties on men. A religious purpose was essentially characteristic of the Hesiodic school. Its poets treated the old legends as tales of a sacred history, and not merely, in the Ionian manner, as subjects of idealizing art. Such titles as the *Mosses of Cherson* and the *Lay of Metampus*, the semi-lost poems of the Hesiodic school—illustrate its ethical and its mystic tendencies.

The Homeric Hymns The *Homeric Hymns* form a collection of thirty-three pieces, some of them very short, in hexameter verse. Their traditional title is—*Hymns* or *Praises of Homer and the Homers*. The second of the alternative designations is the true one. The pieces are not "hymns" used in formal worship, but "praises" or prefatory addresses (*epoioia*) with which the rhapsodists entered in their recitations of epic poetry. The "praise" might be addressed to the presiding god of the festival, or to any local deity whom the reciter wished to honour. The pieces range in date perhaps from 750 to 600 B.C., and it is probable that the collection was formed in Attica, for the use of rhapsodists. The style is that of the Ionian or Homeric epics, but there are also several traces of the Hesiodic or Boeotian school. The five principal "hymns" are those (1) to the Delian Apollo, 1-177, (2) to the Pythian Apollo, 178 to end; (3) to Hermes, 1, (4) to Aphrodite, 1, and (5) to Demeter, 1. The hymn to the Delian Apollo, quoted by Theocritus (in 104) as Homer's, is of peculiar interest on account of the lines describing the Ionian festival at Delos. Two celebrated pieces of a sportive kind passed under Homer's name. The *Margites*—a comic poem on one "who knew many things but knew them all badly"—is regarded by Aristotle as the earliest germ of comedy, and was possibly as old as 700 B.C. Only a few lines remain. The *Battle of the Frogs and Mice* probably belongs to the decline of

Greek literature, perhaps to the 2d century B.C. About 300 verses, of it are extant.

In the *Iliad* and the *Odyssey* the personal opinions or sympathies of the poet may sometimes be conjectured, but they are not declared, or even hinted. Hesiod, indeed, sometimes gives us a glimpse of his own troubles or views. Yet Hesiod is, on the whole, essentially a prophet. The message which he delivers is not from himself, the truths which he imparts have not been discovered by his own senses. He is the mouthpiece of the Delphian Apollo. Personal opinion and feeling may tinge his utterance, but they do not determine its general complexion. The egoism is a single thread, it is not the basis of the poem. Epic poetry was in Greece the foundation of all other poetry, for many centuries no other kind was generally cultivated, no other could speak to the whole people. Politically, the age was monarchical or aristocratic, intellectually, it was too simple for the analysis of thought or emotion. Kings and princes loved to hear of the great deeds of their ancestors, common men loved to hear of them too, for they had no other interest. The mind of Greece found no subject of contemplation so attractive as the walk to the past of the race, or so useful as that lore which experience and tradition had bequeathed. But in the course of the 8th century B.C. the role of hereditary princes began to disappear. Monarchy gave place to oligarchy, and this—often after the intermediate phase of a tyranny—to democracy. Such a change was necessarily favourable to the growth of education. The private citizen is no longer a mere ephebe, the *Homotrochos*, a unit in the dim multitude of the king-ruled folk, he gains more power of independent action, his mental horizon is widened, his life becomes fuller and more interesting. He begins to feel the need of expressing the thoughts and feelings that are stirred in him. But as yet a prose literature does not exist, the new thoughts, like the old heroic stories, must still be told in verse. The forms of verse created by this need were the Elegiac and the Iambic.

The elegiac metron is, in form, a simple variation on the heroic epic metre, obtained by docking the second of two hexameters so as to make it a verse of five feet or measures. But the poetical capabilities of the elegiac couplet are of a wholly different kind from those of heroic verse. *Alone* seems to be the Greek form of a name given by the Carians and Lydians to a lament for the dead. This was accompanied by the soft music of the Lydian flute, which continued to be associated with Greek elegy. The non-Hellenic origin of elegy is indicated by this very fact. The flute was to the Greeks an Asiatic instrument,—string instruments were those which they made their own,—and it would hardly have been wedded by them to a species of poetry which had arisen among themselves. The early elegiac poetry of Greece was by no means confined to mourning for the dead. War, love, politics, proverbial philosophy, were in turn its themes, its dole, in fact, with the chief interest of the poet and his friends, whatever that might be at the time. It is the direct expression of the poet's own thoughts, addressed to a sympathizing society. This is its first characteristic. The second is that, even when most pathetic or most spirited, it still preserves, on the whole, the tone of conversation or of narrative. Greek elegy stops short of lyric passion. English elegy, whether funeral as in Dryden and Pope, or reflective as in Gray, is usually true to the same normal type. Roman elegy is not equally true to it, but sometimes tends to trench on the lyric province. For Roman elegy is mainly amatory or sentimental, and its meters imitated, as a rule, not the early Greek elegiacs, not Tyrtæus or Theognis, but the later Alexandrian elegists, such as Callimachus or Philetas. Catullus introduced the metre to Latin literature, and used it with more fidelity than his followers to its genuine Greek inspiration.

Iambic verse Elegy, as we have seen, was the first slight deviation from epic. But almost at the same time another species arose which had nothing in common with epics, either in form or in spirit. This was the iambic. The word *iambos* (*iupia*, to dart or shoot) was used in reference to the licensed raillery at the festivals of Demeter, it was the maiden Iambe, the myth said, who drew the first smile from the mourning goddess. The iambic metre was at first used for satire, and it was in this strain that it was chiefly employed by its earliest master of note, Archilochus of Paros (670 B.C.). But it was adapted to the expression generally of any pointed thought. Thus it was suitable to fables. Elegiac and iambic poetry both belong to the borderland between epic and lyric. While, however, elegy stands nearest to epics, iambic stands nearest to the lyric. Iambic poetry can express the personal feeling of the poet with greater intensity than elegy does, on the other hand, it has not the lyric flexibility, self-abandonment, or glow. As we see in the case of Solon, iambic verse could serve for the expression of that deeper thought, that more inward self-communing, for which the elegiac form would have been inappropriate.

But these two forms of poetry, both Ionian, the elegiac and the iambic, belong essentially to the same stage of the literature. They stand between the Ionian epics and the lyric poetry of the *Æolians* and *Dorians*. The earliest of the Greek elegists, Callinus and Tyrtaeus, use elegy to arouse a warlike spirit in smiting hosts. Archilochus too wrote warlike elegy, but used it also in other strains, as in lament for the dead. The elegy of Mimnermus is the plaintive fainioll of an ease-loving Ionian to the days of Ionian freedom. In Solon elegy takes a higher range, it becomes political and ethical. Theognis represents the mature union of politics with a proverbial philosophy. Xenophanes gives a philosophic strain to elegy. With Simonides of Ceos it reverts, in an exquisite form, to its earliest destination, and becomes the vehicle of epitaph on those who fell in the Persian wars. Iambic verse was used by Simonides of Amorgos, as by Archilochus, for satire,—but satire directed against classes rather than persons. Solon's iambics, so far preserve the old associations of the metre that they represent the polemical or controversial side of his political poetry. Hipponax of Ephesus was another iambic satirist,—using the "scazon" or "limping" verse, produced by substituting a spondee for an iambus in the last place. But it was not until the rise of the Attic drama that the full capabilities of iambic verse were seen.

Lyric poetry

The lyric poetry of early Greece may be regarded as the final form of that effort at self-expression which in the elegiac and iambic is still incomplete. The lyric expression is deeper and more impassioned. Its intimate union with music and with the rhythmical movement of the dance gives to it more of an ideal character. At the same time the continuity of the music points pauses to the voice,—pauses necessary as reliefs after a climax. Before lyric poetry could be effective, it was necessary that some progress should have been made in the art of music. The instrument used by the Greeks to accompany the voice was the four-stringed lyre, and the first great epoch in Greek music was when Terpander of Lesbos (660 B.C.), by adding three strings, gave the lyre the compass of the octave. Further improvements are ascribed to Olympus and Thaletas. By 600 B.C. Greek music had probably acquired all the powers of expression which the lyric poet could demand. The period of Greek lyric poetry may be roughly defined as from 670 to 440 B.C. Two different parts in its development were taken by the *Æolians* and the *Dorians*.

Æolian school

The lyric poetry of the *Æolians*—especially of Lesbos—was essentially the utterance of personal feeling, and was usually intended for a single voice, not for a chorus.

Lesbos, in the 7th century B.C., had attained some moral and *comparative* importance. But the state of slavery and democracy was active, the Lesbian public was often driven by revolution to exchange their luxurious home-life for the hardships of exile. It was such a life of contrasts and events, working on a sensuous and buoy temperament, that is reflected in the fragments of *Alcæus*. In these glimpses of war and love, of anxiety for the storm-tossed state and of careless festivity, there is much of the cavalier spirit, if Archilochus is in certain aspects a Greek Byron, *Alcæus* might be compared to Lovelace. The other great representative of the *Æolian* lyric is Sappho, the only woman of Greek race who is known to have possessed poetic genius of the first order. Intensity and melody are the characteristics of the fragments that remain to us. Probably no poet ever surpassed Sappho as an interpreter of passion in exquisitely subtle harmonies of form and sound. Anacreon of Teos, in Ionia, may be classed with the *Æolian* lyricists in so far as the matter and form of his work resembled theirs, though the dialect in which he wrote was mainly the Ionian. A few fragments remain from his hymns to the gods, from love-poems and festive songs. The collection of sixty short pieces, which passes current under his name dates only from the 10th century. The short poems which it comprises are of various age and authorship,—all of them probably of the Christian era. They have not the pure style, the florid grace, or the sweetness of the classical fragments, but the verses, though somewhat mechanical, are often pretty.

The *Dorian* lyric poetry, in contrast with the *Æolian*, had *Demus* more of a public than of a personal character, and was for school the most part choral. Hymns or choruses for the public worship of the gods, and odes to be sung at festivals on occasions of public interest, were its characteristic forms. Its central inspiration was the pride of the Dorians in the Dorian past, in their traditions of worship, government, and social usage. The history of the *Dorian* lyric poetry does not present us with vivid expressions of personal character, like those of *Alcæus* and Sappho, but rather with a series of artists whose names are associated with improvements of form. Thus *Alman* (860 B.C.) is said to have introduced the balanced movement of strophe and antistrophe. *Stasichorus*, of Himera in Sicily, added the *epode*, sung by the chorus while stationary after these movements. *Arion* gave a finished form to the choral hymn ("dithyramb") in honour of Dionysus, and organized the "cyclic" or *circular* chorus which sang it at the altar.

The culmination of the lyric poetry is marked by two *Simonides* great names, *Simonides* and *Pindar*. *Simonides* was an *Æolian* of the island of Ceos, but his lyrics belonged by form to the choral *Dorian* school. Many of his subjects were taken from the events of the Persian war; his epitaphs on those who fell at Thermopylæ and Salamis were celebrated. In him the lyric art of the Dorians is interpreted by Ionian genius, and Athens—where part of his life was passed—is the point at which they meet. *Simonides* is the first Greek lyric whose significance is not merely *Æolian* or *Dorian* but *Panhellenic*. The same character belongs even more completely to his younger contemporary *Pindar* was born in Boeotia of a Dorian stock, thus, as *Ionian* and *Dorian* elements meet in *Simonides*, so *Dorian* and *Æolian* elements meet in *Pindar*. *Simonides* was perhaps the most tender and most exquisite of the lyric poets. *Pindar* was the boldest, the most fervid, and the most sublime. His extant fragments represent almost every branch of the lyric art. But he is known to us mainly by forty-four *Epynia*, or odes of victory, for the Olympian, Pythian, Nemean, and Isthmian festivals. The general characteristic of the treatment is that the particular victory is made the occasion of introducing heroic legends connected

with the family or city of the victor, and of insinuating the moral lessons which they teach. No Greek lyric poetry can be completely appreciated apart from the music, now lost, to which it was set. Pindar's odes were, further, essentially occasional poems, they abound in allusions of which the effect is partly or wholly lost on us, and the glories which they celebrate belong to a life which we can but imperfectly realize. Of all the great Greek poets, Pindar is perhaps the one to whom it is hardest for us to do justice, yet we can at least recognize his splendour of imagination, his strong rapidity, and his soaring flight.

II. The Attic Literature

The Ionians of Asia Minor, the Æolians, and the Dorians had now performed their special parts in the development of Greek literature. Epic poetry had interpreted the heroic legends of valiant deeds done by Zeus-nourished kings and chiefs. Then, as the individual life became more and more, elegiac and iambic poetry had become the social expression of that life in all its varied interests and feelings. Lastly, lyric poetry had arisen to satisfy a twofold need—to be the more intense utterance of personal emotion, or to give choral voice, at stirring moments, to the faith or fame, the triumph or the sorrow, of a city or a race. A new form of poetry was now to be created, with elements borrowed from all the rest. And this was to be achieved by the people of Attica, in whose character and language the distinctive traits of an Ionian descent were tempered with some of the best qualities of the Dorian stock.

The drama arose from the festivals of Dionysus, the god of wine, which were held at intervals from the beginning of winter to the beginning of spring. A troop of rustic worshippers would gather around the altar of the god, and sing a hymn in his honour, telling of his victories or sufferings in his progress over the earth. "Tragedy" meant "the goat-song," a goat being sacrificed to Dionysus before the hymn was sung. "Comedy," "the village-song," is the same hymn regarded as an occasion for rustic jest. Then the leader of the chorus would assume the part of a messenger from Dionysus, or even that of the god himself, and recite an adventure to the worshippers, who made choral response. The next step was to arrange a dialogue between the leader (*coryphæus*) and one chosen member of the chorus, hence called "the answerer" (*hypocritæ*), afterwards the ordinary word for "actor." This last improvement is ascribed to the Attic Thespis (about 536 B.C.). The elements of drama were now ready. The choral hymn to Dionysus (the "dithyramb") had received an artistic form from the Dorians, dialogue, though only between the leader of the chorus and a single actor, and been introduced in Attica. Phrynichus, an Athenian, celebrated in the manner some events of the Persian war, but in his "drama" there was still only one actor.

Æschylus (born 525 B.C.) became the real founder of tragedy by introducing a second actor, and thus rendering the dialogue independent of the chorus. At the same time the choral song—hitherto the principal part of the performance—became subordinate to the dialogue, and drama was mature. Æschylus is also said to have made various improvements of detail in costume and the like, and it was early in his career that the theatre of Dionysus under the acropolis was commenced—the first permanent home of Greek drama, in place of the temporary wooden platforms which had hitherto been used. The system of the "trilogy" and the "tetralogy" is further ascribed to Æschylus,—the "trilogy" being properly a series of three tragedies connected in subject, such as the *Agamemnon*, *Choephori*, *Eumenides*, which together form the *Orestes*, or Story of Orestes. The "tetralogy" is such a triad with a "satyric drama" added—that is, a drama in which "satyrs,"

the grotesque woodland beings who attended on Dionysus, formed the chorus, as in the earlier dithyramb from which drama sprang. The *Cyclops* of Euripides is a satyric drama. In the seven tragedies which alone remain of the seventy which Æschylus is said to have composed, the forms of kings and heroes have a grandeur which is truly Homeric, there is a spirit of Panhellenic patriotism such as the Persian war in which he fought might well quicken in a soldier-poet, and, pervading all, there is a strain of speculative thought which seeks to reconcile the apparent conflicts between the gods of heaven and of the underworld by the doctrine that both alike, constrained by necessity, are working out the law of righteousness. Sophocles, who was born thirty years after Sophocles (495 B.C.), is the most perfect artist of the ancient drama. No one before or after him gave to Greek tragedy so high a degree of ideal beauty, or appreciated so fully the possibilities and limitations of its sphere. He excels especially in drawing character, his *Antigone*, his *Oedipus*, his *Æschylus*—indeed, all the chief persons of his dramas—are typical studies in the great primary emotions of human nature. He gave a freer scope to tragic dialogue by adding a third actor, and in one of his later plays, the *Æschylus* at *Colonus*, a fourth actor is required. From the time when he won the tragic prize against Æschylus in 468 to his death in 405 B.C. he was the favourite dramatist of Athens, and for us he is not only a great dramatist, but also the most spiritual representative of the age of Pericles. The distinctive interest of Euripides is of another kind. He was only fifteen years younger than Sophocles, but when he entered on his poetical career, the old usages of tragedy were already failing. Euripides marks a period of transition in the tragic art, and, in fact, the mediocrity between the classical and the romantic drama. The myths and traditions with which the elder dramatists had dealt no longer commanded an unquestioning faith. Euripides himself was imbued with the new intellectual scepticism of the day, and the speculative views which were conflicting in his own mind are reflected in his plays. He had much picturesque and pathetic power, he was a master of expression, and he showed ingenuity in devising fresh resources for tragedy—especially in his management of the choral songs. Æschylus is Panhellenic, Sophocles is Athenian, Euripides is cosmopolitan. He stands nearer to the modern world than either of his predecessors, and though with him Attic tragedy loses its highest beauty, it acquires new elements of familiar human interest.

In Attica, as in England, a period of rather less than fifty years sufficed for the complete development of the tragic art. The two distinctive characteristics of Athenian drama are its originality and its abundance. The Greeks of Attica were not the only inventors of drama, but they were the first people who made drama a complete work of art. And the great tragic poets of Attica were remarkably prolific. Sophocles was the reputed author of 70 tragedies, Sophocles of 113, Euripides of 92, and there were others whose productiveness was equally great.

Comedy represented the lighter side, as tragedy the Comedy grave side, of the Dionysiac worship, it was the joy of spring following the gloom of winter. The process of growth was nearly the same as in tragedy, but the Dorians, not the Ionians of Attica, were the first who added dialogue to the comic chorus. Sæmonax, a Dorian of Megara, exhibited about 680 B.C. pieces of the kind known as "Megarian farces." The more artistic form of comedy seems, however, to have been developed in Attica. The greatest names before Aristophanes are Cratinus and Eupolis, but from about 470 B.C. there seems to have been a continuous succession of comic dramatists. Aristophanes came forward as a comic poet in 427 B.C., and retained his popularity for about forty years. He presents

a perhaps unique union of bold fancy, exquisite humour, critical acumen, and lyrical power. His slender extant comedies may be divided into three groups, according as the licence of political satire becomes more and more restricted. In the *Alkistades*, *Knights*, *Clouds*, *Wasps*, and *Peace* (425-421) the poet uses unrestrained freedom. In the *Birds*, *Lysistrata*, *Thesmophoriazuse*, and *Plutus* (414-405) a greater reserve may be perceived. Lastly, in the *Eubulissus* and the *Plutus* (393-388) personal satire is almost wholly avoided. The same general tendency continued. The so-called "Middle Comedy" (380-320) represents the transition from the Old Comedy, or political satire, to satire of a literary or social nature. The "New Comedy" (320-260) resembled the modern "comedy of manners." These successive periods cannot be sharply or precisely marked off. The change which gradually passed over the comic drama was simply the reflection of the change which passed over the political and social life of Athens. The Old Comedy, as we see it in the earlier plays of Aristophanes, was probably the most powerful engine of public criticism that ever existed in any community. Unsparring personality was its essence. The comic poet took this recognized right on an occasion at once festive and sacred, in a society where every man of any note was known by name and sight to the rest. The same thousands who heard a policy or a character denounced or lauded in the theatre might be required to pass sentence on it in the popular assembly, or in the courts of law.

Literary
prose

The development of Greek poetry had been completed before a prose literature had begun to exist. The earliest name in extant Greek prose literature is that of Herodotus, and, when he wrote, the Attic drama had already passed its prime. There had been, indeed, writers of prose before Herodotus, but these had not been, in the proper sense of the term, a prose literature. The causes of this comparatively late origin of Greek literary prose are independent of the question as to the time at which the art of writing began to be generally used for literary purposes. Epic poetry exercised for a very long period a sovereign spell over the Greek mind. In it was deposited all that the race possessed of history, theology, philosophy, oratory. Even after an age of reflection had begun, elegant poetry, the first offshoot of epic, was, with laudable verse, the vehicle of much which among other races would have been committed to prose. The basis of Greek culture was essentially poetical. A political cause worked in the same direction. In the Eastern monarchies the king was the centre of all, and the royal records afforded the elements of history from a remote date. The Greek nation was broken up into small states, each busied with its own affairs and its own men. It was the collision between the Greek and the barbarian world which first provided a natural subject for a Greek historian. The work of Herodotus, in its relation to Greek prose, is so far analogous to the *Iliad* in its relation to Greek poetry, that it is the earliest work of art, and that it bears a Panhellenic stamp.

Early
prose
writers

The sense and the degree in which Herodotus was original may be inferred from what is known of earlier prose-writers. For about a century before Herodotus there had been a series of writers in philosophy, mythology, geography, and history. The earliest, or among the earliest, of the philosophical writers were Pherecydes of Syros (550 B.C.) and the Ionian Anaximander and Anaximenes. The Ionian writers, especially called *logographers*, "writers in prose" (as distinguished from *poetæ*, makers of verse), were those who compiled the myths, especially in genealogies, or who described foreign countries, their physical features, usages, and traditions. Hecataeus of Miletus (500 B.C.) is the best-known representative of the *logographers* in both these branches. Hel-

lanicus of Mitylene (450 B.C.), among whose works was a history of Attica, appears to have made a nearer approach to the character of a systematic historian.

Herodotus was born in 484 B.C., and his history was probably not completed before the beginning of the Peloponnesian War (431 B.C.). His subject is the struggle between Greece and Asia, which he deduces from the legendary rape of the Argive Io by Poseidonius, and traces down to the final victory of the Greeks over the invading host of Xerxes. His literary kinship with the historical or geographical writers who had preceded him is seen mainly in two things. First, though he draws a line between the mythological and the historical age, he still holds that myths, as such, are worthy to be reported, and that in certain cases it is part of his duty to report them. Secondly, he follows the example of such writers as Hecataeus in describing the natural and social features of countries. He seeks to combine the part of the geographer or intelligent traveller with his proper part as historian. But when we turn from these minor traits to the larger aspects of his work, Herodotus stands forth as an artist whose conception and whose method were his own. His history has an epic unity. Various as are the subordinate parts, the action narrated is one, great and complete, and the unity is due to this that Herodotus refers all events of human history to the principle of divine mechanism. If Sophocles had told the story of Cædæus in the *Edipus Tyrannus* alone, and had not added to it the *Edipus at Colonus*, it would have been comparable to the story of Xerxes as told by Herodotus. Great as an artist, great too in the largeness of his historical conception, Herodotus fails chiefly by lack of insight into political cause and effect, and by a general silence in regard to the history of political institutions. Both his strength and his weakness are seen most clearly when he is contrasted with that other historian who was strictly his contemporary, and who yet seems divided from him by centuries.

Thucydides was only thirteen years younger than Herodotus, but the intellectual space between the men differs so great that they seem to belong to different ages. Herodotus is the first artist in historical writing; Thucydides is the first thinker. Herodotus intertwines two threads of causation—human agency, represented by the good or bad qualities of men, and divine agency, represented by the vigilance of the gods on behalf of justice. Thucydides concentrates his attention on the human agency (without, however, denying the other), and strives to trace its exact course. The subject of Thucydides is the Peloponnesian War. In resolving to write its history, he was moved, he says, by these considerations. It was probably the greatest movement which had ever affected Hellas collectively. It was possible for him as a contemporary to record it with approximate accuracy. And this record was likely to have a general value, over and above its particular interest as a record, seeing that the political future was likely to resemble the political past. This is what Thucydides means when he calls his work "a possession for ever." The speeches which he ascribes to the persons of the history are, as regards form, his own essays in rhetoric of the school to which Antiphon belongs. As regards matter, they are always so far dramatic that the thoughts and sentiments are such as he conceived possible for the supposed speaker. Thucydides abstains, as a rule, from moral comment; but he tells his story as no one could have told it who did not profoundly feel its tragic force, and his general claim to the merit of impartiality is not invalidated by the possible exceptions—difficult to estimate—in the cases of Cleon and Hyperbolsus.

Strong as is the contrast between Herodotus and Xanthippus, their works have yet a character which dis-

tanguish both alike from the historical work of Xenophon in the *Anabasis* and the *Hellenica*. Herodotus gives us a vivid drama with the unity of an epic. Thucydides takes a great chapter of contemporary history and traces the causes which are at work throughout it, so as to give the whole a scientific unity. Xenophon has not the grasp either of the dramatist or of the philosopher. His work does not possess the highest unity either of art or of science. The true distinction of Xenophon consists in his thorough combination of the practical with the literary character. He was an accomplished soldier, who had done and seen much. He was also a good writer, who could make a story both dense and lively. But the several parts of the story are not grouped around any central idea, such as a divine Nemesis is for Herodotus, or such as Thucydides finds in the nature of political man. The seven books of the *Hellenica* form a supplement to the history of Thucydides, beginning in 411 and going down to 362 B.C. The chief blot on the *Hellenica* is the author's partiality to Sparta, and in particular to Agesilaus. Some of the greatest achievements of Epaminondas and Pelopidas are passed over in silence. On the whole, Xenophon is perhaps seen at his best in his narrative of the *Retreat of the Ten Thousand*—a subject which exactly suits him. The *Cyropaedia* is a romance of little historical worth, but with many good passages. The *Recollections of Socrates*, on the other hand, derive their principal value from being uniformly matter-of-fact. In his minor pieces on various subjects, Xenophon appears as the earliest essayist. It may be noted that one of the essays erroneously ascribed to him—that *On the Athenian Policy*—is probably the oldest specimen in existence of literary Attic prose.

Oratory. The steps by which an Attic prose style was developed, and the principal forms which it assumed, can be traced most clearly in the Attic orators. Every Athenian citizen who aspired to take part in the affairs of the city, or even to be qualified for self-defence before a law court, required to have some degree of skill in public speaking, and an Athenian audience looked upon public debate, whether political or forensic, as a compulsory test of proficiency in a fine art. Hence the speaker, no less than the writer, was necessarily a student of finished expression, and oratory had a more direct influence on the general structure of literary prose than has ever perhaps been the case elsewhere. A systematic rhetoric took its rise in Sicily, where Corax of Syracuse (466 B.C.) devised his *Art of Words* to assist those who were pleading before the law-courts, and it was brought to Athens by his disciple Tisias. The teaching of the Sophists, again, directed attention, though in a superficial and imperfect way, to the elements of grammar and logic, and Gorgias of Leontini—whose declamation, however turgid, must have been striking—gave an impulse at Athens to the study of elaborate rhetorical brilliancy.

The Attic Orators. Antiphon represents the eclectist, and what has been called the grand style of Attic prose, its chief characteristics are a grave, dignified movement, a frequent emphasis on verbal contrasts, and a certain austere elevation. The interest of Andocides is mainly historical, but he has graphic power. Lysias, the representative of the "plain style," breaks through the rigid mannerism of the elder school, and uses the language of daily life with an ease and grace which, though the result of study, do not betray their art. He is, in his own way, the canon of an Attic style, and his speeches, written for others, exhibit also a high degree of dramatic skill. Isocrates, whose manner may be regarded as intermediate between that of Antiphon and that of Lysias, wrote for a reader rather than for hearers. The type of literary prose which he founded is distinguished by ample periods, by studied smoothness, and by the temperate use of rhetorical ornament. From the middle of the 4th century B.C. the

Isocratic style of prose became general in Greek literature. From the school of Rhodes, in which it became more florid, it passed to Cicero, and through him it has helped to shape the literary prose of the modern world. The speeches of Isæus in all cases are interesting,—apart from their bearing on Attic life,—because in them we see, as Dionysius says, "the seeds and the beginnings" of that technical mastery in rhetorical argument which Demosthenes carries to perfection. Isæus has also, in a degree, some of the qualities of Lysias. Demosthenes exceeds all other masters of Greek prose not only in power but in variety. His political speeches, his orations in public or private causes, show his consummate and versatile command over all the resources of the language. In him the development of Attic prose is completed, and the best elements in each of its earlier phases are united. The modern world can more easily appreciate Demosthenes as a great natural orator than as an elaborate artist. But, in order to apprehend his place in the history of Attic prose, we must remember that the ancients felt him to be both, and that he was even reproached by detractors with excessive study of effect. *Æschines* is the most theatrical of the Greek orators, he is vehement, and often brilliant, but seldom persuasive. Hyperides was, after Demosthenes, probably the most effective, he had much of the grace of Lysias, but also a wit, a fire, and a pathos which were his own. The one oration of Lycurgus which remains to us is a masterly and striking reminder of both Antiphon and of Isocrates. Demetrius was merely a bad imitator of Demosthenes. There seems more reason to regret that Demades is not represented by larger fragments. The decline of Attic oratory may be dated from Demetrius of Phalerum (318 B.C.), the pupil of Aristotle. Cicero names him as the first who impaired the vigour of the orator's eloquence, "fashioning his own sweetness to the weight and dignity of his predecessors."

The place of Plato in the history of Greek literature is thus unique as his place in the history of Greek thought. The plain literary genius shown in the dialogues is many-sided. It includes dramatic power, remarkable skill in parody, a subtle faculty of satire, and, generally, a command over the finest tones of language. In passages of continuous exposition, where the argument rises into the higher regions of discussion, Plato's prose takes a more decidedly poetical colouring—never fond of sentimental, however, but lofty and austere. In Plato's later works—such, for instance, as the *Lysis*, *Timæus*, *Cratylus*—we can perceive that his style did not remain unaffected by the smooth literary prose which contemporary writers had developed. Aristotle's influence on the form of Attic prose literature would probably have been considerable if his *Rhetoric* had been published while Attic oratory had still a vigorous life before it. But in this, as in other departments of mental effort, it was Aristotle's lot to set in order what the Greek intellect had done in that creative period which had now come to an end. His own chief contribution to the original achievements of the race was the most fitting one that could have been made by him in whose lifetime they were closed. He bequeathed an instrument by which analysis could be carried further, he founded a science of reasoning, and left those who followed him to apply it in all those provinces of knowledge which he had mapped out. Theophrastus, his pupil and his successor in the Lyceum, opens the new age of research and scientific classification with his extant works on botany, but is better known to modern readers by his lively *Characters*, the prototypes of such sketches in our own literature as those of Hall, Overbury, and Laible.

III The Literature of the Decline

The period of decadence in Greek literature begins with the extinction of free political life in the Greek cities. So

Character
of the
creative
age in
Greek
literature

long as the Greek commonwealths were independent and vigorous, Greek life rested on the identity of the man with the citizen. The city was the highest unit of social organization, the whole training and character of the man was viewed relatively to his membership of the city. The market-place, the assembly, the theatre, were places of frequent meeting, where the sense of citizenship was quickened, where common standards of opinion or feeling were formed. Poetry, music, sculpture, literature, art, in all their forms, were matters of public interest. Every citizen had some degree of acquaintance with them, and was in some measure capable of judging them. The poet and the musician, the historian and the sculptor, did not live a life of studious seclusion or engrossing professional work. They were, as a rule, in full sympathy with the practical interests of their time. Their art, whatever its form might be, was the concentrated and ennobled expression of their political existence. *Æschylus* breathed into tragedy the inspiration of one who had himself fought the great fight of national liberation. *Sophocles* was the colleague of *Pericles* in a high military command. *Thucydides* describes the operations of the Peloponnesian War with the practical knowledge of one who had been in charge of a fleet. *Isotus* and *Phidias* gave shape in stone, not to mere visions of the studio, but to the more glorious, because more real and vivid, perceptions which had been quickened in them by a living communion with the Athenian spirit, by a daily contemplation of Athenian greatness, in the theatre, where a tragic poet idealized the legends of the past, in the acropolis where every citizen had his vote on the policy of the state, or in that free and gaseous society, full of beauty, yet exempt from votative constraint, which belonged to the age of *Pericles*. The tribunal which judged these works of literature or art was such as was best fitted to preserve the favourable conditions under which they arose. Criticism was not in the hands of a literary clique or of a social caste. The influence of jealousy or malevolence, and the more fatal influence of affection, had little power to affect the verdict. The verdict was pronounced by the whole body of the citizens. The success or failure of a tragedy was decided, not by the minor circumstances that it gained the first or second prize, but by the collective opinion of the citizens assembled in the theatre of *Dionysus*. A work of architecture or sculpture was approved or condemned, not by the sentence of a few whom the multitude blindly followed, but by the general judgment of some twenty thousand persons, each of whom was in some degree qualified by education and by habit to form an independent estimate. The artist worked for all his fellow-citizens, and knew that he would be judged by all. The soul of his work was the fresh and living inspiration of nature, it was the ennobled expression of his own life, and the public opinion before which it came was free, intelligent, and sincere.

Philip of Macedon did not take away the municipal independence of the Greek cities, but he dealt a death-blow to the old political life. The Athenian poet, historian, artist, might still do good work, but he could never again have that which used to be the very mainspring of all such activity,—the daily experience and consciousness of participation in the affairs of an independent state. He could no longer breathe the invigorating air of constitutional freedom, or of the social intercourse to which that freedom lent dignity as well as grace. Then came Alexander's conquests, Greek civilization was diffused over Asia and the East by means of Greek colonies in which Asiatic and Greek elements were mingled. The life of such settlements, under the monarchies into which Alexander's empire broke up, could not be animated by the spirit of the Greek commonwealths in the old days of political freedom. But the ex-

ternals of Greek life were there,—the temples, the statues, the theatres, the porticoes. Ceremonies and festivals were conducted in the Greek manner. In private life Greek usages prevailed. Greek was the language most used, Greek books were in demand. The mixture of races would always in some measure distinguish even the outward life of such a community from that of a pure Greek state, and the facility with which Greek civilization was adopted would vary in different places. Syria, for example, was rapidly and completely Hellenized. Judæa remained the process to the last. In Egypt a Greek aristocracy of office, both, and intellect existed side by side with a distinct native life. But, viewed in its broadest aspect, this new civilization may be called Hellenism. As *Hellenism* means "to do like a Hellenic," Hellenism means the adoption of Hellenic ways, and it is properly applied to a civilization, generally Hellenic in external things, pervading people not necessarily or exclusively Hellenic by race. What the Hellenic literature was to Hellas, that the Hellenistic literature was to Hellenism. The literature of Hellenism has the Hellenic form without the Hellenic soul. The literature of Hellas was creative, the literature of Hellenism is derivative.

1 Alexandria was the centre of Greek intellectual life. The *Alexandrian Museum* or *Library*, its "Museum" or *Library*, and its library, both founded by the first Ptolemy (Soter), gave to such attractions for learned men as no other city could rival. The labours of research or arrangement are those which characterize the Alexandrian period. Even in its poetry spontaneous motive was replaced by erudite Poetry, as in the hymns, epigrams, and elegies of Callimachus, in the enigmatic verses of *Lygion*, in the highly finished epic of *Apollonius Rhodius*, and in the varied prose, astronomical or medical, of *Aratus* and *Nicander*. The pastoral poetry of the age—*Doan* by origin—was the most pleasing, for this, if it is to please at all, must have its spring in the contemplation of nature. *Theocritus* is not exempt from the artificialism of the Hellenistic literature, but his true sense of natural beauty entitles him to a place in the first rank of pastoral poets. *Bion* of *Ionia* and *Moschus* of *Syracuse* also claim by the music and often by the pathos of their bucolic verse. But it is not for its poetry of any kind that this period of Greek literature is memorable. Its true work was in erudition and science. *Eudoxus* and *Aristarchus* (156 B.C.), the greatest in a long line of Alexandrian critics, set the example of a more thorough method in revising and interpreting the ancient texts, and may in this sense be said to have become the founder of scientific scholarship. The critical studies of Alexandria, carried on by the followers of *Aristarchus*, gradually formed the basis for a science of grammar. Translation was another province of work which employed the learned of Alexandria,—where the Septuagint version of the Old Testament was begun, probably about 300–250 B.C. Chronology was treated scientifically by *Eusebius*, and was combined with history by *Manetho* in his chronicles of Egypt, and by *Berosus* in his chronicles of Chaldaea. *Eudoxus* was at Alexandria in the reign of Ptolemy Soter. The general results of the Alexandrian period might perhaps be stated thus. Alexandria produced a few eminent men of science, some learned poets (in a few cases, of great literary merit), and many able scholars. The preservation of the best Greek literature was due chiefly to the unremitting care of the Alexandrian cities, whose appreciation of it partly compensated for the decay of the old Greek perceptions in literature and art, and who did their utmost to hand it down in a form as free as possible from the errors of copyists. On the whole, the patronage of letters by the Ptolemies had probably as large a measure of success as was possible under the existing conditions, and it was afforded at a time when there was special danger that a true literary tradition might die out of the world.

the transition to Hellenism

The
Greco
Roman
period

2 The Greco-Roman period in the literature of Hellenism may be dated from the Roman subjugation of Greece ("Greece made a captive of the rough conqueror," but it did not follow from this intellectual conquest that Athens became once more the intellectual centre of the world. Under the empire, indeed, the university of Athens long enjoyed a prominent reputation. But Rome gradually became the point to which the greatest works in every kind were drawn. Greek literature had already made a home there before the close of the 2d century B.C. Sulla brought a Greek library from Athens to Rome. Such men as Cicero and Atticus were indefatigable collectors and readers of Greek books. The power of speaking and writing the Greek language became an indispensable accomplishment for highly educated Romans. The library planned by Julius Cæsar and founded by Augustus had two principal departments, one for Latin, the other for Greek works. Tiberius, Vespasian, Domitian, and Trajan contributed to enlarge the collection. Rome became more and more the rival of Alexandria, not only as possessing great libraries, but also as a seat of learning at which Greek men of letters found appreciation and encouragement. Greek poetry, especially in its higher forms, rhetoric and literary criticism, history and philosophy, were all cultivated by Greek writers at Rome.

First part
146-46
B.C.

The first part of the Greco-Roman period may be defined as extending from 146 B.C. to the close of the Roman Republic. At its commencement stands the name of one who had more real affinity than any of his contemporaries with the great writers of old Athens, and who, at the same time, saw most clearly how the empire of the world was passing to Rome. The subject of Polybius was the history of Roman conquest from 264 to 146 B.C. His style, plain and straightforward, is free from the flow of rhetoric of the time. But the distinction of Polybius is that he is the last Greek writer who in some measure retains the spirit of the old citizen-life. He chose his subject, not because it gave scope to learning or literary skill, but with a motive akin to that which prompted the history of Thucydides—namely, because, as a Greek citizen, he felt intensely the political importance of those wars which had given Rome the mastery of the world. The chief historical work which the following century produced—the *Universal History* of Diodorus Siculus—resembled that of Polybius in recognizing Rome as the political centre of the earth, as the point on which all earlier series of events converged. In all else Diodorus represents the new age in which the Greek historian had no longer the practical knowledge and insight of a traveller, a soldier, or a statesman, but only the diligence, and usually the dullness, of a laborious compiler.

Second
part
46 B.C.
-629
A.D.

The Greek literature of the Roman empire, from Augustus to Justinian, was enormously prolific. The area over which the Greek language was diffused—either as a medium of intercourse or as an established branch of the higher education—was so extensive with the empire itself. An immense store of materials had now been accumulated, on which critics, commentators, compilers, imitators, were employed with incessant industry. In very many of its forms, the work of composition or adaptation had been reduced to a mechanical knack. If there is any one characteristic which broadly distinguishes the Greek literature of these five centuries, it is the absence of originality either in form or in matter. Lucian is, in his way, a rare exception, and his great popularity—he is the only Greek writer of this period, except Plutarch, who has been widely popular—illustrates the flatness of the aid level above which he stands out. The sustained abundance of literary production under the empire was partly due to the fact that there was no open political career. Never, probably, was literature so important as a resource for educated men, and the habit of

lecturing before friendly or obsequious audiences swelled the number of writers whose taste had been cultivated to a point just short of perceiving that they ought not to write.

In the manifold prose work of this period, four principal departments may be distinguished. (1) *History*, with monuments of *biography*, and *geography*. It would exceed the limits of the present summary to notice in detail the works which belong to this and to the other provinces, but it may be useful, for purposes of reference and classification, to give some chief names in each. History is represented by Dionysius of Halicarnassus—also memorable for his enthusiasm on the occasion and his effort to revive a fine standard of Attic prose,—by Josephus, Arrian, Appian, and Herodian. In biography, the foremost names are Plutarch, Diogenes Laërtius, and Philostratus; in geography, Strabo and Pausanias. (2) *Erudition and Science*. The learned labours of the Alexandrian schools were continued in all their various fields. Under this head may be mentioned such works as the lexicon of Julius Pollux, the commentaries of Galen on Plato and on Hippocrates, the learned miscellanies of Athenæus, *Ælian*, and Stobæus, and the *Stagireus* of Polyemus. (3) *Rhetoric and Oratory*. The most popular writers on the theory of rhetoric were Hermogenes, Aphthonius, and Cassius Longinus—the last the reputed author of the essay *On Sublimity*. Among the most renowned teachers of rhetoric were distinguished by "Sophists," or rhetoricians—were Dion Chrysostom, *Ælius Aristides*, Theonistus, Himerius, Libanius, and Hecodorus. *Ælius* Albin to the rhetorical exercises were various forms of ornamental or imaginative prose—dialogues, letters, essays, or novels. Lucian, in his dialogues, exhibits more of the classical style and of the classical spirit than any writer of the later age, he has also a remarkable affinity with the tone of modern satire, as in Swift or Voltaire. His Attic prose, though necessarily artificial, was at least the best that had been written for four centuries. The emperor Julian was the author both of orations and of critical pieces. The chief of the Greek novelists are Xenophon of Ephesus and Longus, representing a purely Greek type of romance, and Heliodorus,—with his imitator Achilles Tatius and Chariton,—representing a school influenced by Oriental fiction. There were also many Christian romances in Greek, usually of a religious tendency. Alciphron's satirical *Letters*—founded largely on the New Comedy of Athens—represent the same kind of industry which produced the letters of Phalaris and many similar collections. (4) *Philosophy* is represented chiefly by Epictetus and Marcus Aurelius, in both of whom the Stoic element is the prevailing one, by the Neoplatonists, such as Plotinus, Porphyry, Iamblichus, and by Proclus, of that eclectic school which arose at Athens in the 5th century A.D. The Greek poetry of this period presents no work of high merit. Babrius versified the *Æscop Fables*, Oppian wrote didactic poems on fishing and hunting, Nonnus and Quintus Smyrnaeus made elaborate essays in epic verse, and the Orphic lore inspired some poems and hymns of a mystic character. The so-called *Sybillic Oracles*, in hexameter verse, range in date from about 170 B.C. to 700 A.D., and are partly the expression of the Jewish longings for the restoration of Israel, partly predictions of the triumph of Christianity. By far the most pleasing compositions in the An are short poems which have come to us from this age as some of the short poems in the Greek Anthology, which includes some pieces as early as the beginning of the 6th century B.C., and some as late as the 6th century of the Christian era. The 4th century may be said to mark the beginning of the last stage in the decay of literary Hellenism. From that point the decline was rapid and nearly continuous. The attitude of the church towards it was no longer that which had

been held by Clement of Alexandria, by Justin Martyr, or by Origen.

There was now a Christian Greek literature, and a Christian Greek eloquence of extraordinary power. The latter became more and more estranged from the Greek literature—however intrinsically pure and noble—of the pagan past. At the same time the Greek language—which had maintained its purity in Italian seats—was becoming corrupted in the new Greek Rome of the East. In 529 A.D. Justinian put forth an edict by which the schools of heathen philosophy were formally closed. The act had at least a symbolical meaning. It is necessary to guard against the supposition that such assumed landmarks in political or literary history always mark a definite transition from one order of things to another. But it is practically convenient, or necessary, to use such landmarks. And, in this case, if a line is to be drawn at any one point between the Old and the Byzantine literature, it may be said that the edict of Justinian was the official record of the fact that the old literature of Greece was dead. Then came the Byzantine age, with its massive but formless erudition, its commentaries, annals, and lexicons, represented by such works as those of Eustathius, Photius, and Suidas. The golden time of the Byzantine literature was from about 650 to 1200 A.D. Just as this was drawing to an end, a poetry—at first satirical—arose in the popular dialect which had now decidedly diverged from the literary, and thus the link was made which connects the Byzantine period with the Greek literature of to-day. The Greek language has never died, and the continuity of Greek literature has never been broken.

See *History of the Literature of Ancient Greece*, by K. O. Miller, continued by J. W. Donaldson, *Critical History of the Language and Literature of Ancient Greece*, by William Mitton, *History of the Literature of Greece*, by Emile Burnet (1869), *Griechische Literaturgeschichte*, by Theodor Bergk (1873), *Grundriss der griechischen Literatur*, by G. Benliad (1873-1876), *Griechische Literaturgeschichte*, by R. Nisard (1876-1878), *Primer of Greek Literature*, in Macmillan's Series, by R. O. Jobb. (R. O. J.)

SECTION II.—THE BYZANTINE LITERATURE.

The literature of the Byzantine period, from the death of Justinian to the capture of Constantinople by the Turks, is singularly destitute of interest for the general reader. There is not a single work of intense human passion. Not one man appeared gifted with anything like genius. The most notable books are books of history written by those who were themselves actors in the scenes, or at the least were contemporaries or nearly contemporaries of the events recorded. There is always a sense of reality about such works, however they may have a general conception of the times may be. Of these historians a full account is given in the article BYZANTINE HISTORIANS. Some of these writers discussed other subjects. Remarkable amongst these is Constantine VII., Porphyrogenitus, who wrote or caused to be written a whole series of books, treating of the administration of the empire, the ceremonies of the court, war, and jurisprudence. He got up a cyclopædia of history and politics, of agricultural sciences, of the veterinary art, and of medicine, and ordered the preparation of an epitome of Aristotle's work on animals, of a collection of Greek epigrams, and a collection of the histories of saints. Constantine's works do not give so much an insight into what he could do as into what he wished to do. Some of the historians were really men of wide culture. Nicephorus Gregoras (born 1295) received a liberal education in rhetoric, astronomy, and other subjects, and his literary activity ranged over the entire field of human knowledge. Others again combined the study of rhetoric or philosophy with that of history. Pachymeres, for instance, wrote declamations of a pedantic and frigid nature on historical subjects, blending imagination with what he gathered from history.

The character of the Byzantine period is seen in the kind Poetry of poetry that it produced. There were some good epigram writers in the reign of Justinian, but after his time the anthology received very few additions. The first versifier

of importance that we meet in the progress of time is Georgius of Pisidia, who was deacon of the church of St Sophia in the reign of the emperor Heraclius (610-641). His muse celebrates various wars in iambic verse, such as was the against the Persians, the Avanic war, and the exploits of Heraclius. He also wrote several Christian pieces. Leo VI., called the Wise, who was emperor from 886 to 912, versified astronomical and ecclesiastical subjects, and wrote some prose works besides, most of which, if not all, deserve to be in oblivion. Theodorus, deacon in the church of St Sophia towards the end of the 10th century, used the iambic trimeter to narrate the capture of Crete, a work which derives all its value from the historical matter contained in it. Theodorus Prodromus is perhaps of all the Byzantine writers the one that comes nearest to the rank of a poet, yet even this approach is made only in some of his poems in the popular dialect, which have a strong satirical turn and a vein of humour. His more ambitious efforts have no claim to the title of poetry. The subjects are of wide range and various form—epistles, epigrammatical addresses, historical and didactic poems. Some of them are in a dramatic form, such as the *Catemysomachia*, recently edited by Haseha in his *Triclinia Biblicae*, in which besides the ordinary characters Prodromus introduces a chorus and semi-chorus, and the *κῆρυξ* and *ἀγγελος* so common in ancient plays. His largest poem is a romance called *τὰ κατὰ Περδίκην καὶ Δουρικλή*, consisting of nine books in iambic trimeter. It is entirely destitute of originality, and overlaid with rhetorical and unpoetic passages. It is given by Hercher in his *Σοφοῖς καὶ ἑρῶτες*. Prodromus flourished in the reign of Manuel I., Comnenus (1143-1180). Another Byzantine, Nicetas Engenianus, apparently of the same age, wrote a didactic poem, *τὰ κατὰ Δουρικλή καὶ Χαριτίαν*, which bears traces on every page of a close connexion with the similar work of Prodromus. Constantine Manasses also lived during the reign of Manuel I., Comnenus, and wrote a fiction in the vein of Politian, characterized by absurdity and poverty of thought and expression. Both of these romances are given in Hercher's *Σοφοῖς καὶ ἑρῶτες*. Veiss was during this period used for the most prosaic purposes. Michael Psellus the younger, about 1018 A.D., employed it to give a synopsis of laws, to treatise to give an exposition of history. The work of Veiss is now called *Χησάδες*, from its being divided into books of a thousand lines. It is written in the vernacular, and is a very heterogeneous mixture of fact and fiction, but occasionally contains references to customs and incidents which are not handed down to us elsewhere. Another critic, Joannes Pechasimus, wrote iambic verses, *ἐπὶ γυναικὶ κακῇ καὶ ἀγαθῇ καὶ ἡ πόλις*. Such were the subjects which the Byzantine muse treated, and as we have given a rather full catalogue of the poetical works produced in the Byzantine period in the ancient language, nothing remains to be said of the sterile nature of the poets and their poetry.

Dramatic poetry was also neglected, but enough was produced to keep up the continuity in the tradition of the drama. Sathas has tried to show that dramas were acted up to the latest period of the Byzantine empire, and though the notices are not numerous nor very conclusive, he seems to us to have proved his point (K. N. *Σάθα ἱστορικὸν δοκίμιον ἐπὶ τοῦ θεατροῦ καὶ τῆς Μουσικῆς τῶν Βυζαντινῶν*, Venice, 1878). We have already seen that Prodromus composed dramas. The most voluminous writer in this department is Manuel Philotes of Ephesus, who flourished from about 1280 to 1350, and who himself probably acted on

the stage. His dramas are occupied with the exhibition of the great deeds of his patrons, or resemble in some respects on Mæcenas, making characters of the various virtues.

Byzans The Byzantine period produced a considerable number of hymn writers. Among them may be mentioned Geanmanus, who was patriarch of Constantinople in the reign of Leo the Isaurian, Theodosius Studites, a theologian of some mark (759-826), the emperors Constantine Porphyrogenitus and Leo the king, and Photius, patriarch of Constantinople. The hymn writers who stand highest are Cosmas, who flourished in the 8th century, and whom W. Christ calls "princeps melodorum Græcorum"; Joannes Damascenus, a contemporary of Cosmas, and Theophanes d' Ipatris, who lived nearly a hundred years after Cosmas (see *Anthologia Græca* *Carminum Christianorum ante novum in W. Christ et M. Parnassus, Leipzig, 1871*).

Anthology The Byzantines occupied themselves with collections of poems, but the works of Cephalas and Planudes *Magnum* of this nature have already been discussed in the article *ANTHOLOGY*.

Prose writings When we pass from poetry to prose we meet with the same want of creative power. The Byzantines collect the writings of others and annotate, but they give us no original works. They performed two services to literature. They handed down the forms of literary expression, and by their indefatigable energy in excerpting and embodying in their own works the works of others, they have preserved for us many valuable documents of antiquity, or at least portions of them. During the Byzantine period there were also various phases of literary life. After the death of Justinian literary activity became gradually less, until in the time of the Iconoclasts intellectual culture was repressed, manuscripts were destroyed, and literature fell into disrepute and neglect. A revival took place under the Macedonian dynasty, but when the Latin empire was established in Constantinople, a relapse into semi barbarism again took place. Under the Palæologi the literary spirit once more came to life. Amidst these changes it was impossible for a vigorous creative literature to flourish, and the bright periods are mainly characterized by efforts to destroy the effects of the previous dark era by gathering together all kinds of information. Hence arose the compilations of Porphyrogenitus that have been already mentioned, and similar attempts were made at similar periods.

Several of the Byzantines attained to high eminence in the cultivation of science, but sometimes their exertions took a fruitless direction, especially when they aimed at discovering the method of converting the base metals into gold. It is in the study of grammar, in the production of lexicons and the annotation of the classical writers, that their best men have gained for themselves a name. The works of the writers on these subjects are of no interest to the common reader, but they furnish the scholar with many attractive problems. Who were the authors from whom the Byzantines borrowed? How far are their works interpolated? How far are the original authorities mutilated? These and such like inquiries crop up in connexion with almost every one of these writings. The writers who are best known as contributing to our knowledge of the ancients are Zetzels, Eustathius, Moschopolus, Thomas Magister, Joannes Pedasemus, and Demetrius Triclinus. Zetzels (probably the same word as Cæcus) lived in Constantinople about the year 1180. His *Chrestode* have been already mentioned. He wrote notes on Homer, Hesiod, and Æschylus, but he was especially opinion on Aristophanes.

Common sense Eustathius is well known to scholars for an elaborate commentary on Homer. He was brought up in Constantinople, and in 1160 became archbishop of Thessalonica and in 1174 archbishop of Myra in Lycia. Besides his labours

on Homer he wrote many theological and several historical works. Manuel Moschopolus belonged to the 13th century. He wrote many works on different points of grammar, and scholia on Pindar, the Tragedians, and Theophrastus. Thomas Magister of Thessalonica flourished in the reign of Andronicus II (1283-1332), and composed articles on ancient literary history, and scholia on Æschylus and other Greek writers. Joannes Pedasemus, who lived towards the end of the 14th century, is best known by his scholia on Hesiod, and Triclinus, who taught grammar in Constantinople at the same period, wrote scholia on Hesiod, Pindar, and the Tragedians. Nothing can exceed the stupidity of these writers and their fellow scholars of the Byzantine era. They misunderstood the acute remarks of their Alexandrian predecessors or bury them in verbiage. They are utterly inert in their discussion of historical questions, they are continually going wrong in their grammatical explications, and they are passionately fond of nonsense. Perhaps nowhere, to take one instance, in the whole of literature could wilder etymologies be found in greater numbers than in the scholia on the *Plutus* of Aristophanes. Yet these men thought highly of their work, and Triclinus tells us, in regard to a trivial book which he wrote on metrics, that he accomplished the task only through divine inspiration. Notwithstanding this, they have preserved for us within the quantities of rubbish many valuable facts and expositions derived from earlier ages.

Lexicon Ignatius Asson in the reign of Michael II (820-839), or Michael Gregorius, archbishop of Corinth in the second half of the 12th century, Holobolus, in the reign of Michael VIII, and Joannes Glycas, patriarch of Constantinople in 1316, are the principal writers on grammar. Of these Gregorius is best known, for his work on the Greek dialects, though full of mistakes, has deservedly attracted the attention of scholars. Of the writers of lexicons Suidas is the best known. He flourished in the 10th century. His work contains not only explanations of words but biographies of men. It is an undigested mass of statements which are often contradictory, but is of great value, for he has incorporated facts and expositions from early writers possessing of accurate knowledge. A full account of Suidas, and a discussion of all the questions connected with him, are given by Bonhardy in the prolegomena to his edition of the *Lexicon*. The *Etymologicum Magnum* is another important work of the Byzantine period, having been compiled in the 11th century. The appellation *magnum* or *μύα* does not belong to it originally, but was added by Minsurs, its first editor, or Callægus, its first printer. Gaisford in his edition has discussed this and other matters concerning the *Etymologicum*. A much smaller work by Philemon is a *Technological Dictionary*, written in the second half of the 12th century. Among the lexicon-writers is Photius, who was patriarch of Constantinople, and died in an Armenian convent about the year 891. Photius was a man of marked individuality, and his history is mixed up with that of his country. A more detailed account of him will therefore be found in a separate article. Porson prepared an edition of the *Lexicon*, which was published after his death by Dobree. The Leipsic edition contains a review by Blomfield (*Edin. Rev.*, xli, 1813) of Hermann's edition of Photius, in which the English reader will find a full discussion of the sources and value of the *Lexicon*. Photius also prepared a work generally called *Photus Bibliotheca*, containing extracts and notices of 280 books which he read while acting as ambassador in Syria. The nature of this work awaits more minute investigation than it has yet received, but there can scarcely be a doubt that some of the articles are the productions of a dishonest man, or of a late interpolator, or of both. His *Letters*, recently edited by Valartus, are of great importance for a knowledge of the times.

Music
and
metre

Several scholars of the Byzantine period wrote on the music and metres of the ancients. Their works abound in errors, but they preserve fragments of earlier works which are interesting and valuable. The work of Psellus the younger, called *Σύνοψις ἐς τὰς τέχνας μαθηματικὰς ἐπιστήμης*, contains large fragments of Aristoxenus (West phil., *Fragmente der Rhythmiker*, supplement to the first volume of his *Metrik*), and Marnel Hyennius (about the year 1380) wrote three books on harmonics, which contain among other things an exposition of the later Byzantine musical system (see Westphal, *Metrik*, vol. i: p. 319).

Rhetoric

Of the rhetoricians only a very few deserve mention. Joannes Doxopateus, who flourished in the reign of Alexius I., Comnenus (1081-1118), wrote several works of a rhetorical nature, which also to be found in Walz's *Rhetores Græci*. All that can be said of them is that they prove that he was a man of culture and refinement, and did not deserve the neglect and poverty which fell to his lot. A cluster of rhetoricians appeared in the reigns of Michael VIII. and Andronicus II., of whom the principal were Georgius of Cyprus, Nicephorus Chummus, and Theodorus of Hyrtæce. The emperor Manuel II., Palæologus, wrote several works of the nature of essays, and a large number of letters, several of which were addressed to Demetrius Cyrtones of Thessalonica, the author of a treatise on the *Contempt of Death* which has attracted some attention.

Philosophy

The study of philosophy was, generally speaking, neglected, but there were some who acquired renown as philosophers. Foremost amongst these was Michael Psellus the younger. He was born about the year 1018, and died shortly after the year 1105, after a chequered career. He was called by the men of his own age "Chief of Philosophers." His works range over the entire field of human learning. He wrote on the sciences, mathematical, physical, medical, on grammar and metres and music, on the doctrines of Plato and Aristotle, on psychology and dialectic, and very recently Sathas has edited a work of his called *A Century of Byzantine History*, which entitles him to a place among historians, a series of his letters which throw much light on the life of the Byzantines, and various discourses, panegyric and funeral. He lost the favour of the court and was supplanted by Joannes Italus, who also succeeded to the title of "Chief of Philosophers." Several of his scholars attained distinction as authors, or rather compilers, of commentaries on the Greek philosophers.

Theology

The theologians were to a large extent philosophers. The most famous among them was John of Damascus, who lived in the reign of Leo the Isaurian (718-741). He wrote on a great variety of subjects, theological and philosophical. The work by which he is best known is his *Sacra Parallela*, in which he has collected numerous passages from the writings of the fathers on such topics as repentance, faith, &c. The work is valuable as containing fragments of works which are now not extant. Along with Damascus the last of the Greek theologians. In subsequent times few appear worthy of attention, and it may suffice here to mention Nicephorus Callistus, "the Ecclesiastical Thucydides," who lived in the 14th century. He compiled an *Ecclesiastical History* from Eusebius, Socrates, Sozomenus, and the other earlier ecclesiastical historians, endeavouring at the same time to make his style more elegant than that of his predecessors.

Poetry

We find almost no attempt at light literature in prose during the Byzantine period. Only one work has come down to us of this nature, *The Loves of Hyeme and Hyemena*, by Eustathius the Mezeriotide. Hilberg, the last editor of the work, has tried to show with some success that Eustathius lived some time between 853 and 988. The work is full of imitations, and displays no inventive power.

A very full account is given of most of the writers here mentioned, with lists of their works edited and unedited, in the later volumes of the *Bibliotheca Græca* of Johannes Albertus Fabricius, edited by Hædæ, Hamburg, in 12 vols., 1780-1800; see also Curt., *Scriptores ecclesiastici* and *Historia Literaria*, &c. *Græciæ et Latinitatis Fall of the Roman Empire*, Müller, and Domänien's *History of Greek Literature*, 1838, Dr R. Nicola, *Græcisch-Literaturgeschichte*, vol. ii., 1876. Many of the works of the Byzantine writers are found only in *excerpts*, especially those of Yallovæ, Bevenwald, G. von Bekker, and Sathas, and often these editors investigate the history of the writers. Sathas has thrown much new light on the life of Psellus. (J. D.)

SLORION III.—MODERN GREEK LITERATURE

In narrating the history of modern Greek literature Psellus several difficulties of a peculiar nature present themselves, which do not emerge in an account of the literature of previous periods. The literature is no longer homogeneous, and we have to answer for ourselves the question whether we are to record the literary efforts made by Greeks on the literary efforts made in Greek. If we adopt the first course, we have to take notice of books written in Italian, French, German, and English, as well as in Greek, for the Greeks like the Jews were, during the three centuries of Turkish domination, a dispersed people. They found refuge far away from their native land, they spoke the languages of strange peoples, and when they published books, frequently used these languages. Few, however, forgot their native tongue, and there are consequently very few authors who, however copiously they may have written in the languages of the countries in which they settled, did not leave at least one work written in Greek. Ever since the kingdom of Greece has been established, many of her most distinguished men have written some of their best works in French, German, or English, in order to obtain a wider audience than they could expect if they had used modern Greek. We have to divide even those who used Greek into two classes,—those who used the ancient language and those who used the modern, though many have used both forms. The ancient language was still the literary language at the time of the capture of Constantinople, and the use of it as a vehicle of literature has been handed down in unbroken tradition to the present day. This has been especially the case with ecclesiastical writers. The church service is in ancient Greek. The New Testament is still read in the original language in Greek churches. The learned priests were familiar with the ancient language, and in learned treatises felt bound by a firmly impressed tradition to use only the language which the great fathers of the church had used. Cultivated Greeks in all lands still continued to make verses in imitation of the ancients. A change took place when Greece revived in the 19th century. All the great writers felt that it was pedantic to adopt many of the old forms of inflexion and construction,—that, in one word, the ancient language was not fitted to be the vehicle of modern civilization. They therefore resolved to adapt it, to omit what might fetter the full and free expression of modern thought, but to retain at the same time the body and substance of the language. And hence arose a form of the language which is practically identical with the ancient, but transfused with modern ideas, and fitted for the clear and rapid expression of modern literature. The influence of the ancient language on the modern is manifest in every part of it. And it could not be otherwise. Education is spread over every corner of free Greece. But in education the Greek child does not learn the grammar of the modern language but of the ancient. He often reads the last editor of the work, has tried to show with some success that Eustathius lived some time between 853 and 988. The work is full of imitations, and displays no inventive power.

of the Greek language acknowledge that alongside of the literary language there existed a conventional, which must have varied in different localities. We have the clearest traces of this language in the New Testament, as noticed under *GREEK LANGUAGE*, p. 135, and some ecclesiastical writers of a later date bear equally unmistakable indications of it. The *Pastor of Herma* is especially marked by such features, and the form of it given in the *Coder Sinaiticus* is as far advanced towards the modern as we find in several works of the 12th century written in the popular language. Very distinct approximations to the modern forms are also to be found in some of the apocryphal gospels, and in the *Testaments of the Twelve Patriarchs*, but especially in the *Apocryphal Acts and Apocalypses* published by Tischendorf. All these writings tend to show that it is impossible to fix on any period when the modern language may be said to be definitely formed. It grew out of the conversational language of earlier times. Till very recently some poems of Theodoros Prodromos (often called Prochoprodromus) was supposed to be the earliest distinct specimens of the modern language, but recent researches among the libraries have brought to light the fact that between the 10th and 15th centuries various works were produced in the modern form of the language. These researches are not yet concluded, and any results that are attained must be deemed merely provisional. The work which is now regarded as the earliest specimen of the new form is the *Σταυροί of Basilios Digenes*, written according to Legrand in the second half of the 10th century. The writer of this work unquestionably knew classical Greek well, and most of the lines would be perfectly intelligible to every scholar. But now and then words and constructions purely modern intervene. Yet there is a wide and marked difference between the language of this poem and that of the two poems of Prodromos, belonging to the 12th century, published by Corais, or the three more recently discovered by E. Miller, and published by him in his *Μεταφράσεις*, and subsequently by Legrand. In every line of these the difference comes upon forms which are quite strange.

The scholars will be best appreciated if we quote some lines from each of the writers. We take a passage from the *Digenes*, which contains more than the usual number of modern peculiarities.

Καὶ γὰρ ὁ μὲν δόλοισι καὶ ἐπιβόῃσι τοὺς
Μετὰ πᾶσι τοῖς ἀνθρώποις, ἄνθρωποι ἀβόλοι καὶ
Ὅραμα εἶναι, ἀβόλοι, ἐν ταύτῃ τῇ ἐσέφῃ
Ἰππῶν καὶ ἑφάρμοξεν ἐπὶ λαοῦσι τὴν πένητα,
Καὶ ἀπὲρ χρυσίου καὶ ἀργυρίου ἰδὼν
Ἄσπερον κατέβη χροῖα, καὶ ἐσέβη ἵν' ὁ κορυβαῖον,
Ὅτι καὶ κορυβαῖον ὁ γοῦν μετὰ τῆς ἀβόλῃς καὶ

Here the accent of *σκορῖος*, τοῖς for *ἀνθρώποις*, signifying white, τῇ for *ἐπὶ*, κορυβαῖον from *κορυμβόλον*, and *μας* for *ἡμῶν*, are the novel peculiarities, and none of them need puzzle the scholar. As a contrast we take a few lines from one of the poems of Prodromos published by Miller.

Ὁραμα τὰ χροῖα λαβὼν πὰρ τὸ γένος ἡ γάργαρος,
Μὲν καὶ χρυσίου τὸ φανὸν τὸ ἄλγος ἀφάρμοξεν,
Ἄλλὰ καὶ μετασέσωρον τὸ λένον ἐπὶ μέλῳ
Τ' ἐπιβόλον γραμματικὸν καὶ καλοεπιστολῆον
Καὶ πᾶσι γούρῳ γούρῳ καὶ τέρῳ καὶ βίῳ,
Κ' ἔβηεν τὸ π' ἡγοῦσα στυγλὴ καὶ γάργαρος

The lines are thus translated by Miller. — "Et moi aussi, j'ai essayé de la courtoisie, non pas pour me rassasier de pain de genre, mais de ce pain bis, dit de moyenne qualité, qui fait servir aux grammairiens et aux épistolaires de talent. Après maintes recherches, j'ai trouvé une même monnaie, et je l'ai donnée pour pur d'une alme de courtoisie." About the fall of Constantinople some of the learned Greeks took an interest in the popular form of the language, and one of them, Sophianos, composed a grammar in the first half of the 16th century, which Legrand has published,

along with a translation by the same scholar of Pitsarch's treatise *On the Education of the Young*, into modern Greek. This grammar proves that the popular form of Greek was by that time fully developed, and it might still be taken as a good exposition of the ordinary spoken language of illiterate Greeks. Of course there were great varieties in this popular form. Almost every small district and every island had inflections, constructions, and words peculiar to themselves. Kavalas wrote to Martin Crusius in the end of the 16th century that there were upwards of seventy modern dialects, of which that of the Athenians was the worst. But however many dialects there may have been, there is no reason to suppose that the difference was such as to prevent a Greek residing in one part of Greece from understanding a Greek residing in any other part. Since that time changes have taken place in the popular forms. Turkish words were introduced to a larger extent, but the language has remained substantially the same. There is also indeed still a considerable variety of forms in the different districts, and one of the most amusing of modern Greek comedies, *Ἡ Βαβυλωνία ἢ ἡ κατά τόντον διαφορά τῆς Ἑλληνικῆς γλώσσας*, by D. K. Byzantios, is based upon the different dialects spoken by the Greek of Asia Minor and the Peloponnesian, the Chian, Cretan, and Cypriot, the Albanian and Heptanesian. This language is no longer the language of cultivated Greek society, of literate, or of the sciences. When Greece was stirred into new life, no question arising about the patriotic Greek more intensely than that of the form which the language should take. Some, led by Olympos, maintained that the popular language was really ancient, that it was a mixture of *Æolic* and *Doric*, and that it ought therefore to be retained. Others, with Economos as their champion, were for adopting the classical language with a few slight modifications which could claim the sanction of some of the best Byzantine writers. A third party, headed by Corais, were for stoning a middle course, and they have ultimately triumphed. Colonel Leake has well described the present language "This style," he says, "may with tolerable accuracy be defined to consist in Hellenic words, arranged in the syntax of modern Europe, with a grammar partly Hellenic and partly modern. Interventions and transpositions occur with almost the same degree of frequency as in Italian, and the arrangement in general is not much more complex than that of our own language." (*Researches*, p. 54). We extract a specimen of it from the sixth volume of "Epilogos" of the *Library of Greece* by Paparrhagopoulos.

Ὅσα τῇ 1790 γὰρ τοῦ θένον ἀντιπροσώπων καθεύδοντες ἐπὶ τῇ μετὰ τὴν ἀποκρίσιν τῶν ἀπαιτῶν τοῦ καὶ παρακλήν τῆς ἑγέρσεως οὐκ ἐκινεῖται ἀπὸ τῶν ἀντιπροσώπων, ὁ ἑλπίς εἴτα τὴν ἐπὶ τῶν πᾶσι τῶν Ῥωμαίων ἢ καὶ ἡλικίᾳ Ῥωμαίων ἀλλὰ δὲ Ἑλλήνων καὶ ἀπὸ γυναικῶν τῶν Ἀθηναίων καὶ τῶν ἀκαδημαϊκῶν

In this sentence all the words are ancient. Two of them are connected, *καὶ* for *et* and *ἐπὶ* for *ad*, and some have had their meanings modified. The remarks of Paparrhagopoulos relate to a subject which demands a brief notice. The Greeks at the time of the capture of Constantinople were proud of being *Ῥωμαῖοι* or Romans, and the term included all the Christians who formed the subjects of the Greek empire. Hence the term *Roman* was the name given to the popular language. But during all the period of the Turkish domination the Greeks occasionally spoke of themselves as *Ῥωμαιοὶ* and *Ἕλληνες*, and when the period of revival came, they cast off the old name of *Ῥωμαῖοι* and *Ῥωμαϊκά*, and spoke only of *Ἕλληνες* and *Ἑλληνικά*. Accordingly the Greek language is now spoken of as the Hellenic tongue. When it is necessary to distinguish the modern from the ancient, the language of cultivated men is called *Neo-Hellenic*, *νεοῦ Ἑλληνικῆς*, and the popular form is styled *ἀπολλομένη* (see especially Dr. Cloyd's *Roman and Modern Greek*, Edin 1855).

Greeks
of the
Renaissance
before
the fall of
Constanti-
nople

In narrating the history of this literature, we have at the earliest stage to treat separately those who used the classical language and those who used the vulgar. In both cases we cannot draw a fast line at the date of the fall of Constantinople, for, though this event is of great importance in the history of the Greeks as a people, it does not constitute a break in the literary history. It is often imagined that the dispersion of the Greeks in 1153 stood in close connexion with the revival of literature in Western Europe. But the fact is that the Greeks had come into contact with the Western long before, and then influence had become decided before the Turks seized the capital of the Greek empire. The crusades had brought Greeks and Latins together. The Latin empire in Constantinople had made the contact still more frequent. Greeks and Latins had entered into keen discussion on the truth of the dogmas in regard to which they differed. Some of the Greeks had become converts to Roman Catholicism, or at least denied the union of the Eastern and Western Churches. In these circumstances they often left their native land to seek preferment in the church in which they could labour with greater sympathy. Many of them also had become connected by marriage or other ties with the Italian nobles who ruled in the *Aegean*, and circumstances led them to settle in Italy. Of the Greeks who thus found their way to the West before the taking of Constantinople, the most prominent were Leon or Leontios Pilatos, Georgios Gemistos Plethon, Manuel and John Chrysolaos, Theodoros Gaza, Georgios Trapezuntios, and Cardinal Bessarion. Hedy has given a full account of most of these men in his work *De Græcis illis tribus Linguis Græcæ Latine et lingue II. germanorum Instrum. a. toribus* (London, 1742). Pilatos was a native of Thessalonica and a pupil of Basilian, a Calabrian monk who taught Petrarch Greek. Pilatos himself taught Boccaccio his native language, and expounded Homer in Florence. He died in 1364. Gemistos was a native of Lacedæmon. He taught in Constantinople, Athens, and Florence, and had in all places a large number of pupils who eagerly imbibed his Platonic teachings. His works were numerous, but most of them still lie hid in the great libraries of Europe unpublished. Manuel Chrysolaos was one of the pupils of Gemistos, and is famous as the translator of Homer and Plato. Both he and his brother John had many illustrious men as their pupils in Greek. Manuel taught in Milan, Venice, Padua, and Rome. He has the merit of composing the first Greek grammar that appeared in the West (*εργασίαν*), published for the first time in Venice (1484). He made his first visit to Italy in 1393 in the capacity of ambassador from the Greek emperor to seek aid against the Turks, and he returned to Italy on the accomplishment of his mission that he might spread the knowledge of Greek literature. He was sent as deputy to the council of Constance, and he died in Italy in 1416. Theodoros Gaza, a native of Thessalonica, fled from his native place in 1430, and became a teacher of Greek in Ferrara, Rome, and Florence. He prepared a Greek grammar in four books (first published in Venice 1495), which continued for a long time to be a text-book in Greece and other countries. He translated many of the classical writers, and wrote on the ancient history of the Turks and on theological subjects. He died in 1478 in Calabria, where he had settled in his old age. Georgios Trapezuntios was born in Cete in 1396. He received the appellation of Trapezuntios because his family had come from Trebizond. A Venetian noble took him to Venice to teach Greek in 1426. He removed to Rome in 1440, where he remained till 1450, at first highly honored, but subsequently, through the bitterness of his temper, falling into disgrace. After that he led a wandering and miserable life, and died in 1486. He translated many of the Greek writers into Latin, and wrote a treatise in which he com-

pared Plato with Aristotle. Cardinal Bessarion was a native of Thessalonica. He received his education in Constantinople. In 1425 he went to the Peloponnesus to hear Gemistos expound the philosophy of Plato. In 1439 he removed to Italy, after he had been a while neighbor of Niema, because the Greeks bitterly resented his attachment to the party which saw no difficulty in a union between the Western and Eastern Churches. He rose to great honour in the West, obtaining the cardinal's hat. He died in Ravenna in 1472. He was passionately attached to the classical literature of his country, and took a profound interest in the education of his fellow countrymen. He aided in the most liberal manner all the men of ability who came from Greece. He made a large collection of manuscripts. He translated portions of Xenophon, Aristotle, Theophrastus, and other Greek writers, and he wrote on the theological questions of the day.

The Greeks who were most prominent in spreading the knowledge of Greek in Europe after the fall of Constantinople are Joannes Agriopoulas, Demetrios Chalcocondyles, after the fall of Constantinople, and Marcus Musurus. Agriopoulas was a native of Constantinople, and there taught Constantine Lascaris. In the West he taught at various times in Padua (1434), Florence (1456), and Rome (1471), and had amongst his scholars Angelus Politanus and Reuchlin. He translated many of the works of Aristotle. Chalcocondyles was a native of Athens and became a teacher of Greek in Florence in 1471, after some time he removed to Milan, where he died in 1511. He edited very many of the Greek authors. Constantine Lascaris, descended from a noble Bithynian family, taught Greek in various Italian cities, and finally settled in Sicily, where he died about 1500. He wrote a large number of works, most of them still unpublished. His best known work is his *Gramma*. He also transcribed manuscripts, and made a large collection of them. His name is well known to modern readers through the romance of Villamain (*Lascaris ou les Græcs du X^{ème} siècle*). John was probably the younger brother of Constantine. He was principally employed in collecting manuscripts for the great men of the day, wrote several works, and edited several Greek books for the first time. He died at Rome in 1535.

Almost all these men were rather employed about literature than engaged in producing it. They taught Greek, several of them wrote Greek grammars, they transcribed and edited Greek classical writers, and they collected manuscripts. Bessarion laid the foundation of the library of St Mark in Venice. The collections of Constantine Lascaris formed the nucleus of the Escurial library, John Lascaris and his pupil Budeus gathered the first stores for the national library in Paris, and Pope Nicholas V employed the services of Bessarion, Gaza, and Chrysolaos in establishing the Vatican library. But almost none of these men accomplished much in literature strictly so-called. The question which most deeply interested them was the philosophy of Plato and Aristotle. Somehow or other the championship of Plato was undertaken by those Greeks who eagerly desired the union of the Greek and Latin churches, and the philosophy of Aristotle was upheld by the opposite party. Gemistos, whom Mahomet II appointed as patriarch of Constantinople after the capture of the city, showed himself a keen partisan of the Platonists, and hurled his thunderbolts against the Aristotelians. Gemistos Plethon was the chief defender of the Platonic philosophy, and received unmeasured abuse from George of Tolosani for his heterodox opinions. The works on these subjects were numerous, but beyond these theological questions (for they were theological rather than philosophical) there is not much. Scholarship continued to survive in Greece or among the Greeks for a long time after the

Turks began to rule in Greece, and a considerable list might be added, including the names of Apostolos, whose collection of Greek Proverbs is well known to scholars, and his son Aisseus, metropolitan of Monemvasia. Among the few who still used the Greek language for literary purposes Leo Allatrus is prominent. His Greek verses show skill and cleverness. Mention also should be made of Constantine Rhododanakis, honorary physician to Charles II of England. He wrote verses on the return of Charles to England, not without merit (see a very curious life of O Rhododanakis published in Athens, 1872).

Early
works in
modern
Greek
Romantic
poems

We now return to the literature in the modern language, and here again we have to go back several centuries before the fall of Constantinople. We have already seen that the earliest production is the *Exploits of Digenes Akritas*, so called because he was the son of a Turk and a Greek, and because he spent a large portion of his time in watching the frontiers. There is reason to believe that his adventures formed the subject of poems in many parts of Greece. Some have called him a Cyprian Hercules, and believe him a kind of mythological character, while others regard him as a genuinely historical personage. The poem published by Legrand describing his adventures is imperfect. Many of the incidents are of a purely romantic nature. From the 13th to the 16th century many poems were composed in the popular language. Our knowledge of these works is still incomplete. Several of them lie hidden in the great libraries of Europe, but much is now doing to increase our knowledge. Many have been already published in the collections of Manophrydis, Sathas (*Anthologia*), Wagner (*Cammina Melis Beni*), and especially Legrand. They all breathe the spirit of chivalry, and are full of romantic adventures and tales of love. M. Gidel has the special merit of drawing attention to those poems in his *Études sur la Littérature Grecque Moderne* (Paris, 1886), and he has gone further, into the subject in his *Nouvelles Études sur la Littérature Grecque Moderne* (Paris, 1878). He has proved that the romances which delighted the knights of France and Italy found their way probably through the Genoese and Venetians and some French families into Greece, especially into the islands. The Greek minstrels took them and adapted them for their Greek audiences. He has given an analysis of the various poems and compared them with the Western forms. The most important in modern Greek are "The Old Knight" (12th century), a tale of the Round Table, "The Story of Belthandus and Chrysanteus" (probably 12th century), "The Loves of Lybistros and Rhodamnia" (probably 12th century), "The War of Troy," taken from the *Guerre de Troie* of Bonnet de Sainte-Maine, who wrote in the second half of the 15th century (the Greek translation was made some time before the fall of Constantinople), "Flots and Blanchefleur," and the "History of Imbeius and Marguions." There are various other poems belonging to this period of a different character, such as the "Oracles" of Leo the Wise, imitations of *Reneke Fuels*, and "Phryniogloss." The history of Alexander the Great was a favorite theme, and there is a Greek version of Apollonius of Tyre. We do not know the authors of any of these poems. But about the time of the fall of Constantinople we meet with the names of some versifiers. Pappaspondylis Zotos described the battle of Varna (1444) in verse, and from the poems we gather that he was present at it. We have three poems written by Georgios Lamentis (1450-1500), one "On the Death of the great Commander of the Romans, Belshazzar," another "On the Plague in Rhodes," which took place in 1498, and a third, "A Complaint on the Fall of Constantinople." Some have been inclined to think that this last cannot be the work of Georgios. From an examination of the poems of Georgios and some other phenomena, Conius, in the pro-

legomena to the second volume of the "Astron," came to the conclusion that rhyme was unknown to Greek poems before the fall of Constantinople, and had become established as a feature of them when Georgios wrote on the Rhodian plague. Gidel has accepted this as giving a clue to the dates of Greek poems. A third versifier was Jacobus Thivolis of Corfu, who lived in the beginning of the 16th century. He wrote the history of Tagipuspa, a Venetian noble, and the history of the king of Scotland and the queen of England, a tale taken from Boccaccio. Almost none of these poems have poetical merit, but they are interesting as specimens of the popular language, and curious as throwing light on the manners and thoughts of the Greeks of those days.

From the earliest times the Greeks were in the habit of putting into verse any remarkable occurrence that stirred their feelings. Crœsus tells us that in his time Greeks, especially on the islands, contended with each other in repeating or extemporizing verses, and the custom has remained down to the present day. Accordingly the Greek popular poetry is rich in historical subjects. We have already noticed the poems on the battle of Varna and on the taking of Constantinople. There is also a chronicle of the conquest of the Morea (given by Filissen in his *Analekten*). There are several lamentations over the fall of Constantinople. And the khapshe ballads, relate real adventures. Almost every leader in the war of independence had his song in his honour. Some have thought that the largest portion of the ballad poetry of the Greeks is recent, but Legrand's collection lately published shows that some of them belong to very early times, being edited from a manuscript of the 16th century. There are two or three famous historical poems connected with the islands. Especially noteworthy is one on the exploits of Moreusos Bona by Coconoe.

There are three poems belonging to the 16th and 17th centuries which have obtained wide popularity among the Greeks. The first is the *Érotokritos*, the epic poem of modern Greece, of about 11,400 lines. Of its author Vincenzo Cornaro, a Cretan, we know almost nothing, but it is probable that he belonged to a noble Venetian family and lived in the middle or towards the end of the 16th century. The tale is one of two lovers who, after many trials of their fidelity to each other, are at last united and blessed. There is genuine poetry in the work. Many of the scenes are charming, and, as M. Gidel remarks, there is not a single situation which shocks propriety nor a single sentiment which is not modest and of rare purity. The second poem is a drama called *Erophile*, and its theme is the love of Panaretos and Erophile. The author of it was Georgios Choratzis, who was brought up in Rheblymnos, a Cretan town, and lived towards the end of the 16th and beginning of the 17th century. It was thought to be nearly the only drama of this period, but Sathas has brought to light the fact that there was a considerable number of them, and he has already published three, *Zeno*, *Sathas*, and *Cyparis*, in addition to the *Erophile*. Some of them are translations, and all of them are closely connected with Italian dramas of the same period. The *Erophile* has interludes to each act, dealing with an entirely different theme, and most probably written by a different author. The third poem, *The Shepherdess*, is a charming idyll written by Nicolaos Demetriou, a native of Apocœone in Creta, who lived in the beginning of the 17th century.

There are few prose productions of any importance early belonging to the early period of modern Greek literature. Pappas mentions works written by Malaxos, Zagonoulas, and Canavaritis. Sathas has more recently brought to light a number of chronicles, such as those in the second volume of his *Bibliotheca Græca Medii Ævi*, that relate the history

of Cyprus, Leontios Machairas, in the beginning of the 15th century, and Georgios Boustronios, whose narrative extends from 1456 to 1501. His sixth volume contains curious documents (the assizes of Cyprus, Cretan wills, &c.), which afford insight into the forms of modern Greek prevalent among the Cypriotes and Cretans, though a considerable number of them are written in classical Greek. Miklosaich and Müller have made a similar collection of documents, *Acta et Diplomata Græca Medii Ævi*. Even in the 18th century we find the classical language used much more frequently than the modern. Meletios, the man whose name stands most prominent in this period, wrote his *Kalevateri Histo-ri-ya from the time of Christ to the year 1700* in ancient Greek, and his work had to be translated into modern Greek to give it currency among the masses. Another ecclesiastical history by Sergios Makrianos, given in the collection of Sathas (from 1750 to 1800), is written in the same language, and we find some writers like Chalkias Daponte and Meletios using sometimes the ancient and sometimes the modern form. We have almost no attempts at elegant literature in the modern Greek prose of this period. But it is possible that manuscripts containing such works may be hid among private family documents. One has recently been edited by Innocent Damaris (Tunin, 1872), *The Loves of Eregelos and Rasma*, by Holophilos, which was most probably written between the 12th and 16th centuries, but might have been written by any one of the Sathas Eriotes, as the language discloses modern forms only in one or two sentences.

Literature of the 18th century

In the 18th century a revival of enthusiasm for education and literature took place among the Greeks. Schools were established in every important Greek city, school books and translations from Continental languages poured forth from the presses of Venice, Trieste, Vienna, and other places where the Greeks had influence. The leaders in this movement were Engimios Bulgarias, Nikephoros Theotokis, and Adamantios Corais. The first two, both natives of Ochia, were devout adherents of the Greek Orthodox Church, warm patrons of Russia, and both became archbishops in the Russo-Greek Church. They were true but narrow patriots. They wrote much in defence of Greek orthodoxy as against Latin heresy. Bulgarias also wrote on philosophy and Theotokis on physics, and the latter prepared or translated educational treatises on physics, mathematics, and geography. Far before these stands Adamantios Corais, who was above everything a Greek of widest aim and of the greatest culture. He was born in Smyrna in April 1748. He studied nearly every branch of learning, medicine, theology, and literature, in the universities of Italy and France, and then devoted his life to the re-education of his country from ignorance and servitude. He edited a very great number of the classical writers, with admirable critical notes, and generally with prolegomena, which tried to awaken the interest of his countrymen in their past glories, and strove to induce them to emulate their ancestors. He also devoted his attention to the modern language, especially in his *Araxia*, discussed the writings which had appeared in it, prepared a prosaical dictionary of it, and determined the mode in which the popular dialect might become the basis of a literary language.

Modern literature

From the time of Corais we may date a new era in the history of the literature. Henceforth the works become exceedingly numerous, and efforts are made in every direction of literary activity. Perhaps no nation now produces so much literature in proportion to its numbers. The Greeks seem restless in their desire to give expression to their thoughts. They have indeed great difficulties to contend with in the way of publishing. The number of readers is necessarily small, owing to the smallness of the nation. To take an instance, one of their most important

periodicals, the *'Aðravn*, containing articles on archaeology and literary history, which should be known to all scholars, had not more than 150 subscribers in 1876, as we are informed in the preface, 600 copies were published, of which 100 were sent by the university of Athens to the various libraries in Europe and America, 150 were distributed free, and only 150 were subscribed and paid for. The number of subscribers had not increased in August 1879. In these circumstances many rich Greeks have come nobly forward and published books at their own expense, and much credit is due to the Zosimades, the Ralli, and the other Greeks who have saved their country in this way. Very frequently scholars produce their best works for periodicals or even newspapers, and some most valuable treatises have been published as supplements to Greek periodicals. Translations of many of the best French novels have also been given away with these periodicals, and occasionally some of our most esteemed English writers have been thus made known to the Greeks, for instance, a translation of the *Bride of Lammermoor* was published by the editors of the *Pandora*. These circumstances, while impeding the production of Greek books, also tend to prevent foreigners from knowing exactly what the Greeks have done. Another circumstance that marks this period deserves notice. Almost every literary man of eminence makes efforts in every literary direction. Theologians, scholars, physicians, are all found in the list of poets. The same persons write school-books, histories, dramas, lyrics, and novels. It would be impossible to give even a notion of this endless activity. All that can be done is to point out a few of the principal writers.

In the early part of this period two poets claim our notice, Poesly Rhegas of Velestino in Thessaly, and Christopoulos Rhegas was the poet of liberty, and his great war song, *Acðre paides twn Ellhñwn*, is well known to English readers through Byron's translation. He wrote many songs or hymns calculated to incite his fellow-countrymen, but acting rashly he was seized and shot at Belgrade in 1792 at the age of forty-four. Christopoulos was born in Macedonia in 1770, and died in 1847. He devoted himself to songs of love and wine, and many of his songs contain are melodious, graceful, and charming. Somewhat later than Christopoulos comes Jacobos Rizos Neroulos, who was born in Constantinople in 1778, and died in 1850. Neroulos wrote lyrics, tragedies, and comedies with considerable success, but his best known book is a work published at Geneva in French in 1826—*Cours de la littérature Grecque moderne*—and admirably translated into modern Greek by Miss Olympia Abbot of Thessalonica. It is an interesting account of modern Greek literature up to the time at which the lectures were delivered, and is written in a bright and forcible style. It is perhaps rather too favourable to the phanariots, to whom Neroulos himself belonged, but it is an honest defence, and it has to be remembered, on the other hand, that he lashed the vices of the phanariots with great boldness in his comedies. From these writers we pass to the era of the independence of Greece. During this last period three writers have appeared who have established for themselves a permanent place in the history of mankind as men of true genius, Panagiotis Sontes, Alexander Sontes, and Alexander Rizos Rangabé. Panagiotis and Alexander Sontes were brothers, and belonged to the phanariots. They were born in Constantinople in the first quarter of this century, and were educated first in Olous and then in the universities of Italy and France. They threw all their energies into the war for independence, and sang of its glories. But they conceived a determined dislike to Capodistrias. They were still more bitter against Otho, and adopting extreme opinions and always discontented, they fell out of sympathy with their fellow countrymen. Panagiotis received high poets of

honour at the end of the war of independence, and Alexander was oftened great literary distinctions, but the unmitigated abuse and contempt which they both, but especially Alexander, heaped on all men in authority rendered absence from their country a necessity. Alexander died in Smyrna in a hospital in 1863, and Panagiotis died at Athens in utter obscurity in 1868. Both tried various forms of poetry, but as nearly all critics have remarked, Panagiotis was always lyrical and Alexander continually returned to satire, whatever his subject might be. Both had a rich command of musical language, were highly ideal in their conceptions, were strongly patriotic, and possessed an ardent love of liberty.

Of the two the muse of Panagiotis strove more after the sublime, but was less steady, less uniformly excellent than that of Alexander. Both were deficient in giving unity to their poems, or in forming sustained and original plots. The plays of Panagiotis remind one of such works as Bailey's *Pædia*, whose there is a profusion of poetical conceptions but no coherent whole. Many passages in the works of both brothers bear a strong resemblance to lines which are to be found in the writings of poets whom they admired, especially Lamartine, Béranger, and Byron. The spirit of Byron pervades both. The principal works of Panagiotis are "*Odyssæus* (The Traveller), a drama in five acts, for which Byron's *Manfred* stood as model, *Meorias* ή *τὰ πρὸς ἱερὸν Περσέω* (The Messiah), also a drama in five acts, and three other plays *Pædæus*, *Cavassalus*, and *The Unknown*, in all of which there is a nice want of character and plot, and a rich store of poetry, a novel, *Λαυρέν*, and many lyrics, especially "*Ἡ Κρίσις*," first published in 1835. He died in his later days to strike out a new style in modern Greek, but his effort was unsuccessful. Alexander's principal works are—*Παράφρασις τῆς Ἑλλάδος*, a collection of poems for the most part bitterly satirical, recently republished by Logothetis at the end of his grammar, "*Ὁ Περικλέας* (The Wanderer), a poem which was suggested by and contains many direct imitations of Byron's *Childe Harold*, and several comedies, *The Prodigal*, *The Penitent*, *The Unnatural Poet*, and *The Constitutional School*, and numerous odes and lyrical pieces. He also wrote one comic tragic novel, *Ἐξέπνορος* (1831), or *The Banished One* of 1831.

Rungabé This other great poet that regenerated Greece has produced is Alexander Rios Rungabé. He was born in Constantinople early in the century, and belonged like the Sontozes to a phanariot family. He thus describes his own career—"A pupil of Vardalochos and Gennadios, he completed his studies at the military school and at the university of Munich. In his own country he was at first an artillery officer, then a councillor in the ministry of public instruction and also in that of the interior, professor of technology in the university (of Athens), minister for foreign affairs, deputy, and later on representative of his country in different foreign countries." His works are of wide range. He has written a grammar of modern Greek, contributed to a dictionary and a cyclopaedia, composed a history of ancient Greece, and edited many school books. He has written an able work on ancient art, and an exceedingly valuable and scholarly work on inscriptions, *Antiquités Helléniques*. He has contributed much to the *Pandora*, the *Archæological Journal*, and the *Revue*. He has narrated the results of his travels, and discussed mathematical problems. He has also composed several novels. And he has written a history of the literature of modern Greece,—bright, genial, sparkling, and full of true and sometimes tendentious criticism. It is in his poems, however, that he claims to remembrance will specially rest. In these he shows fine poetic feeling, a rare command of exquisite and harmonious language, and a singular beauty and purity of thought and sentiment. His poetical works consist of a

large collection of hymns, odes, and songs, 100 narrative poems, ballads, four tragedies and three comedies, a translation of the *Antigone* of Sophocles, and of three plays of Aeschylus.

Besides these three poets there is a great number of other writers who have composed poetry of considerable merit, so is but we can only mention the names of a few,—Valaoritis, Zalamastar, Solomos, Vlachos, Kokkinakis, Caisasotatos, Tantalides, Zampelios, Orphanides, Cleon and E. Hanganb, Euphrosyne Samatradis, and Antoniadis. Elias Tantalides, who for a long time was blind and who died a few years ago, published an interesting collection of songs, including many rhymes and school songs, with music (Athens, 1876). The production of poetry was much stimulated by an annual poetical contest. A sum of money was set aside for prizes, poems were sent in, judges were named, and when all was ready, a speech was delivered in the university by the convener of the judges, assigning their reasons for their decision and giving criticisms of the poems. The envelope of the successful candidate was then opened, and he received the laurel wreath with a thousand dinars. From what is stated in the *Athenæum* of Athens for May, June, July, and August 1878, where the exposition of the contest of 1877 is given, it would seem that probably that of 1877 was to be the last. Amongst the poets of recent days special mention should be made of Theodoros A. Parnassios, who while in Manchester did much to advance the works of his fellow-countrymen known to Englishmen, and the best works in recent English literature to Greece. Among other things he translated Rossetti's *Life of Lorenzo de' Medici*, Byron's *Sardanapalus*, Villenard's *Lazarus*, and poems of Goldsmith, Bryant, Burns, Goethe, and Victor Hugo. He also wrote original poems of great merit, and a novel called *Ethéria*. Two writers have distinguished themselves by poetic compositions in ancient Greek, Loukas and Philippus Joannes.

The drama is a form of poetry to which the Greeks feel drama peculiarly prone. Rungabé gives a list of ninety writers of dramas in his *History of Modern Greek Literature*, and the list he says is incomplete. Out of these writers we may select for notice Demetrios N. Benardakis, whose *Μαρία Δοξομαχί*, "Maria, the daughter of Duquenois," with its prolegomena, has deservedly attracted much attention and been analysed by Gidel.

In prose there is no department of literature which is not handsomely well represented. In history the Greeks are particularly strong. Parnassios has described with great vigour the exploits of Bulgaris. Theophrastus' *History of the Revolution* is a masterly work. Philonon has given the Russian side of the revolutionary movements with great earnestness, and nearly every man who took a part in the movements has handed down his recollections, or, as in the case of Colocotronis, who was illiterate, has dictated them to some one who could put them into shape. The Greeks have been particularly active in investigating the history of the Byzantine empire, of the Venetian domination, and of special localities. The history of Papadopoulos is especially valuable in regard to the later periods, and its style is singularly clear and flowing. Along with him should be mentioned Sakellios, Sakellarios, Sathas, Dyzantios, Monastirides, Dragonmizis, Triantaphyllis, and Paspatis. In theology Gieseler stands forth as the first of preachers, Theology occupying the place which Minutius held as a popular orator in the 17th century. Contaginos is well known by his *History of Patriotic Literature down to the Fourth Century*, and by his edition of *Clement's Romanes*. Bialla Philo stands first among Greek philosophers for profoundness and originality. Along with him may be mentioned Vassilios and Benetis. Greeks have also distinguished themselves in medicine, but very frequently they write their scientific

Lav, &c	books in French. They have also produced many treatises on law, political economy, and on mathematics and the physical sciences. Little has been accomplished in the way of original novel-writing. We have seen that Panagiotis and Alexandi Soutos and Rangabé wrote novels, and others have done so likewise, with moderate success.
Fiction	One recent work, " <i>Hikátoria Iasúra</i> ," by Roidos, has gained considerable popularity, and is written in an attractive and vigorous style. Another novelist, Stephanos Xenos, now known to English readers by his work on the Ionian Islands, called <i>East and West</i> . He is the author of a novel called <i>the Devil in Turkey</i> , and he wrote in Greek an interesting account of the Exhibition in London in 1851. Several ladies have distinguished themselves in the field of Greek literature. Especially deserving of mention is Dora D'Alstia, whose work on the <i>Women of the West</i> , contributed to the <i>Pandora</i> and forming a pendant to her <i>Women of the East</i> , written in French, shows remarkable powers of research, exposition, and criticism. The Greeks, as might have been expected, have produced good editions of the classical writers. They have also done much to elucidate the archæology of their country, though most of their works on this subject are written in foreign languages. Among these works especially deserving mention are <i>Antiquities of Athens</i> of Pittakis, in French, the <i>Græciæ antiquæ</i> of <i>August Gell</i> , in German, in German, the <i>Hellenic Architecture</i> , by Rangabé, in German, the <i>Sprache und Inschriften</i> of Attica, by Commanoudis, in modern Greek, and <i>Dolens und its Ruins</i> , by Campanos, in French. The works of Lambros on numismatics are of great value. The Greeks have also contributed much to a knowledge of the ancient Greek language. Asopios has gained a great name in this direction, and the contributions of Constantinos Kontos are very valuable. They have also done much to collect materials for a knowledge of existing dialects. Investigations have been made into the dialects of the Tæconians by Geomones and Néo Loorian by Chalkopoulos.
Female authors	
Archæology	
Philology	

and lists of peculiar words and forms to be found in Cythere, Chios, Cetea, Cyprus, Locri, and other places, have appeared in *Pandora* and other journals. Castellan has written much and well on Latin literature. The Greeks have a very large number of newspapers and journals, if we consider the number of the population, but, as might be expected, their existence is precarious, and many are short lived. Translations abound in modern Greek, especially from the French, but the Greeks have also translated classical Greek literature. The French works of all kinds are translated into Greek, and the translations of Voltaire and Diderot. The translations incline those of Müller and Dindorf's *History of Greek Literature* by Valletta, and Shakespeare's *Romeo and Juliet*, *Hamlet*, and *Macbeth* by Bikelas.

[illegible]

INDEX

[illegible][illegible][illegible][illegible][illegible][illegible]

GREEK CHURCH, THE, or more properly the Eastern Church, is both the source and background of the Western Christianity now in the East, and Greek was the language of the Scriptures and early services of the church, but when Latin Christianity established itself in Europe and Africa, and when the old Roman empire fell in two, and the eastern half became separate in government, interests, and ideas from the western, the term Greek or Eastern Church acquired gradually a fixed meaning. It denoted the church which included the patriarchates of Antioch, Alexandria, Jerusalem, and Constantinople, and their dependencies. The ecclesiastical division of the early church, at least within the empire, was based upon the civil Constantinian introduction of a new partition of the empire into dioceses, and the church adopted a similar division. The bishop of the chief city in each diocese naturally rose to a pre-eminence, and was commonly called *επίσκοπος*—a title borrowed from the civil jurisdiction. In process of time the common title *patriarch* was restricted to the most eminent of these archbishops, and councils decided which were worthy of the dignity. The council of Nicaea recognized three patriarchs—the bishops of Rome, Alexandria, and Antioch. To these were afterwards added the bishops of Constantinople and Jerusalem. When the empire was divided, there was one patriarch in the West, the bishop of Rome, while in the East there were at first two, then four, and lately five. This geographical fact has had a great deal to do in determining the character of the Eastern Church. It is not a despotic monarchy governed from one centre and by a monarch in whom plenitude of power resides. It is an oligarchy of patriarchs. It is based, of course, on the great body of bishops, but episcopal rule, through the various grades of metropolitan, primate, archbishop, attains to sovereignty only in the five patriarchal thrones. Each patriarch is, within his diocese, what the Gallican theory makes the pope in the universal church. He is supreme, and not amenable to any of his brother patriarchs, but is within the jurisdiction of an oecumenical synod. This makes the Greek Church quite distinct in government and traditions of polity from the Western. It has ever been the policy of Rome to efface national distinctions, but under the shadow of the Eastern Church national churches have grown and flourished. Revolts against Rome have always implied a repudiation of the ruling principles of Ultramontanism, but the schismatic churches of the East have always reproduced the ecclesiastical polity of the church which they have deserted.

The Greek Church, like the Roman, soon spread out far beyond the imperial dioceses which at first fixed its boundaries, but, unlike the Roman, it did not keep for Christianity all the lands it had once laid hold of. What Rome Christianized, with the exception of Africa, remained Christian. The old empire was overrun by the barbarians, but the conquering empire imposed its law and its religion upon its conquerors, and pagan and heretic became in the end Catholic Christians. In the East it was otherwise. The empire maintained itself long and died hard, but its decline and fall meant not merely the overthrow of the supremacy of the emperors of the East, it meant also the destruction of civilization and the submergence of Christianity. In the West, German and Saxon, and Goth and Lombard, became Christian law-abiding peoples. In the East Arab and Kurd, before they swarmed over the Eastern empire, and could never be taught either law or gospel. It is true that the Eastern Church more than made up for her losses by her missionary enterprise, but she never conquered her conquerors, and the historian is too apt to speak of her past glories and forget her present strength. The same reason also makes it difficult to describe, with any accuracy, the extent of the Greek Church. She has shifted her position

so often that to describe her extent at any one period must be misleading. The church never at any one period occupied all the territories she has possessed.

The patriarchate of Constantinople included the imperial dioceses of Pontus, Asia, Thrace, and Eastern Illyria—*ἡ εὐρώπη*, speaking roughly, the greater part of Asia Minor, European Turkey, and Greece, with a small portion of Austria. The imperial diocese of Pontus was governed by the exarch of Cæsarea, who ruled over thirteen metropolitans with more than 100 suffragans, now there are nine metropolitans (Kassareh, Izik, Angour, Nikaia, Amasia, Iamni, Hadikio, Broussa, Nizak), and one archbishopric (Tchoukour), but the suffragans seem to have disappeared. Asia was governed by the exarch of Ephesus, who ruled over twelve metropolitans with more than 350 suffragan bishops. Of these there remain Ephesus, with its suffragans Aidene and Chamae, Smyrna, Artaki, Marmora, Allah Shichi, Ithodee, Samos, Khio, Cos, Paronaxia, Santourne, Andio, Milo, Leco, Scarpanto, Sephanto, Imbro, Lemno, Metelini, Molivo, Myra, and Konieli. In Asia Minor the church maintains but a small remnant of her former greatness, in Europe it is otherwise. The old outlines, however, are effaced wherever the Christian races have emancipated themselves from the Turkish rule, and the national churches of Greece, Servia, and Roumania have reorganized themselves on a new basis. Where the Turkish rule still remains, the church retains her old organization, but greatly impaired. The national churches of Russia, Georgia, and Armenia are offshoots from the patriarchate of Constantinople, but quite independent of its jurisdiction.

The patriarchate of Antioch has undergone most changes in extent of jurisdiction, arising from the transfer of seat to Jerusalem, from the progress of the schismatic churches of the East, and from the conquests of the Mahometans. At the height of its power the patriarch of Antioch ruled over 12 metropolitans and 250 suffragan bishops. In the time of the first crusade 153 still survived, now there are scarcely 20. Most of those that remain are called either metropolitan or archiepiscopal sees, but they have few or no suffragans. In Syria there are still Antioch, Aleppo, Ladochah, and Arcadia, in Phœnicia, Tyre and Sidon, Beyrout, Tripoli, Emessa, and Heliopolis, in Chilia, Adana, in Syria, Epiphania, in Iacania, Seleucia, in Cyprus, Famagosta, with Piscope, Baflo, Neapolis, Limasol, and Nicosia as suffragan sees. Cyprus has been independent of Antioch, however, since the council of Ephesus. Antioch also had jurisdiction beyond the bounds of the empire over Chaldea and India, and the missionaries of Antioch seem to have preached Christianity in the borders of China. The Chaldean Church now, however, is almost entirely Nestorian. The Thomas Christians of India do not belong to the Orthodox Greek Church. In Syria the Jacobites are more numerous than the Orthodox, while the Maronites of Lebanon have become subject to Rome.

In the earlier period of the church, ecclesiastical followed civil divisions so closely that Jerusalem, in spite of the sacred associations connected with it, was merely an ordinary bishopric dependent on the metropolitan of Cæsarea. Ambitious prelates had from time to time endeavoured to advance the pretensions of their see, but it was not until the council of Chalcedon, in 451, that Jerusalem was made a patriarchate with jurisdiction over Palestine. From this time on to the irroad of the Saracens, the patriarchate of Jerusalem was highly prosperous. It ruled over three metropolitans with eighty suffragans. The modern patriarch has seven suffragans, all of whom enjoy the titles of metropolitan or archbishop—Cæsarea, Scythopolis (Bethshan), Petra, Ptolemais, Sinai, Nablous, Samaria. The patriarchs, however, are non-resident (they live in Constantinople), and the primate of Palestine is the metropolitan of Cæsarea.

The patriarch of Alexandria in ancient times possessed much more power than the others, and the church ruled by him was much more centralized. He had no metropolitans. His hundred suffragans were ordinary bishops. This perhaps in part accounts for the decay of the Orthodox church in Egypt, at present there is no bishop but the patriarch. The Christians in Egypt are for the most part Monophysites. The church of Nubia has been blotted out. The church of Ethiopia or Abyssinia is Monophysite, and acknowledges the Jacobite patriarch of Cairo.

HISTORY—Controversies and Schemes.—To describe the controversies of the Greek Church is to write the history of the church of the first five centuries, in a short sketch like this all that can be done is to mention those causes of division which led (1) to the formation of the schismatic churches of the East, and (2) to the open rupture with Latin Christianity.

The great dogmatic work of the Greek Church was the definition of that portion of the creed of Christendom which concerns *theology proper*,—the doctrines of the essential nature of the Godhead, and the doctrine of the Godhead in relation with manhood in the incarnation, while it fell to the Latin Church to define *anthropology*, or the doctrine of man's nature and needs. The controversy which concerns us is all about the person of Christ, the Theanthropos, for they alone are represented in the schismatic churches of the East. These controversies are more easily described, at least for our purpose, by reference to the oecumenical councils of the ancient and undivided church.

Rise of Sects.—All the churches of the East, schismatic as well as orthodox, accept unreservedly the decrees of the first two councils. The schismatic churches protest against the additions made to the creeds of Nicea and Constantinople by succeeding councils. The Niceo-Constantinopolitan creed declared that Christ was *consubstantial* (*ὁμοούσιος*) with the Father, and that He *had become man* (*ἐνανθρώπησας*). Disputes arose when theologians tried to explain the latter phrase. These differences took two separate and extreme types, the one of which forcibly separated the two natures so as to deny anything like a real union, while the other insisted upon a mixture of the two, or an absorption of the human in the divine. The former was the creed of Chalcedon and the latter the creed of Egypt, Chalcedon was the home of Nestorianism, Egypt the land of Monophysitism. The Nestorians accept the decisions of the first two councils, and reject the decrees of all the rest as unwarranted alterations of the creed of Nicea. The Monophysites accept the first three councils, but reject the decree of Chalcedon and all that come after it.

The council of Ephesus, the third oecumenical, had insisted upon applying the term *Theotokos* to the Virgin Mary, and this was repeated in the symbol of Chalcedon, which says that Christ was born of the Virgin Mary, the *Theotokos*, "according to the manhood." The same symbol also declares that Christ is "to be acknowledged in two natures, indivisibly and inseparably." Hence the Nestorians, who insisted upon the unity of the natures to such a degree as to lose sight of the duality of the person, and who rejected the term *Theotokos*, repudiated the decrees both of Ephesus and of Chalcedon, and upon the promulgation of the decrees of Chalcedon formally separated from the church. Nestorianism had sprung from an exaggeration of the theology of the school of Antioch, and the schism weakened that patriarchate and its dependencies. It took root in Chalcedon, and became very powerful. No small part of the literature and science of the Mahometan Arabs came from Nestorian teachers, and Nestorian Christianity spread widely. "It was successfully preached to the Bactrians, the Huns, the Persians, the Indians, the Persarmenians, the Medes, the Elamites. The barbaric churches from the Gulf of Persia

to the Caspian Sea were almost infinite. The Malabar coast and the Isles of the Ocean, Zocotia and Ceylon, were peopled with an innumerable number of Christians. The missionaries of Balch and Samarcand pursued without fear the footsteps of the roving Tartars, and insinuated themselves into the valleys of the Tians and the banks of the Selenga." Their principal bishop took the title of patriarch of Babylon. His seat was later removed to Baghdad and then to Mosul, it is now at Julamaik in Kurdistan. In the 11th century he ruled over twenty-five metropolitans, and his jurisdiction extended from the Tigris to China, from Lake Baikal to South India. Persecutions weakened the church, Timur almost exterminated it. In the 16th century a schism occurred, many of the Nestorians yielded obedience to Rome. The Roman Nestorians are usually called Chaldeans, though all lay claim to the title. At present the patriarch rules over two metropolitans and sixteen suffragan bishops. The Nestorians dwell principally in Kurdistan, though many are found in Mesopotamia and in India. In the latter country they are numerous on the Malabar coast, and are called Thomas Christians.

The council of Chalcedon, the fourth oecumenical, declared that Christ is to be acknowledged "in two natures—unconfusedly, unchangeably," and therefore decided against the opinions of all who either believed that the divinity is the sole nature of Christ, or who, rejecting this, taught only one composite nature of Christ (one nature and one person, instead of two natures and one person). The advocates of the one nature theory were called Monophysites, and they gave rise to numerous sects, and to at least three separate national churches—the Jacobites of Syria, the Copts of Egypt, and the Abyssinians of Ethiopia.

The term "Jacobite" (from Jacobus Baradaeus, a Syrian theologian) is properly confined to the Syrian Monophysites, but is sometimes used to denote all the various divisions of this heresy. The Jacobites therefore accept the first three councils and reject those that follow. The Armenian Church does the same, and it is common to class the Armenians with the Jacobites, while some theologians have made them more identical than the Jacobites of Syria and Egypt (*Neale, Holy Eastern Church, Patriarchate of Alexandria*, pp. 8-10). This, however, seems a wrong opinion, and the Armenians ought to be reckoned as Orthodox (see ARMENIAN CHURCH). Apart, however, from theological criticism, the Jacobites are arranged under three patriarchates—Antioch, Alexandria, and Armenia. Antioch and Alexandria have intercommunion, but Armenia, in spite of times of reconciliation, stands apart. Under the patriarch of Alexandria is the metropolitan of metropolitans of Abyssinia, and under the patriarch of Antioch the metropolitan of the East. The Jacobites, or Copts of Egypt, greatly outnumber the members of the Orthodox Greek Church there. The patriarch assumes jurisdiction over Egypt, Jerusalem, Nubia, Abyssinia, and the Pentapolis. He now resides in Cairo, and is chosen by lot in a council of all the bishops from a number of monks recommended by four convents to whom belongs this privilege. He has for suffragans the bishops of Menout, Sherkeyeh, Behnesa, Fayoum, Minyeh, Senabou, Mansfoult, Siout, Abuteq, Assoum, Rene, Kauss and Nekada, and Khartoum. He has besides jurisdiction over twenty-six monasteries, and rules nominally over the Church of Abyssinia.

The Syrian Jacobites also form a patriarchate—the patriarchate of Antioch. While Antioch belonged to the empire, the persecution of the state drove the Jacobite patriarch from the city. He settled at Amid, now called Caramlik, which is still the ecclesiastical centre. The second dignity is the metropolitan (fruitbearer) of the East, who was originally a missionary bishop to the regions east of the Tigris. He is now settled at Mosul. The Syrian Jacobites

could at one time boast 20 metropolitans and 103 bishops, now there are only 5 metropolitans (Caramit, Mosul, Measdin, Aleppo, and Jerusalem) without suffragans.

The decisions of Chalcedon, which were the occasion of the formation of all these sects outside, did not put an end to Christological controversy inside the Orthodox Greek Church. The most prominent question which emerged in attempting to define further the person of Christ was whether the will belonged to the nature or the person, or, as it came to be stated, whether Christ had two wills or only one. The church in the sixth oecumenical council at Constantinople declared that Christ had two wills. The Monothelites refused to submit, and the result was the formation of another schismatic church—the Maronite Church of the Lebanon range. The Maronites, however, in the 19th century were reconciled to Rome, and cannot now be said to belong to the Greek Church.

Conflict with Rome—The relation of the Greek Church to the Roman may be described as one of growing estrangement from the 5th to the 11th century, and a series of abortive attempts at reconciliation since the latter date. The estrangement and final rupture may be traced to the overbearing pretensions of the Roman bishops and to Western innovation in the doctrine of the Holy Spirit, accompanied by an alteration of creed. In the early church three bishops stood forth prominently, principally from the political eminence of the cities in which they ruled—the bishops of Rome, Alexandria, and Antioch. The transfer of the seat of empire from Rome to Constantinople gave the bishops of Rome a possible rival in the patriarch of Constantinople, but the absence of an overawing court and meddling statesmen did more than recoup the loss to the head of the Roman Church. The theological calumnies of the West, amid the violent theological disputes which troubled the Eastern patriarchates, and the statesmanlike wisdom of Rome's greater bishops, combined to give a unique position to the pope, which councils in vain strove to shake, and which in time of difficulty the Eastern patriarchs were fain to acknowledge and make use of, however they might protest against it and the conclusions deduced from it. But this pre-eminence, or rather the Roman idea of what was involved in it, was never acknowledged in the East, to press it upon the Eastern patriarchs was to prepare the way for separation, to insist upon it in times of irritation was to cause a schism. The theological genius of the East was different from that of the West. The Greek theology had its roots in Greek philosophy, while a great deal of Western theology was based on Roman law. The Greek fathers succeeded the Sophists, the Latin theologians succeeded the Roman advocates (Stanley's *East Ch.*, ch. 1). This gave rise to misunderstandings, and at last led to two widely separate ways of regarding and defining one important doctrine—the procession of the Holy Spirit from the Father or from the Father and the Son. Political jealousies and interests intensified the disputes, and at last, after many premonitory symptoms, the final break came in 1054, when Leo IX smote Michael Cerularius and the whole of the Eastern Church with an excommunication. There had been mutual excommunications before, but they had not resulted in permanent schisms. "It was scarce two centuries since anathemas had been exchanged between Adrian I and Photius, between Photius and Nicholas I. The sixth council had formally anathematized Honorius I. by name. There had been great violence of language in the 6th century between Gregory I and John the Faster, and not many years before that the name of Vigilius had been deliberately erased from every one of the diptychs of the Eastern Church" (Foulkes's *Christianism's Divisions*, 1 § 17). Now, however, the separation was final, and the ostensible cause of its finality was the introduction by the

Latins of two words *filioque* into the creed. It is this addition which was and which still remains the permanent cause of separation. Foulkes has pointed out in his second volume (ch. 1-3) that there was a resumption of intercourse more than once between Rome and Constantinople after 1054, and that the overbearing character of the Norman crusaders, and finally the horrors of the sack of Constantinople in the fourth crusade, were the real causes of the permanent estrangement. It is undeniable, however, that the *filioque* question has always come up to bat the way in any subsequent attempts at intercommunion. The theological question involved is a very small one, but it brings out clearly the opposing characteristics of Eastern and Western theology, and so has acquired an importance far beyond its own worth. The question is really one about the relations subsisting between the persons of the Trinity and their hypostatical properties. The Western Church affirms that the Holy Spirit "proceeds from" the Father and from the Son. It believes that the Spirit of the Father must be the Spirit of the Son also. Such a theory seems alone able to satisfy the practical instincts of the West, which did not concern itself with the metaphysical aspect of the Trinity, but with Godhead in its relation to redeemed humanity. The Eastern Church affirms that the Holy Spirit proceeds from the Father only. The Eastern theologians think that the Western double processions degraded the Deity and destroys the perfection of the Trinity. The double procession, in his eyes, means two active principles (*airiai*) in the Deity, and it means also that there is a confusion between the hypostatical properties, a property possessed by the Father and distinctive of the First Person is attributed also to the Second. This is the theological, and there is conjoined with it an historical and moral dispute. The Greeks allege that the addition of the words *filioque* was made, not only without authority, and therefore unauthoritatively, but also for the purpose of forcing a rupture between East and West in the interests of the barbarian empire of the West.

Attempts at reconciliation were made from time to time afterwards, but were always wrecked on the two points of papal supremacy, when it meant the right to impose Western usages upon the East, and of the addition to the creed. First there was the negotiation between Pope Gregory IX and the Greek patriarch Germanus. The Latin conditions were practically recognition of papal jurisdiction, the use of unleavened bread enforced on the Greeks, and the Greeks to be permitted to omit *filioque* on condition that they burnt all books written against the Western doctrine. The Greek patriarch refused the terms. Then came negotiations under Innocent IV and Clement IV, in which the popes proposed the same conditions as Gregory IX, with additions. These proposals were rejected by the Greeks, who regarded them as attempts to enforce new creeds on their church.

The negotiations at the council of Lyons (1274) were, strictly speaking, between the pope and the Greek emperor, and were more political than ecclesiastical. Michael Palaeologus ruled in Constantinople while Baldwin II, the last of the Latin emperors, was an exile in Europe. Palaeologus wished the pope to acknowledge his title to be emperor of the East, and in return promised submission to the papal supremacy and the union of the Greek with the Latin Church on the pope's own terms. This enforced union lasted only during the lifetime of the emperor. The only other attempt at union which requires to be mentioned is that made at the council of Florence. It was really suggested by the political weakness of the Byzantine empire and the dread of the approach of the Turk. John Palaeologus the emperor, Joseph the patriarch of Constantinople, and several Greek bishops came to Italy and appeared at the council of Florence—the papal council, the rival of the

council of Basel. As on former occasions the Greeks were at first deceived by false representations, they were betrayed into recognition of papal supremacy, and tricked into signing what could afterwards be represented as a submission to Western doctrine. The natural consequences followed,—a repudiation of what had been done, and the Greek bishops on their way home took care to make emphatic their ritualistic differences from Rome. Soon after came the fall of Constantinople, and with this event an end to the political reasons for the submission of the Greek clergy. Rome's schemes for a union which meant an unconditional submission on the part of the Greeks did not cease, however, but they were no longer attempted on a grand scale. Jesuit missionaries after the information stirred up schisms in some parts of the Eastern Church, and in Austria and Poland many of the Greeks were compelled to submit themselves to the see of Rome. The result of these schemes has been what is called the *Unia*, or the United Greeks. These various unions have commonly arisen from dissensions among the Greeks themselves when a position of the dissentients have made submission to Rome. Rome commonly promised to allow them to enjoy their own liturgies and rites of worship, but usually broke her promises. This was done so systematically that the college of the Propaganda prints what profess to be the old liturgies of the Eastern churches, which are really so interpolated as to bring them surreptitiously into harmony with the Western rites. This is done so unreservedly that it is impossible to trust to any professedly Eastern creed or service-book printed at the office of the Propaganda in Rome.

Diffinitation of National Churches included in the Orthodox Greek Church.—Mr. Emley, in his *History of Greece*, has shown that there has been always a very close relation between the church and national life. Christianity from this first connected itself with the social organization of the people, and therefore in every province assumed the language and the usages of the locality. In this way it was able to command at once individual attachment and universal power. This feeling died down to some extent when Constantine made use of the church to consolidate his empire. But it revived under the persecution of the Arian emperors. The struggle against Arianism was not merely a struggle for orthodoxy. Athanasius was really at the head of a national Greek party resisting the domination of a Latin-speaking court. From this time onwards Greek patriotism and Greek orthodoxy have been almost convertible terms, and this led naturally to revolts against Greek supremacy in the days of Justinian and other emperors. Dean Stanley is probably correct when he describes the heretical churches of the East as the ancient national churches of Egypt, Syria, and Armenia in revolt against supposed innovations in the earlier faith imposed on them by Greek supremacy. In the East, as in Scotland, the history of the church is the key to the history of the nation, and in the freedom of the church the Greek saw the freedom and supremacy of his race. For this very reason Orthodox Eastern Christians of alien race felt compelled to resist Greek domination by means of independent ecclesiastical organization, and the structure of the church rather favoured than interfered with the coexistence of separate national churches professing the same faith. Another circumstance favoured the creation of separate national churches. While the Greek empire lasted the Greek emperors had a right of investiture on the election of a new patriarch, and this right was retained by the Turkish sultans after the conquest of Constantinople. The Russian people, for example, could not contemplate with calmness as the head of their church a bishop appointed by the hereditary enemy of their country. In this way the jealousies of race and the necessities of nations have produced various national churches which are

independent or autocephalous, and yet are one in doctrine with the Orthodox Greek Church. The most important of these are the churches of Russia, Georgia, Serbia, Roumania, Greece, and Montenegro. The churches of Russia and Georgia have been united.

The Church of Russia dates from 988, when Prince Vladimir Russian and his people accepted Christianity. The metropolitan who was subject to the patriarch of Constantinople, resided at Kiuff on the Dnieper. During the Tartar invasion the metropolitan was destroyed, and Vladimir became the ecclesiastical capital. In 1320 the metropolitan moved from his seat at Moscow. In 1583 Joseph, patriarch of Constantinople, raised Job, 46th metropolitan, to the patriarchal dignity, and the seat was afterwards confirmed by a general council of the East. In this way the Russian Church became autocephalous, and its patriarch had supreme power. In 1721 Peter the Great forbade the election of a new patriarch, and in 1721 he established the Holy Governing Synod to supply the place of the patriarch. This body now governs the Russian Church, and consists of five or six bishops, one or two other ecclesiastics of dignity, and several laymen, all appointed by the emperor. The Church of Georgia, which has existed from a very early period, and was independent first on the patriarch of Antioch and then on the patriarch of Constantinople, has since 1801 been incorporated in the Russian Church. Its head, the archbishop of Tiflis, is a member of the Holy Governing Synod, with the title of exarch, and having under him four suffragan bishops in twelfth century for ecclesiastical purposes into six classes, each of which is ruled over by a bishop. These are the three classes of the first class, ruled by the metropolitans of Kiuff, Novgorod and St. Petersburg, and Moscow. The steady increase of the Russian Church has made it difficult to deal with so many the number of bishops belonging to the three classes, but, according to the report presented to the Holy Governing Synod in 1876, there are, in addition to the three classes of the first class, twenty, and of the second class, thirty of the third, and six vicarials. These sixty three bishops possess diocesan authority, and these are besides, exceeding the estimate of Georgia, fifty six bishops ruling over monasteries.

The Church of Serbia has undergone great changes. In medieval Serbian times, when Serbia was a strong kingdom, the head of the church invariably held the title and authority of patriarch. In 1810, when Kara George achieved the independence of the kingdom, the archbishop of Calowitz in Hungary was recognized as the head of the church, but in 1830 the national church was reconstituted and declared to be autocephalous. In 1838 the seat of government was removed to Belgrade, and the metropolitan of Belgrade is now the head of the Serbian Church, though his right is still disputed by the archbishop of Calowitz. He has under him as suffragans the bishops of Shabatz, Ostretsk, and Uclure, and the last of whom resides at Kusanowitz. Election to the episcopate is subject to the veto of the prince and of the patriarch of Constantinople. The extension of Serbia under the provisions of the treaty of Berlin will probably cause some ecclesiastical changes.

Before the union of the two provinces of Moldavia and Wallachia, Russia the Orthodox Greek Church was ruled by two metropolitans—the one at Jassy and the other at Bucharest. Since the independence of the united provinces there has been a long continued conflict, which led for its design, not merely to throw the supremacy of the patriarch of Constantinople, but to curb the influence of the higher clergy, and to assert the pre-eminence of the Slavonic over the Greek element. The result has been that the state, and by the lower clergy and the people, has thrown off the supremacy of Constantinople, united the church under one metropolitan of Roumania, who has under him the metropolitan of Moldavia and six bishops, non-located by property, most of the convents, and the Greek influence, published his liturgy either in the Slavonic or in the Roumanian language, and asserted the supremacy of the state.

The constitution of the Church of Modern Greece is the result of Hellenism, the peculiar position of the patriarch of Constantinople. The idea of liberation was sympathized in, not merely by the inhabitants of Greece, but by all the Greek-speaking Christians in the East. But the patriarch was in the hands of the Turks, he had been appointed by the sultan, and he was compelled by the Turkish authorities to ban the movement for freedom. When the Greeks achieved independence they refused to be subject ecclesiastically to a patriarch who was nominated by the sultan (June 9, 1828), and, to add to their difficulties, there was in the country twenty-two bishops who had been consecrated by the patriarch, twelve bishops who had been consecrated irregularly during the war, and about twenty bishops who had been deprived of their sees during the troubles—such a situation was to be put in order. The Greek authorities, under the circumstances the Government and people resolved that there should be ten diocesan bishops and forty additional provisional sees. They also resolved that the church should be governed after the fashion of the Russian Church by a synod, and they desired that the king of Greece was to be head of the church. All these ideas were

The Church of Christ is the fellowship of all: I HOPE YOU ACCEPT AND PREFER ALL THE APOSTLES OF FAITH UNANIMITY BY THE APOSTLES AND APPROVED BY GENERAL SYNODS. *Without this visible Church there is no salvation.* It is under the shining influence of the Holy Ghost, and the Holy Spirit, as *medium* of faith. Specially appointed persons are necessary in the service of the Church, and they form in a *threefold order*, distinct *que distincta* from each other: *Christians, of Bishops, Priests, and Deacons.* THE FOUR *PRIESTHOODS*, OF WHICH RIGHTEOUS, HAVE THE HIGHEST RANK AMONG THE BISHOPS, AND THE BISHOPS, *united in a General Council* represent the Church and infallible *decide*, under the guidance of the Holy Ghost, all matters of faith and ecclesiastical life. All members of Christ must be equally called and appointed to them, and are consecrated by the sacrament of *orders*. *Bishops must be unmarried, and priests and deacons must not be married.* To all priests in common belongs, besides the preaching of the word, the administration of the SIX SACRAMENTS, — BAPTISM, CONFIRMATION, PRAYERS, EUCHARIST, MATRIMONY, UNCTION OF THE SICK. The bishops alone can administer the sacrament of *orders*.

Sacramental ceremonies are part of the divine service, most of them have apostolic origin, and those connected with the sacrament must not be omitted by private under pain of mortal sin.

LITURGY AND WORSHIP.—The ancient liturgies of the Eastern Church were very numerous, and have been frequently classified. Neale makes three divisions—the liturgy of Jerusalem or of St James, that of Alexandria or of St Mark, and that of Edessa or of St Thomas;—and Daniel substantially agrees with him. The same passion for uniformity which suppressed the Gallican and Mozarabic liturgies in the West led to the almost exclusive use of the liturgy of St James in the East. It is used in two forms, a shorter revised by Chrysostom, and a longer called the liturgy of St Basil. This liturgy and the service generally are either in Old Greek or in Old Slavonic;—and frequent disputes have arisen in particular districts about the language to be employed. Both sacred languages differ from the language of the people, but it cannot be said that in the Eastern Church worship is conducted in an unknown tongue;—"the actual distinction," says Neale, "may be about that between Chaucer's English and our own."

MONASTIC LIFE.—Monastic life was introduced into Christianity in the East, and has always remained a prominent feature in Greek Christianity. The monks usually follow the rule of St Basil, but some monasteries, notably that of Sinai, obey the rule of St Anthony. The monks are of three classes — *novices*, who live together in a monastery ruled over by a *hypodyacon* or *decan*, *anachorites*, who live either in a cloister apart from the other monks or among the laity, and *hermits*, who are hermits. The nuns, virgins or widows, all follow the rule of St Basil. There are three great convents—at Jerusalem, Sinai, and Mount Athos, each has a great number of daughter monasteries throughout the East. Many monasteries are presided over by bishops, and many monks are in priests' and deacons' orders. Monks alone are eligible for election to bishoprics and the higher offices in the Eastern Church.

Number of Adherents—There can only be given approximately —

Orthodox Greek Church in Turkey	10,000,000
" " Roumania	4,529,000
" " Servia	1,845,000
" " Montenegro	180,000
" " Greece	1,810,000
" " Austria	8,900,000
" " Russia (including Poland, Siberia, and the Caucasus)	68,000,000
	79,814,000

To these may be added —

Russian Dissenters	1,067,000
Armenians	3,000,000
Nestorians (including the Thomas Christians of India)	860,000
Syrian Jacobites	90,000
Copts	120,000
Abyssinians	1,200,000
	5,829,000
United Greeks (chiefly in Austria and Poland)	4,870,000

See the common books on Church History, as those of Neander, Gieseler, Robertson, &c. Special mention may be made of Schœtzke's *Christliche Kirchengeschichte*, and the many collections of councils, e.g., Mansi's or, for English readers, Halket's *History of the Councils*, translated in Clark's series. For the controversies which gave rise to the schismatic churches, consult F. O. Baur, *Die Christliche Lehre von der Dreieinigkeit*, Dornet, *History of the Doctrine of the Person of Christ*, translated in Clark's series, J. H. Newman, *The Arians of the Fourth Century*, Swinburn, *The Apostolic and Nicene Creeds*. For the Ptolemaic controversy, Welch, *Historia Controversiarum de Processu Spiritus Sancti*, and the works of Swete and Lagrange, may be referred to, also Schœtzke's *History of the Creeds of Christendom*. The following list, devoted specially to the history and condition of the Eastern Church—*—M. Le Quen, Oriens Christianus*; Asseman, *Bibliotheca Orientalis*, Stirley's *Eastern Church*, above all, J. M. Neale, *The Holy Eastern Church*, *History of the Eastern Church*, 5 vols., *Palimpsests of Alexandria*, 5 vols., and, published posthumously in 1873, *Palimpsests of Antioch*, 1 vol.) For liturgy, see Daniel, *Code Liturgique*, *Code des Liturgies*, 4 vols., 1817-55, and the shorter works of Neale and Little, Rannald, *Collegio Liturgiarum*, *Orist*, Leo Allardus, *De liturgiis*, *De liturgiis*, *De liturgiis*, *De liturgiis*. For hagiology, see Daniel, *Thesaurus Hagiologicus*, 4 vols., and Neale's *History of the Eastern Church*, and for creeds, the collections of Kummel, Grass, and Schell.

GREEK EMPIRE. See GREECE, p. 114 *sup*.
GREEK FIRE. is properly the name applied to the inflammable and destructive compounds used in warfare in the Middle Ages, and particularly by the Byzantine Greeks at the sieges of Constantinople. It was the precursor of gunpowder, and of such modern compositions as dynamite and emulsion, and was frequently converted to gunpowder for many years after its invention. But combustible mineral substances were employed in war much earlier than the Middle Ages. Greek fire has borne the names wildfire, maritime fire, wet fire, fire-rain, called by the French *feu grégeois*, by the Germans *griechisches Feuer*, it was "the oil of cruel fire" of the Chinese, the *oleum incendiarium* of the Romans, and the *rup typh*, liquid fire, of the Greeks. Procopius designates it as *Medice's oil*. Cinnamus (12th century) describes it as *rup typh*, Median fire, the black clays of Media and Persia supplying the principal component. Used chiefly at sieges and in naval engagements, it was poured from caldrons and ladles on the besiegers and their engines, or vomited through long copper tubes from the mouths of hideous figures set in the prow of ships. Sometimes flax was twisted and saturated with the liquid, then fired, and projected on arrows, lances, and javelins. At sea it was often flung in pots and phials. The heavy ballists and other military engines were poised into the service in early times for scattering this destructive compound in large quantities, often in barrels. Owing to the viscid nature of Greek fire it adhered to whatever it touched. It is described as producing a thick smoke, a loud explosion, and a fierce flame, and as being quickened by the element of water. Sea-water is specially mentioned as intensifying its inflammability, and whenever it fell among ignitable materials terrible havoc was occasioned. The sight and sound of the engine discharging the torrent of fire caused dismay into many a warrior's breast. The devastating consequences pictured by early writers are probably overdrawn, but there can be no doubt that they were formidable. Liquid fire has been used in warfare from very remote times, as may be seen in the Assyrian bas-reliefs in the British Museum. Greek fire, properly so called, is said to have been employed for the first time against the Saracens in the siege of Constantinople, 673-679, the inventor being a Syrian named Callinicus. The art of compounding Greek fire was concealed at Constantinople with the most jealous care, indeed it was to Greek fire, while the secret of its manufacture was kept, that the city owed in great measure its safety. In 1755 two Frenchmen, Gaubert and Dupré, are reported to have rediscovered the art so carefully concealed by the Byzantine Greeks, but they were prohibited from making it known. Various projects for the use of this or

similar preparations have been advocated in recent times. The ingredients and relative proportions of the composition are not exactly known, the secret having been very successfully preserved. The Syrian historian Michael applies the name naphtha to the "newly invented" Greek fire, and this probably was the destructive agent of the Assyrians, Persians, and other Eastern nations, springs of naphtha abounding in their territories. According to the author of *L'Esprit des Croisades*, Greek fire was compounded of the gum of the pine and other resinous trees reduced to powder, with the addition of bitumens, naphtha, and other bitumens. Painful substances were included, such as the water of a particular fountain in the East, duck's grease, &c. Flar Bacon mentions two of the ingredients, sulphate and sulphur, but conceals the rest. Giambattista Forti states that Greek fire is made by boiling together yellow charcoal, salt, ardent aqua vite, sulphur, pitch, frankincense, threads of soft Ethiopian wool, and camphor. In a Spanish MS of the 13th century in the Bodleian library a different recipe is given, and others will be found in the *Libri apud a Muro Greco prescriptus*, &c., Sloane MS (Brit Mus.) 323, in the Sloane MS 7, *Modus tarentis vapens grecum*, &c. From all that has been said it appears that naphtha—otherwise petroleum, rock oil, or Rangoon tar—and sulphur, and sometimes nitre, were the principal constituents, and the use of these, or two of them, in varying quantities, with the charcoal mentioned by Forti, no doubt gave birth to gunpowder. An invention by Nuxeto composed benzol and potassium, in the proportion of 600 to 1, placed in a glass vessel, and Disney's is believed to have included a solution of phosphorus in sulphide of carbon or chloride of sulphur. But of all the spontaneously combustible liquids, Davson's Lakodyl, $\Lambda_2(\text{OH})_2$, is probably the most deadly, while it is far in advance of the old Greek fire as a destroyer of life. A combustible used at the siege of Charleston, U.S., in 1863 consisted of (1) saltpetre, sulphur, and lampblack, pressed into small tubes, and (2) coal tar naphtha, placed in shells or pumped through hose. The best military authorities appear now to agree that Greek fire is unsuitable for purposes of war, and comparatively little use has been made of it in recent times.

Physik*, 1879, *Revue Scient. Jour n. xiv*, *Scientist*, *Frégate Ixopone*, 1868, and the writings of the Byzantine historians.

HORACE GREELEY

Copyright, 1879, by Charles Scribner's Sons

HORACE GREELEY, an eminent American editor, was born at Amherst, New Hampshire, February 3, 1811. His parents were of Scotch-Irish descent, but the ancestors of both had been in New England for several generations. He was the third of seven children. His father, Zachariah Greeley, owned a farm of 50 acres of stony, sterile land, from which a bare support was wrung. Horace was a feeble and precocious lad, taking little interest in the ordinary sports of childhood, leaning to read before he was able to talk plainly, and being the prodigy of the neighbourhood for accurate spelling. Before he was ten years old his father, through bad management and endorsing for his neighbors, became bankrupt, and his home was sold by the sheriff, while Zachariah Greeley himself fled the State to escape arrest for debt. The family soon removed to West Haven, Vermont, where, all working together, they made a scanty living as day

Labourers. Horace Greeley from childhood desired to be a printer, and when barely eleven years old, tied to be taken as an apprentice in a village office, but was rejected on account of his youth. After three years more with the family as a day labourer at West Haven, he succeeded, with his father's consent, in being apprenticed in the office of *The Northern Spectator*, at East Poultney, Vermont. Here he soon became a good workman, developed a passion for politics, and especially for political statistics, came to be depended upon for more or less of the editing of the paper, and was a figure in the village debating society. He received only \$40 a year, but he spent almost nothing himself, and sent most of his money to his father. In his twentieth year *The Northern Spectator* was suspended. Meantime his father had removed to a small tract of wild land in the dense forests of Western Pennsylvania, 30 miles from Erie. The released apprentice now visited his parents, and worked for a little time with them on the farm, meanwhile seeking employment in various printing offices, and, when he got it, giving nearly his whole earnings to his father. At last, with no further prospect of work nearer home, he started for New York. He travelled on foot and by canal boat, entering New York in August 1831, with all his clothes in a bundle carried over his back with a stick, and with but \$10 in his pocket. More than half of this sum was expended in the first made vain efforts to find employment. Many refused, in the belief that he was a runaway apprentice, and his poor, ill-fitting apparel and rustic look were everywhere greatly against him. At last he found work on a 32mo New Testament, set in agate, double columns, with a middle column of notes in pearl. It was so difficult and so poorly paid that other printers had all abandoned it. He barely succeeded in making enough to pay his board bill, but he finished the task, and thus found subsequent employment easier to get.

In January 1838 Greeley formed a partnership with Francis V. Root, a fellow workman. They combined capital amounting to \$150. Proceeding then type on credit, they opened a small office, and undertook the printing of the first cheap paper published in New York. Its proprietor, Dr H. D. Shepley, meant to sell it for one cent, but under the arguments of Greeley he was persuaded to fix the price at two cents. The paper failed in three weeks, the printers only losing \$60 or \$80 by the experiment. They still had a "Bank Note Reporter" to print, and sent good many letters to printers. Within six months Root was dismissed, and his place in law, James Winchester, took his place in the firm. Greeley was now asked by James Gordon Bennett to go into partnership with him in starting *The Herald*. He declined the venture, but became associated with Bennett when Bennett was subsequently taken ill. On 22d of March 1833, Greeley and Winchester issued the first number of *The New Yorker*, a weekly literary and news paper, the firm then supposing itself to be worth about \$3000. Of the first number they sold about 100 copies, of the second, nearly 200. There was an average increase for the next month of about 100 copies per week. The second volume began with a circulation of about 4500 copies, and with a loss on the first year's publication of \$3000. The second year ended with 7000 subscribers, and a further loss of \$2000. By the end of the third year *The New Yorker* had reached a circulation of 9500 copies, and a total loss of \$7000. It was published nearly seven years and was never profitable, but it was widely popular, and it gave Greeley, and other leaders of the movement. On the 6th of July 1836 Greeley married Miss Mary V. Cheney, a Connecticut school teacher, who he had met in a Greenwich (registrar) boarding-house in New York.

During the publication of *The New Yorker* he added to the scanty income which the job printing brought him by supplying editorials to *The Daily Whip* and various other publications. In 1838 he had gained such standing as a writer that he was selected by Thaddeus Weed, William H. Sewall, and other leaders of the Wing party, for the editorship of a campaign paper entitled *The Jeffersonian*, published at Albany. He continued *The New Yorker*, and travelled between Albany and New York each week to edit the two papers. *The Jeffersonian* was a quick and instructive, rather than a vehement campaign sheet, and the Wings believed that it had a great effect upon the elections of the next year. When, on the 2d of May 1840, some time after the nomination by the Wing party of William Henry Harrison for the Presidency, Greeley began

he hoped never to live in a Republic where one section was unjust to the other by boycott." When the war began he urged the most vigorous prosecution of it. The "On to Richmond" appeal, which appeared day after day in *The Tribune*, was unanimously attributed to him, and he was met by his approval, but after the defeat at Bull Run he was widely blamed for it. In 1864 he urged negotiations for peace with representatives of the Southern Confederacy in Canada, and was sent by President Lincoln to confer with them. They were formal to have no sufficient authority. In 1861 he was one of the Lincoln Presidential tickets for New York. At the close of the war, contrary to the general feeling of his party, he urged universal amnesty and impartial suffrage as a basis of reconstruction. In 1867 his friends again wished to elect him to the Senate of the United States, and the indications were all in his favor. But he refused to be elected under any misapprehension of his attitude, and with what his friends thought unecessarily random tactics his opinions, views on universal amnesty at length, just before the time for the election, with the certainty that this would prevent his success. Some months later he signed the bill known as Jackson's Dredge, and that provoked a torrent of public indignation. He had written a popular history of the late war, the first volume having an immense sale and bringing him immensely large profits. The second was just issued, and the subscribers, in their anger, refused by thousands to receive it. The Union League Club, of New York, gave him notice, through its President, John Jay, of a special meeting called to consider his conduct. In an indignation letter he refused to attend the meeting, and challenged the right to discuss his private life. He wrote, "To be a great, enduring party on the hit and with unceasingly engendered by a bloody civil war is as though you should plant a colony on an iceberg which had somehow drifted up to a tropical or our climate. I have no quarrel with the party devoted to the good of human kind, your children will select my going to Richmond and signing that bad bond as the worst act of all. I can feel that you make this a virtue, stand right, and record your judgment as and says. I vote not how few votes with you, not how many vote against me, for I know that the latter will repent it in dust and ashes before three years have passed."

The effort to expel him failed. In 1867 he was elected delegate to the Convention for the revision of the State constitution. In 1869 he was the Republican candidate for State Controller. There was no hint that any one but him was in the running. He was elected, but he received more votes than most of his associates. In 1870 he was nominated for Congress in a Democratic district. His illness prevented his making any campaign, but his nomination increased the Democratic majority from 3700 two years before to about 1000, and he ran 800 ahead of the Republican candidate for Governor.

He was distinguished by the conduct of General Grant's administration, and became its sharp critic. The discontent which he did much to develop ended in the organization of the "Labor Republican" party, which held its National Convention at Cincinnati in 1872, and was confidently expected to nominate Charles Francis Adams for the presidency. Greeley, however, had unexpected strength, especially among the Southern delegates, and on the sixth ballot received 832 votes against 824 for Adams,—immediate changes reducing the latter to still less than 800, and the result being as recorded it stood—Greeley, 452, Adams, 187. For a time the tide of feeling ran strongly in his favour. It was first checked by the action of his life long opponents, the Democrats, who also nominated him in their National Convention. He expected a support, on account of his attitude towards the South and hostility to Grant, but his thought it a mistake to give him their formal nomination. The event proved his wisdom. Many Republicans who had sympathized with him during the administration, and with the declaration of principles adopted at the first convention, were repelled by the position. This feeling grew stronger until the election. His old party associates regarded him as a renegade, and the Democrats gave him a half hearted support. The Democratic canvass was one of unusual bitterness, amounting sometimes to actual enmity. In August, on representations of the "Lumber State" of the contest, he took the field in person, and made a series of campaign speeches, which were in New England and extending throughout Pennsylvania, Ohio, and Indiana, which aroused great enthusiasm, and were regarded at the time by both friends and opponents as the most brilliant continuous exhibition of varied intellectual power ever witnessed in New England. In the canvass General Grant received in the election \$,597,070 votes, Greeley \$,384,079. The only States Greeley carried were Georgia, Kentucky, Maryland, Missouri, Tennessee, and Texas.

He had resigned his editorship of *The Tribune* immediately after the nomination, he now resumed it cheerfully, but it was soon apparent that his powers had been overstrained. For years he had suffered greatly from indigestion. During the intense excitement of the campaign the difficulty increased. Returning home, his campaign tour, he went immediately to the bedside of his dying

wife, and for some weeks had practically no sleep at all. This resulted in an inflammation of the upper membrane of the brain, delirium, and death. He expired on the 29th of November 1872. The funeral was a simple, but impressive occasion. The remains were laid in state in the City Hall, where it was surrounded by crowds of many thousands. The ceremonies were attended by the president and vice president of the United States, the chief justice of the supreme court, and a large number of eminent public men of both parties, who followed the hearse in a solemn procession, preceded by the mayor and other civic authorities, down Broadway. He had been the target of constant attack during his life, and his personal habits, even his dress and mental characteristics, were the subject of endless ridicule. But his death revealed the high regard in which he was generally held as a leader of opinion and faithful public servant. "Our later Franklin" Whittier called him, and it is in some such high his countrymen remember him.

In 1851 Greeley visited Europe for the first time, serving as a journeyman at the Crystal Palace Exhibition, appearing before a committee of the House of Commons on November 12th, and making the special of the stamp duty on advertisements. In 1856 he made a second trip to Europe. In Paris he was arrested on the suit of a sculptor, whose statue had been injured in the New York World's Fair (of which he had been a director), and spent two days in Clukey, of which he gave an amusing account. In 1859 he visited California by the overland route, and had numerous public receptions. In 1871 he visited Texas, and his trip through the southern country, where he had once been sojourning, was an occasion. About 1853 he purchased a farm at Chippewa, New York, where he afterwards habitually spent his Sundays, and experimented in agriculture. He was in constant demand as a lecturer from 1813, when he made his first appearance on the platform, to 1872, before large audiences, and, in spite of his age and management in money matters, received considerable sums, sometimes \$6000 or \$7000 for a single evening's lecturing. He was also much sought for as a contributor to his own signature, to the weekly newspapers, and was sometimes largely paid for these articles. In recognition of his was from boyhood a Universalist, and for many years a conspicuous member of the leading Universalist church in New York.

His published works are—*History of the Republic* (New York, 1850), *Glances at Europe* (1851), *History of the Struggle for Slavery Extension* (1856), *Orations and Journeys to San Francisco* (1860), *The American Republic* (3 vols., Hartford, 1864-66, pp. 648 and 752, 2 vols., New York, 1867), *John Jay's History of the American Republic* (New York, 1867), *What I know of Farming* (New York, 1868), *an edition, with appendix containing an account of his later years, his Arguments on Marriage and Divorce with Robert Estlin O'Connell, and Miscellaneous* (New York, 1878), *Essays on Political Economy* (Boston, 1870), *What I know of Farming* (New York, 1871). He also married his brother in law, John P. Cleveland, in editing *A Political Trifling* (New York, 1860), and supervised for many years the annual issue of *The Whig Almanac* and *The Tribune Almanac*, comprising extensive political statistics.

Lives of Greeley have been written by James Pulton (New York, 1856), new edition, 1858, and Boston, 1872), L. U. Davis (New York, 1873), and L. D. Hugesell (Chicago, 1874). There is also a *Memorial of Horace Greeley* (New York, 1874).

GREEN BAY, a city of the United States, capital of Brown county, Wisconsin, is situated at the head of Green Bay, an inlet on the west shore of Lake Michigan. The bay is 100 miles long, from 15 to 35 miles wide, and of considerable depth. The city stands on the north shore of Fox River, with a small stream across the East River on the other side, its situation affording it a scenic harbour. It is 242 miles N. of Chicago, 114 N. of Milwaukee, and 120 N. E. of Madison, the capital of the State. By the completion of a canal connecting the Fox and Wisconsin rivers at Portage City, Green Bay has become the terminus of the inland water-system which unites the great lakes with the Mississippi and the Gulf of St Lawrence with the Gulf of Mexico. The meanness of Green Bay to the forests of the State makes it a centre of the lumber trade, and it exports annually large quantities of planks, boards, shingles, staves, and headings. It has several other manufactures, an iron furnace, a foundry, machine-shops, sawmills, planing-mills, and breweries. The fishing interests, especially in yellow perch and lake-trout, are important. Three lines of railway and the largest lake steamers minister to its commerce. Though the French formed settlements on the bay as early as 1745, the site of the present city was not laid out until 1830.

and 1835, when the villages of Navasno and Astor were founded. In 1830 these were incorporated under the name of Green Bay, and in 1854 a city charter was granted. It was in 1868 created a bishop's see by Pius IX., and a handsome cathedral church in the Romanesque style has been erected since. The growth of the place has been rapid even for an American city. The population in 1860 numbered 2375, and 4666 in 1870, exclusive of Fort Howard across the river, with its population of 2462, which commercially may well be regarded as part of the city. In 1875 the State census gave 8037 to Green Bay and 3610 to Fort Howard.

GREENE, MAURICE, an English composer, was born in London towards the close of the 17th century (about 1696, it is generally stated). He was the son of a clergyman in the city of London, and soon became a chorister of St Paul's Cathedral, where he studied under Charles King, and subsequently under Richard Brind, organist of the cathedral from 1707 to 1718, whom, on his death in the last named year, he succeeded. Nine years later he became organist and composer to the chapel royal, on the death of Dr Croft. In 1730 he was elected to the chair of music in the university of Cambridge, and had the degree of doctor of music conferred on him. Dr Greene was a voluminous composer of church music, and his collection of *Forty Select Anthems* is a standard work of its kind. He also wrote a *Te Deum*, several cantatas, a mass, *The Judgment of Hercules*, and a pastoral opera, *Phœbe* (1748). He is also among the writers of glees and catches, a form of music peculiar to English composers (see GRAY), and a collection of *Catches and Canons for Three and Four Voices* is amongst his compositions. In addition to this he wrote many occasional pieces for the king's birthday, having been appointed master of the king's band in 1735. But it is as a composer of church music that Greene will be chiefly remembered. It is here that his contrapuntal skill and his sound musical scholarship are chiefly shown. The influence of Handel is, however, discernible in his compositions. With that great master Greene was originally on intimate terms, but his equal friendship for Buononcini, Handel's rival, estranged the German master's feelings from him, and all personal intercourse between them ceased. Greene, in conjunction with Festing and others, originated that excellent institution, the Society of Musicians, for the support of poor artists and their families. He died September 1, 1755.

GREENE, NATHANIEL (1742-1786), an American general, son of a Quaker who followed the joint occupation of a farmer and smith, was born at Potowommet, Warwick county, Rhode Island, May 27, 1742. From his early years he was employed in assisting his father, but he succeeded, notwithstanding this, in acquiring a large amount of general information, and made a special study of mathematics, history, and law. At Coventry, where he removed to take charge of a forge of his own, he was the first to establish a public school, and in 1770 he was chosen a member of the legislature of Rhode Island. Sympathizing strongly with the revolutionists he in 1774 joined the "Kentish Guards," and on this account was expelled from the Society of Friends. In 1775 he was appointed to the command of the contingent of 1000 men raised by Rhode Island, and after joining Washington before Boston he was named brigadier-general. In 1776 he obtained the rank of major-general and accompanied Washington to New Jersey, where he took part in the battles of Trenton and Princeton. At the urgent request of Washington he in 1778 accepted the office of quartermaster-general, on the understanding, however, that he should retain the right to command in the field, a right of which he took advantage at the battle of Monmouth, 24th June of the same year,

and at the battle of Springfield, 23d June 1780. In August following he resigned his office, and on the 21st of December he succeeded Gates in the command of the Southern army. In this position he was soon successful in restoring the demoralized and helpless troops to a condition of thorough vigour and efficiency, and though not always technically victorious in the combats in which he engaged, he conducted operations in such a masterly manner that the enemy gained little advantage from any victories they obtained, and were never able to baffie him in what was essential in his plans. At the beginning of the campaign he detached General Morgan to attack the enemy at Cowpens, with a result that was brilliantly successful. Then followed a series of clever retreats to avoid engaging superior forces, until he deemed himself strong enough to attack the enemy at Guilford Court House, and although he here suffered defeat, the British army a few days afterwards retreated towards Wilmington. After following a short distance in pursuit he changed his line of march, and advancing into South Carolina attacked Lord Rawdon at Camden, and again suffered a defeat. But this reverse also failed to impede his energy, and after capturing a number of forts he again engaged Lord Rawdon at the battle of Eutaw Springs, where, though a drawn combat, resulted in the British abandoning South Carolina. For his services in the campaign he was presented with two pieces of captured ordnance, a British standard, and a gold medal. Georgia and North and South Carolina also made him valuable grants of land. He died from sunstroke at his estate of Mulberry Grove, Savannah, June 10, 1788. *His Life and Letters*, 3 vols., edited by G. W. Greene, were published in 1867-71.

GREENE, ROBERT (1680-1592), dramatist and miscellaneous writer, was born at Norwich about the year 1590. As an eastern counties man (to one of whose plays, *Titus Andronicus*, the Norfolk and Suffolk boildown owes a lasting poetic commemoration) he naturally received his education at Cambridge, where he took his B.A. from St John's College in 1578, proceeding M.A. in 1583 from Clare Hall, where it is possible that he had expectations of a fellowship. In 1588 he was incorporated at Oxford, so that on some of his title pages he styles himself "utramque Academicum in Artibus Magister," and Nash humorously refers to him as a "utramque Academicum Robertus Greene." Between the years 1578 and 1588 he had travelled abroad, according to his own account very extensively, visiting France, Germany, Poland, and Denmark, and learning at first hand to "hate the pride of Italie" and to know the taste of that poet's fruit, "Spanish misadventures." Whether on his return he took holy orders, the evidence on the subject is insufficient to determine, according to the title page of a pamphlet published by him in 1586 he was then a "student in physicks." Already, however, after taking his M.A. degree, he had according to his own account begun his London life, and engaged in pursuits more congenial to his tastes. He became "an author of plays and a penner of love-pamphlets, so that I some grew famous in that quality, that who for that trade grows so ordinary about London as Robin Greene?" He rapidly sank into the worst debaucheries of the town, though not without being inspired by a passing impulse towards a better life, and decided in consequence by his associates as a "Puritan and Preacher." His marriage, which soon after this took place, failed to steady him, if Francesco, in Greene's pamphlet *Never too late*, as intended for the author himself, it had been a runaway match, but the fiction and the autobiographical sketch in the *Repentance* agree in their account of the unfaithfulness which followed on the part of the husband. He lived with his wife for a while; "but forasmuch as she would persuade me from my wilfull wicked-

nes, after I had a child by her, I cast her off, having spent up the marriage money which I obtained by her. Then left I him at six or seven, who went into Lancashire, and I to London," where his reputation as a playwright and writer of pamphlets "of love and vaine fantasies" continued to increase, and where his life was a feverish alternation of labour and debauchery. He tells us how in the end he was friendless "except it were in a few alehouses," where he was respected on account of the score he had run up. When the end came he was a dependant on the charity of the poor and the pitying love of the unfortunate Henri Minger has drawn no picture more sickening and more pitiful than the story of Greene's death, as told by his Puritan adversary, Gabriel Harvey—a vicious though not an unrepentant narrator. (Greene had stung his vanity by an allusion to his paternal origin in the prose tract of *A Quip for an Upstart Courtier*.) After a banquet where the chief guest had been the dramatist Nash,—an old associate and perhaps a college friend of Greene's, any great intimacy with whom, however, he seems to have been anxious to disclaim,—Greene had fallen sick "of a surfeit of pickle herringe and Flemish wine." At the house of a poor shoemaker near Dowgate, deserted by all except his compassionate hosts and two women,—one of them the mother of his illegitimate son, Fortunatus Greene—he died, September 2, 1592. Shortly before his death, he wrote under a bond for ten pounds which he had given to the good shoemaker, the following words addressed to his long forsaken wife:—"Doll, I charge thee, by the lone of our youth and by my soules rest, that thou wilt see this man paid, for if hee and his wife had not succoured me, I had died in the streets.—ROMNEY GREENE"

Shortly after Greene's death the dramatist Henry Chettle published a pamphlet from the hand of the unhappy man, entitled *Greene's Groats-worth of Wit bought with a Million of Repentance*. This ill-starred production may almost be said to have done more to excite the resentment of posterity against Greene's name than all the avowal for which he so unctuously professed, his (doubtless sincere) repentance. For in it he chose to point the fact of his own conversion by recounting those of his *quondam* acquaintance to go and do likewise. Of these three Marlowe was one—to whom and to whose creation of "that Atheist Tamburlaine" (perhaps to both author and hero under the name of the latter) he had repeatedly alluded on referred in previous pamphlets. The second was Peele, the third probably Nash. But the passage addressed to Peele contained a transparent allusion to a fourth dramatist, who was an actor likewise, and of whom Greene accordingly thought himself entitled to speak with insolent arrogance as of "an upstart owbe beautified with our feathers, that with his *Tygs as hant wrapt in a playes hyle* supposes hee is as well able to bombast out a blanke-verse as the best of you, and being an absolute Iohannes-factotum, is in his owne conceyt the onely shako scene in a countrey." The phrase italicized parodies a passage occurring in *The True Tragicall of Richardus, Duke of Yorke*, &c., and retained in Part III of *Henry VI*. If Greene (as many eminent critics have thought) had a hand in *The True Tragedie*, he must here have intended a charge of plagiarism against Shakespeare. But it seems more probable that, while (as Mr. R. Simpson suggested) the upstart crow beautified with the feathers of the three dramatists is a sneering description of the actor who declaimed their verse, the animals of the whole attack (as Dr. Ingely explains it) is revealed in its concluding phrases. "This 'shako-scene,' i.e., this actor, had ventured to intrude upon the domain of the regular staff of play-wrights—then monopoly was in danger!"

Altogether, not less than thirty-five prose tracts are as-

cribed to Greene's prolific pen. To these, which are by no means all of a personal or even controversial character, he owed in his lifetime a great part of his celebrity. Nearly all of them are interspersed with verses, in their themes they range from the "miscellaneous" wonders of the heavens to the familiar but "pernitious sleights" of the sharpshooters of London. But the most widely attractive of his prose publications were no doubt those in which he more especially refers under the designation of "love-pamphlets," and which, as he tells us, brought upon him the outcry of Puritan censors. In these popular productions he appears as a distinctly as a follower of the fashionable euphuistic style, indeed two of them are by their titles announced as a kind of sequel to the mother romance. But though Greene's style shows the same balanced oscillation to and fro, and his diction the same elaborate ornateness, as those of Lyly, he contrives to interest by the matter as well as to attract attention by the manner of his narratives. It is known that on his *Pandosto, the Triumph of Time* (1588) Shakespeare founded his *A Winter's Tale*; in fact, the novel contains the entire plot of the comedy, though some of the subordinate characters in the latter (including the immortal Autolyca) were added by Shakespeare.

In Greene's *Never too late*, announced in its author's modest vanity of the epithet of "Powder of Experience" sent to all youthful gentlemen "for their benefit," the hero of the *Palmers* story is in all probability intended for Greene himself, and this episodic narrative has a vivacity and truthfulness of manner which savour of an 18th century novel rather than of an Elizabethan tale concerning the days of "Palmerin, King of Great Britaine." The experiences of the Roberto of *Greene's Groats-worth of Wit* are even more palpably the experiences of the author himself, though they are possibly overdrawn—for a born rhetorician exaggerates everything, even his own sins. Much that might be enlarged upon in Greene's manner as a writer of prose fiction shows how already in the Elizabethan age there was a possibility of the English novel antcipating what proved the slow course of its actual development.

For us, however, Greene's name lives chiefly if not solely as that of a dramatist. Only four plays remain to us of which he was indisputably the sole author. The earliest of these seems to be *The History of Orlando Furioso*, one of the *Twelve Peeres of France*—which has (on unsatisfactory evidence) been dated as before 1586, and is known to have been acted on February 21, 1592. It is a fine dramatic adaptation of Ariosto (who in one passage is textually quoted), and contains a large variety of characters and a superabundance of action. Fairly lucid in arrangement and fluent in style, it lacks in the treatment of its main situation—the madness of Orlando—the tragic power to which in truth its author was a stranger. Greene's *Orlando* has been described as "a stepping stone to *Lea* and *Hamlet*," but its priority to Kyd's *Spanish Tragedy* (to which the author of this observation likewise refers) is not proved. Very few dramatists between Sophocles and Shakespeare have succeeded in subordinating the grotesque effect of madness to the tragic, and Greene (the close of whose play is tameness itself) is not among the number.

Of the *Comical History of Alphonsus, King of Arragon*, Henslowe's *Diary* contains no trace. But it can hardly have been first acted long after the production of Marlowe's *Tamburlaine*, which had been brought on the stage at least three years before. For this play—which is oddly enough called "comical," though it contains not a single comic character, and is rarely unintentionally humorous in the effect of some of its passages—was manifestly written in emulation of Marlowe's tragedy. While Greene cannot have thought himself capable of surpassing Marlowe as a

lagic poet, he very probably wished to outdo him in "business," and to equal him in the last which, since there has been an English theatre, has been seen to bring down at least part of the house. *Alphonsus* is accordingly not less sensational than *Tamburlaine*, and supplied its share of quotations to ancient Pistol. It is a *husten* proper, a dramatized chronicle or narrative of warlike events, and a very effective one of its kind. Its fame could never equal that of Marlowe's tragedy, but its composition showed that Greene could seek to rival the most popular drama of the day, without falling very far short of his model.

In the *Honourable History of Friar Bacon and Friar Bungay* (not known to have been acted before February 1592, but very possibly written by 1588) Greene once more attempted to emulate Marlowe, but on this occasion, while producing something very different from the play with which he placed his own in competition, he succeeded in producing a masterpiece of his own. Marlowe's *Doctor Faustus*, which there is every reason to believe suggested the composition of Greene's comedy, is a work which, even in the form in which it has come down to us, reveals the mighty tragic genius of its author, and it was fortunate for Greene's fame that he resolved on an altogether distinct treatment of a cognate theme. Intertwining with the popular tale of Friar Bacon and his wondrous doings a charming idyll (so far as we know, of his own invention), the story of Prince Edward (I?')s love for the Fair Maid of Bravingfield, he produced a comedy brimful of amusing action and genial fun, and at the same time containing dramatic love-story of unsurpassed freshness and brightness. *Friar Bacon* remains a dramatic picture of English life with which *The Merry Wives* alone can vie, and not even the ultra classicism in the similes of its diction can destroy the naturalness which constitutes its perennial charm.

In *The Scottish History of James IV* (not printed till 1898, acted by 1592) Greene seems to have reached the climax of his dramatic powers. The "historical" character of this play is pure pretence, so that one wonders how a Tudor dramatist could have dared to invent a fictitious name and unreal experiences (of a painful kind) for King Henry VII's daughter. Its theme is the illicit passion of King James for the chaste lady *Ida*, to obtain whose hand he endeavours, at the suggestion of a villain called Ateukin, to make away with his own wife. She escapes in doublet and hose, attended by her faithful dwarf, but on her father's making way upon her husband to avenge her wrongs, she effects a reconciliation between them. Not only is this well-constructed story effectively worked out, but the characters act vigorously drawn, and in Ateukin there is a touch of lago. The fooling by Slipper, the clown of the piece, is unexceptionable, and last even so the play should hang heavy on the audience, its action is carried off by a "pleasant comedy"—i.e., a pseudo and some dances between the acts—"presented by Oberon, King of Fayries"—the Oberon of *A Midsummer Night's Dream* (probably later in date than Greene's play).

It is hard to have to abandon the belief that *George a-Greene the Pinner of Wakefield* (printed 1599), a delightful picture of English life fully worthy of the author of *Friar Bungay*, has been rightly attributed to him. Of the comedy of *Fair Em*, which resembles *Friar Bacon* in more than one point, it is most improbable that Greene was the author. The disputed question as to his supposed share in the plays on which the Second and Third Parts of *Henry VI* are founded has been already referred to. He was certainly joint author with Thomas Lodge of the curious drama called *A Looking Glass for London and England* (printed 1594)—a dramatic apologue conveying to the living generation of Englishmen the warning of Nineveh's corruption and prophesied doom. The lesson was fre-

quently repeated in the streets of London by the "Nine wits' morris" of the puppets, but these are both fine and wealth of language in Greene and Lodge's output. The comic element is not absent being supplied in abundance by Adam, the clown of the piece, who belongs, to the family of Slipper and of *Friar Bacon's* servant, Mice.

Greene's dramatic genius has nothing in it of the intensity of Marlowe's tragic muse, nor perhaps are there any passages in his poetry equalling certain of Peelo's when at his best. On the other hand, of none of Shakespeare's predecessors or contemporaries can it be said, as of Greene, that his dramatic poetry is occasionally animated with the breezy freshness which no artifice can simulate, but which nothing but obtuseness can mistake. He can construct readily and with facility, though of course belonging to a period of our dramatic literature when the art of construction was still in its infancy. He has created no character of commanding power—unless Ateukin be accepted, but his personages are living men and women, and marked out from one another with a vigorous but far from rude hand. His comic humour is undonable, and he writes a spurt of true farcical fun with a capacity for light and graceful dialogue. His diction is overloaded with classical ornament, but even thus he frequently employs with pleasing aptness His versification is easy and fluent, and its cadence is at times singularly sweet. He creates his best effects, like a true artist, by the simplest means, and he is indubitably one of the most gifted and one of the most pleasing among our early dramatic authors.

The best account of Greene and his writings (including a list of all his prose works) is that by the late Mr. Dyce, prefixed to his edition of *The Dramatic and Poetical Works of Robert Greene*, 1 vol., 1861, the 2nd vol. edition was published in 1881. It contains copious extracts from *Pendennis*, and from other prose writings of Greene. *Greene's Great work of 1570* is printed in part of Dr. Ingley's *Shakespeare's Allusion Books* (*New Shakespeare Society's Publications*, 1874). Dr. Ingley's general introduction, and a supplement by the late Mr. Richard Symonds, as well as the observations in Mr. Symonds's *School of Shakespeare*, will be of great value to readers of Greene. W. B. Stein's *Robert Greene's Leben und Schaffen* (Leipzig, 1874) is an essay full of useful research, and Prof. J. M. Brown of Christchurch, New Zealand, has contributed a spirited, but at the same time judicious, criticism of Greene to the *New Zealand Magazine* for April 1877. A Russian monograph on him by N. I. Stokorshko (*Moscow*, 1878) is described as perhaps the fullest hitherto published. *Friar Bacon and Friar Bungay* has been edited, together with Marlowe's *Doctor Faustus*, for the Oxford Olenand Press (1878). (A. W. W.)

GREENFINCH (German *Grünfink*) or GREEN LINNET, as it is very often called, a common European bird, the *Fringilla chloris* of Linnaeus, ranked by many systematists with one section of Hawfinches, *Coccothraustes*, but apparently more nearly allied to the other section *Leoprythina* (cf. Finch, vol. ix p. 192), and perhaps justly deemed the type of a distinct genus, to which the name *Chon* or *Ligurina* has been applied. The cock, in its plumage of green and gold, is one of the most finely coloured of our common birds, but he is rather heavily built, and his song is hardly commended. The hen is much less brightly tinted. Throughout Britain, as a rule, this species is one of the most plentiful birds, and is found at all seasons of the year. It pervades almost the whole of Europe, and in Asia reaches the river Ob. It visits Palestine, but is unknown in Egypt. It is, however, abundant in Mauritania, whence specimens are so brightly coloured that they have been deemed to form a distinct species, the *Ligurina aeneiventris* of Mr. Osborn, but this view is now generally abandoned. In the north-east of Asia and its adjacent islands occur two allied species—the *Fringilla sinica* of Linnaeus, and the *F. lanceolata* of Temminck. No species of Greenfinch is found in America. (A. W.)

GREENHEART, one of the most valuable of timbers, is the produce of *Nectandrus Rododendron* and *Lauraceae*, a tree

which grows to a height of 70 feet, native of Guam, where, indeed, it exists in great abundance. The Indian name of the tree is *Sapi* or *Bibun*, and from its bark and fruits is obtained the valuable principle *Biburine* (see *BIBURINE*). Greenheart wood is of a dark green colour, sap wood and heart wood being so much alike that they can with difficulty be distinguished from each other. The heart wood is one of the most durable of all timbers, and its value is greatly enhanced by the fact that it is proof against the ravages of many marine borers which rapidly destroy pine and other subarctic structures of most other kinds of wood available for such purposes. In the Kelvingrove Museum, Glasgow, there are two pieces of planking from a wreck submerged during eighteen years on the west coast of Scotland. The one specimen—greenheart—is merely slightly pitted on the surface, the body of the wood being perfectly sound and unaltered, while the other—oak—is almost entirely eaten away. Greenheart, tested either by transverse or by tensile strain, is one of the strongest of all woods, and it is also exceedingly dense, its specific gravity being about 1150. It is one of the few woods included in the first class of Lloyd's Register for shipbuilding purposes, and it is extensively used for keelsons, beams, engine benches, and planking, &c., as well as in the general engineering arts, but its excessive weight unfits it for many purposes for which its other properties would render it eminently suitable.

GREENLAND, or **GRONLAND**, is the name applied to a large continental island, the greater portion of which lies within the Arctic Circle, and all of which is arctic in character (see vol. i, Plate X). It is entirely unconnected with any portion of Europe or America, though in the extreme north only separated from the latter by the narrow strait which lies between it and the outlying portion of America known as Ginnell Land. From Europe it is divided by the North and Greenland Seas—the Faroe Isles, Jan Mayen Island, Iceland, and part of Shetland being the only lands between it and Norway. Denmark Strait is the sea between it and Iceland, and it is more than probable that Spitzbergen is the only great group of islands lying to the east of its northern portion. On the west, Davis Strait and Baffin's Bay separate it from the opposite shore. The latter sea narrows to the north into the gulf generally known as Smith Sound, though, in reality, Kane Sea, Kennedy Channel, Hall Basin, and Robeson Channel are the names which have been successively applied in the progress of exploration to the northern continuations of the sound so named more than two hundred years ago by William Baffin. The exact northern termination of Greenland is not known, the country never having been doubled on the north, but we know enough from the explorations of Matham, Beaumont, and other officers of Narve's expedition, to lead to the conclusion that the ice encumbered Polar Ocean circles around the headlands of the broken country which forms its supposed limits in about 83° N lat.

From Cape Farewell, or Kangersuak,—an island lying about 18 miles from Pamiagluk, the most southern Danish post on the west,—to Cape Britanna, is about 1380 miles, and the greatest breadth of Greenland is about 77° 30' N lat.—680 miles from the one coast to the other. The shore-line is fully 3100 miles long, but so little is the country known with accuracy, and so broken is it by fjords and coast lying islands, that any accurate estimate of its area is impossible. Thus Dr. Rink, who has been connected with the government in various capacities for upwards of thirty years, estimates its area at 512,000 square miles. This estimate allows 192,000 square miles for what has been called the outskirts—or islands uncovered by ice—with their fjords, and 320,000 for the interior, believed to be almost entirely covered by a glacier ice cap.

On the east coast, Cape Bismarck, in 76° 47' N lat., marks

the limits of exploration, though as early as 1670 Lambert is said to have sighted land several degrees further north. From Cape Bismarck south to Cape Farewell (59° 35' N lat.) the coast is very imperfectly known, whole stretches being entirely uncharted, even in the rudest fashion. This arises from the Spitzbergen ice stream continually pouring down that shore, rendering it possible to approach within sight of it only on rare occasions, and to land still more rarely. Yet, from the explorations of Hall and Lindenow in early times, and those in this century by Scoresby, Graah, the German expedition, and Malmgren (1879), we know several general features. These are—high, beetling cliffs, great glaciers creeping down to the sea, and deep inlets, like Scoresby Sound and Franz Josef Fjord, penetrating the land for distances which cannot as yet be definitely stated. A number of islands also are dotted over the chert here, but there are few "ice fjords," the slope of the inland ice being evidently chiefly towards the west coast. The west coast is of much the same character,—only, on this side, the fjords with which it is intersected have been nearly all followed to their heads. Many of them stretch several miles into the interior, and the greater number are ended by glacier prolongations of the "inland ice," which discharge icebergs, these are known as "ice fjords." On Greenland fjords, like those in Norway, British Columbia, and other countries with a western exposure, bear every mark of having been at one time the beds of glaciers, when the climate and physical geography of the country were different from what they are at present. The country cannot be said to be mountainous, yet heights of from 3000 to 4000 feet are common, and the aspect which the coast presents is that of high cliffs,—black when steep, white where the snow can lie, snow for eight or nine months in the year on even the lower lands, icebergs and broken floe ice floating off the coast, an "ice foot" attached to the shore early in the spring, and glaciers pouring down through the valleys between the cliffs and fields. There are one or two still higher points, such as Petermann's Peak—near the shores of Franz Josef Fjord on the east coast (11,000 feet), Payer's Peak, Salkestauppen, and the familiar Sanderson's Hope. With the exception of Disco, there are no large islands, but the bays, fjords, straits, and peninsulas of this extremely broken coast are so numerous that it is needless mentioning them by name.

The Inter-ice covering—The Danes divide Greenland into two physical divisions—the "outskirts" and the "inland ice." The first comprises the coast-lying land, the latter the interior. If we ascend any considerable eminence on the west coast, and look eastward, we do not find mountains and valleys as in most other countries, but only one huge, seemingly endless, expanse of glacier ice gradually rising towards the east, until the view is bounded by a white horizon. If we cross the coast-lying land, which varies in breadth from a few miles to twenty, or in a few cases much more, we come to this "inland ice," generally in the form of a glacier offshoot of it which has crept down into a fjord, or is making its way to the sea in one of the mossy valleys lying between two high cliffs, noisy with mollemoles or with the water scream of diatoms, which at various sheltered places have colonies in these "skærvelfelde." In the former case the glacier usually presents a steep wall facing the sea, from which great fragments of ice are continually breaking off, or the icebergs being detached by the force of the sea, then it is "somewhat weak"—the "great ice wall"—of the Ekkin. In the latter case, it presents a slope on which the explorer

¹ *Journal of a Voyage to the Northern Whale Fishery* (1823)

² *Reise til Ostlysten af Grønland* (1882), taken by G. Gordon Macdonald, 1857

³ *København, Die meiste deutsche Nordpolarfahrt* (1870-75)

can climb, and ascend into the interior over the inland ice, of which it is a prolongation. A little way seaward, the covering is found to be hard glacier ice, rising by a gentle slope,—covered in the winter and spring with a thick coating of snow, which partially melts during the summer, forming considerable lakelets on the surface of the ice, or comes over it in the shape of streams that thunder down the deep crevasses which divide it here and there as in ordinary glaciers. No sign of living thing is seen on it, save patches here and there of a low order of plants identical with or allied to the "red snow" (*Amylonema Nordenskiöldii*), *Protococcus vulgaris*, *P. nivalis*, and *Strydomma gracilis*, no mollusks of any description, showing that the ice could not have impinged on land in its travels, and no sign of the ice having come in contact with any other physical influence save that of the atmosphere, unless the presence here and there in hollows of the minute powder-like mineral "kyokomuts" is to be considered an exception. The few explorers who have even attempted to penetrate this terrible waste all give the same account. Travel eastward, and nothing but ice—rough, crevasse-torn, white, earthless, mountainous, lifeless—is seen, until, in the far distance, the view is bounded by a dim, misty horizon of ice, which, at a distance of about 30 miles inland, rises to a height of 2000 feet above the sea. North is ice, south is ice, and behind are seen the "outsides" of ice but no land. The only exception to this general statement is to be found in the fact that here and there the ice has laked in and surrounded, but not yet covered, bits of high land near the coast, which stand out black amid the surrounding icy whiteness. Such an island in the ice is known to the Greenlanders as a "nunatak." A noted one has long been known to exist some 50 miles east of the westward edge of the inland ice north of Frederikshaab. It was long supposed to be merely the east coast mountains, the country being narrow at this point, but the explorations of Lient Jensen, R.D.N., in July and August 1878, prove it to be a peak 5000 feet high,—i.e., about 3000 feet above the surrounding ice,—entirely isolated. On the other side of this mountain ridge the glacier field was observed stretching without interruption as far as the eye could see, the plateau apparently rising higher and higher to the east,¹ which may account for the fact that the German explorers did not notice the inland ice in their explorations of Franz Josef Fjord. The high peak only proves that, though in the course of ages the winter snow, unmelted by the summer heats, has got compressed into the glacier sheet which has covered the interior, and is partially discharging its surplus in the form of icebergs on the coast, it has not yet accumulated to such depths as to overwhelm these elevated places. It may, however, do so in time, for, though it is clear that at one time the climate of Greenland was very different from what it is now, it is equally evident that at no very distant date the ice overspread much of the now uncovered outskirts. The so-called "glaciers" which reach the sea are long or short, broad or narrow, according to the character of the valley through which they creep seaward. Thus a coast "glacier," so called, may be 40 miles broad, like the Giant Glacier of Humboldt, or only a few yards, like most of the others in Greenland. When the glacier reaches the sea it plunges along the bottom, until, by the force of the water, its end is buoyed up and finally broken off in the shape of an iceberg, which is carried by the winds and currents out to

sea to be in time again melted and absorbed into the ocean whence it originally sprang. If, on the contrary, the sea is shallow, the glacier will extend for a considerable distance, as in the case of the Ishland a little north of the fishing-station of Aviaut (62° 32' N lat.), which is a low sandy beach projecting about 8 miles in front of the inland ice, and forming a breakwater against the force of the waves. From under the Arctic glacier points, as in the Alpine ones, a muddy stream, which salts up some of the fjords, and forms deposits identical with the laminated glacial clays of Britain. Such, in brief, is the inland ice of Greenland, which has been known since the days of Fabricius,² but has only been recently generally recognized, and even yet is imperfectly understood in its all-important bearings on the study of ancient glacial remains.

Geology.—So far as made out, the structure of explored Greenland is as follows:

(1) *Lava culian quarts* forms the greatest mass of the exposed rocks of the country base of ice. They are found on both sides of Smith Sound, ranging to heights of 2000 feet, and undating the Miocene and the various rocks of Duco Island, Noulso Peninsula, and the Oolites of Pandulum Island in East Greenland. It is possible that some of these rocks are also of Huronian age, but it is doubtful whether the rocks so designated by the geologists of the "Albat" and "Ducoway" expeditions are really the rocks of Huronian in Canada, or vice a continuous portion of the fundamental or oldest gneiss of the north west of Scotland and the Western Isles.

(2) *Silurian*.—Upper Silurian, having a strong relation to the West group of Britain, but with a few peculiarities, as in the Silurian, with a succession much the same as in British North America, are found on the shores of Smith Sound, but not as yet so far south as the Danish possessions.

(3) *Dumoureaux* rocks are believed to occur in Igloolik and Tunnuk diobik fjords, in S.W. Greenland, but as they are unfossiliferous systems, rapidly disintegrating, this cannot be known. It is, however, likely that this formation occurs in Greenland, for in Dana Bay, Cape Falden found a species of *Spirifer*, and an *Orthis maculosa* or *costata*, though it is possible that these fossils indicate the "Dana stage" (Elen) of the Lower Cambrian time. But a few *Dumoureaux* forms have also been recorded from the locality Achuleg, which tends to confirm belief in the existence of a sporadic *Dumoureaux* formation in Greenland.

(4) *Carboniferous*.—In certain blocks of sandstone, found on the Disco shore of the Wuygits, have been detected a *Spirifer* and a species of either *Pecepia* or *Glenchiera*, pelecypods of this age, and probably much of the extreme northern coast of Grinnell Land, and therefore, in all likelihood, the opposite Greenland shore, contains a fully developed Carboniferous Limestone fauna, identical with that so widely distributed over the North American continent, and referable also to British and Spitzbergen species. Of the Coal Measures above these, if they occur, we know nothing at present. Capt. Feilden's thesis as suggestive of the same formation does not meet with this formation on the northern shores of Greenland, yet it was observed that a continuation of the direction of the known strike of the limestones of Feilden's peninsula, carried on to the polar sea, passes through the neighbourhood of Spitzbergen, where the formation occurs, and contains certain species identical with those of the Grinnell Land rocks of this horizon. The fossils in the rocks, according to Sir E. de la Beche, North American and Canadian, though many of the species are British. The corals are few in number, but the *Mollusconia* (*Polygona*) are more numerous in species and individuals. No Secondary rocks have been discovered in the extreme northern parts of West Greenland, but they are present on the east and west coasts in more southerly latitudes than Smith Sound.

(5) *Jurassic*.—These do not occur on the west coast, but on the east coast the German expedition discovered small and scattered on Kuhn Island, resembling those of the Russian Jurassics, characterized by the presence of the genus *Aucella*, an ammonite (*Pezophaedusa* *Pagoda*), *A. stylata*, *Belmontella*, *Pezodactylus*, *S. solenaria*, *S. alveticus*, and a *Cypripes* near to *C. pyrenaea*. On the south coast of the same island are coarse-grained, brownish micaceous, and light-colored calcareous sandstone and marls, containing fossils, which render it probable that they are of the same age.

debtors, on paying freight for them at the rate of 2½d per 10 lb, or 1s 4d per cubic foot. The prices to be paid for European articles are fixed every year, the prices current in Danish and Eskimo being printed and distributed by the Government. According to a calculation, founded on the average of the last few years, about 23 per cent of the value in the European market is paid for the products in Greenland. Out of the payment six-sixths are given to the seller, and one-sixth devoted to the Greenlanders' public fund, spent in "public works," in charity, and on other unforeseen contingencies. The object of the monopoly is solely for the good of the Greenlanders,—to prevent spirits being sold to them, and the vice, disease, and misery, which usually attend the collision between civilization of the trader's type and barbarism, being introduced into the primitive arctic community. The inspectors are, in addition to being paid superintendents, magistrates, but serious crime is practically unknown, while the cases of theft which have occurred within a decade are so few that they are held in recollection as historical events. The "vices of civilization" are few, and its diseases unknown. The Danish officials are mostly men of considerable intelligence, and all of good character, though their pay is small. The inspector receives £338 and a residence, the average salaries of the 11 "colombesteyere" are £250, of the 18 clerks—"assistants" or "volunteers"—£106, besides residence, fuel, and attendance. In addition there are about 163 "uliggegne," seamen, mechanics, &c., each a stone, each entitled by a short tenure, in the case of the outpost traders, a percentage on their trade. Though the officials are all-powerful, yet, owing to the exactions of Dr. Rank, local councils or "parasisset" were organized in 1857 in every district. To those parish parliaments delegates are sent from every station,—showed men, wise in council, and well acquainted with the wants of the Greenlanders. These "parasissets"—elected at the rate of about one representative to 120 votes—wear a cap with a badge (a bear rampant), and the European members of the council in distributing the surplus profits apportioned to each district, and generally in advising as to the welfare of that part of Greenland under their partial control. In 1873 there was deposited, in a savings bank established in Greenland, £200 as contributions for the support of illegitimate children, £190, 10s, sums gained by inheritance or by other unforeseen circumstances, £791, savings from wages, chiefly those of the Europeans, and £121, savings of the Eskimo, or half-bloods. But thrift is the most prominent feature in the Eskimo character. The "municipal council" has the disposal of 20 per cent of the annual profits made on produce purchased within the confines of each district. It holds two sessions every year, and the discussions are entirely in the Eskimo language. In addition to their functions as guardians of the poor, the parish M.P.'s have to investigate crimes and punish misdemeanors, settle litigations and divide inheritances. They can impose fines for small offences not worth sending before the inspector, and, in cases of high misdemeanour, have the power of inflicting corporal punishment. During the first ten or twelve years the following causes were submitted to trial—one single case of having in possession occasioned the death of a person, and another of openly threatening, five or six instances of grosser theft or cheating, and as many of concealment of birth and crimes relating to matrimony, every year a few petty thefts, and instances of making use of the tools of others without permission, or of like disorders, and several trifling litigations.

Trade.—The trade of Greenland is entirely confined to that part of the coast colonized by the Danes,—the rude natives of South Sound and the east coast contributing nothing to the world's riches. Neither do the civilized people of any other nation trade on the coast, the English "Greenland seal and whale fishery" being a mis-

nomer, for the "fisheries" are pursued on the west coast of Davis Strait and Baffin's Bay, and in the sea between Jan Mayen and Spitzbergen, and occasionally within sight of the east coast of Greenland. Taking the Greenland trade as confined to the coast of the island, according to the calculations of Lund, that the earnings of the 1877 families of Eskimo under the Danish crown are on an average £15,016 per annum, giving each family an average annual income of £48 from the produce of the hunt sold to the royal officials. Thus the Eskimo are in a wide measure supplied with the necessities of life. During the twenty years 1853-72, including cyclones, the average annual capture consisted of 118,661 tons of oil, 45,459 seal skins, 14,356 walrus, 3,338 B row seals, down, 6900 lb walrus, 2400 B whale bone, 550 B walrus ivory, 87 B walrus ivory, 2377 tundra lichen. During the period 1870-74 the mean annual value of the products received from Greenland was £457,000, that of the wages sent thence, £253,614, and the mean expenditure on the ships and crews, £8897. Not including the royalty paid by the company which exports the cyclone (from 1854 to 1874 equal to £68,921), the average profit of the Greenland trade was, for the 21 years between 1853 and 1874, about £8600 yearly. The capital sunk in the "royal trade" is estimated at £64,126, and, taking the whole amount of net revenues from the present trade during the period between 1870 and 1875, the interest on the capital as well as the income from the cyclone royalty being amortized the present "dividend" of the Kongelige Grønlandske Handel consists of £100,000 has been earned.

Trading Districts and Census.—A Danish "colony" in Greenland is not at the best of times a cheerful place, though, in the long days of summer, some of those in the fjords of South Greenland are comparatively pleasant. The houses are almost invariably built of wood, pitched over, and built more or less on a hill for a nice view. In addition to the three or four Danish houses—the usual number at the chief settlement—there are from 20 to 30 to 300 or 400 Eskimo at the place. They usually live in huts built of turf and stone, each entered by a short tunnel, which in most respects are an improvement over the primitive dwellings of the natives (see below). In South Greenland there are, even taking debtors, 14 or 15 follow. *Godthaab* has in 1870 2570 inhabitants, and 8 trading stations. Of the inhabitants, 1050 belonged in 1872 to the Moravian mission settlements, which do not extend much further north, the chief clergy being married, and the remainder, in the town with him and the "Herrnhuters" something of the *adieu theologum* exists. In this district also are the ruins of the old Norse settlements of Red Erik, his contemporaries, and his successors. *Frederikshavn* has 16 trading stations, which collect about 68 tons of oil and 1000 seal skins annually. The population in 1870 was 821, at Ivigtut, in this district, are the cyclone mine, *Godthaab* has 999 people, 6 stations, and a trade return of 74 tons of oil and 1000 seal skins annually. It is the most southern station for entry down, and formerly also for tundra skins. Coal here was also once caught here in great abundance, but this business is now almost abandoned. *Godthaab* "colony" is the chief settlement in the western part of Greenland. Besides the usual trade officials, one or two Danish missionaries who manage the seminary, and two or three Moravian missionaries (at Ny Hermitage), the royal inspector of South Greenland, and the physician for the northern part of the island, are the place. In addition to the seminary, *Godthaab* has a church, of other imposing appearance for Greenland, but too large for the community, and built of brick, a material very little suited to the country. The houses of the natives, almost all with sloping roofs of boards, look very pretty, but at Ny Hermitage they often are of appearance. The latter station has two store buildings, containing accommodation for the missionaries, schoolroom, and church or "meeting hall" as it is called. At *Islandslet* is a small station, where the natives, who the community is within the last thirty years devoted to one-half, and, owing chiefly to the misanthropic asceticism denuded from their flock by these unwelcome men and women, is perhaps the most destitute of material comfort of any in Greenland. There is also a small Norse ruins, part of the reign having been the Victor Bygd of the Icelanders, just as that further south was then Oster Bygd. *Sukleppang* is one of the loftiest and most picturesque stations. It yields about 92 tons of oil and 1000 seal skins, also some cod fish, a few reindeer, and most of the land down of the country. It has six trading posts and 765 people. *Ilulissat* has four trading posts, and now yields about 60 tons of oil and 400 seal skins, besides whale-bone and cod fish. There is also a station at *Ilulissat*. In 67° 40' N lat. Narsutok or North Strom fjord forms the boundary between South and North Greenland, the settlements which follow are therefore in the latter inspection. *Aqarsimide* is a station of 1000 people, the place of the Moravian settlement, 1 tons of oil and 8400 seal skins collected annually by six stations. In 1870 the population was 1008, the greater number living at the chief settlement of the same name. *Christianshaab* has four trading posts, which collect from 100 to 150 tons of oil and 1700 seal skins. *Christianshaab* is one of the pleasantest dis-

times in North Greenland, the valley on the opposite side of the harbour from the "colony" abounding with crowberries and bilberries, and bright in July with the blue and yellow arctic flowers. Ulukavru is the chief port, and derives its support from the seals killed among the numerous coves of icebergs pointed out by the natives. In the fjord of Ulukavru is the bay of Ulukavru. Many of the bergs ground here until they are lifted by spring tides and carried by the wind out into Baffin's Bay. *Sukobak* has eight stations, collecting 144 tons of oil and 500 seal skins in 1864. *Godhavn*, on Disco Island, was at one time a sort of the whole trade, in 1798 no less than 30 whaling livers being caught there, but this industry has now entirely ceased, the last whale caught by the Government officials being in 1861. Its chief importance is in the first ship Godhavn (or Lark) is the seat of the Government of North Greenland, and the place at which exploring and whaling vessels often call. Its trade is insignificant, the district returning on an average only about 30 tons of oil and 400 seal skins, the settlement has for many years been actually a loss to the Government. There are in the district 216 people, who are perhaps the least industrious and self-reliant of all the Greenlanders. *Resend* has five stations, returning 116 tons of oil and 860 seal skins, collected by 447 people. *Umanak* is one of the most profitable districts—the "colony" with its six outposts returning to the "loyal trade" about 180 tons of oil and 8500 seal skins, collected from 798 people. *Qaanaaq*, in the northern district, its limits being those of the natives belonging to the Danish settlements. It is very profitable,—its average return being 145 tons of oil and 6500 seal skins, besides eleven down and seal skins, with furs and a considerable quantity of sundries. In 1870 there were 703 people in the district, the chief of the outposts being Puvua ("the exponent"), and Tasnaak (78° 24' N lat.), the most northern Danish trading post, and the most northern permanent abode of civilized men, for women, for trade here, a Danish wife with him. "To a European female," writes the director of the Royal Greenland House of Trade, "this island seems to be one of the most unattractively placed of residence that can be found." In the year 1864 the Danish mission there was in 1863 appointed teachers, besides several other teachers, as well as seal hunters or hunters. In the society of the loyal trade were 12 outpost traders, 15 head men and 17 "boaters," 14 exporters and smiths, 19 cooper, 12 cook, 12 hunter, 10 painter, 10 musician, and 53 missionaries, 6 officers who were numbered as natives, but 8 of them were more properly Europeans. In the same year the Danes numbered 987, of whom 95 were engaged in the trade, 8 were Danish and 11 Moravian. The missionaries and their families, 110 in all, the rest were women and children. Altogether there were in 1870 9826 people in Danish Greenland (including 9408 natives), and in 1878 9850. The details of the latter census are not published, but they do not in any material manner alter those just given. The inhabitants of the east coast are not believed to exceed 800 if so many, and yearly this number is being lessened by immigration to the Danish settlements on the west coast. The natives of the shores of Smith Sound, north of Melville Bay, number about 200, and it is satisfactory to learn that of late these *Esquimaux* appear to be not decreasing. Their most northern settlement is Erik. From the time of the expedition of Lieut. Hendrick, it appears that Dr Kane was in error in asserting that the Smith Sound natives knew nothing of those to the south of the glaciers of Melville Bay.

History.—Greenland was first landed on about the year 985 by Erik Raudin or Red Erik, a banished Icelandic jail, though some time previously the country had been sighted by Ulf Kinn, another Icelandic. Erik and his house only settled at Danneberg, the present future station of Isortoq, situated on an isthmus between two fjords, believed to be the Erik's and Emma's Fjords of the old saga, who to this day can be traced the walls of about seventeen dwellings, one of which bears evidence of having been Erik's house. Other stations follow, and among these was that of Herjolfs, one of Erik's companions, whose home was probably at Herjolfs Ness, opposite the Moravian settlement of Frederiksdal, where have been found tombs containing the bodies of men, who were interred in coarse heavy cloth, and both pagan and Christian tombs with inscriptions. This Bjart, in his wanderings, discovered the coast of America (Vinland), and among those who were situated here was Leif, who went ashore near what is the town of Tantroum now stands. After this there is said to have been a considerable trade between Norway and America, and between both countries and the Greenland colonies. The latter even penetrated to 73° N lat. as early as 1385, and left a small stone stone recording the event. Christianity was introduced, and Arnold

appointed the first bishop, in 1556, and Greenland, like Iceland, had a republican organization up to the year 1524, when Jakob Hansson, king of Norway, induced the Greenlanders to swear allegiance to him. Henceforth they were Norway in subject, and the queen's name was put on the coins. The cause of the loss of the beginning of their decay and final disappearance as colonies, though the black death, foreign wars, and the attacks of the Eskimo, who about this period built up upon the colonies from the north, had something to do with it. These attacks of these "lost colonies" and their ungainly survivors. The first bishop appointed to Greenland died in 1510, but long before that date those appointed had never reached their seats. The country had also been visited by a hostile fleet (believed to be English), and about the end of the 15th century it would appear that all colonization had ceased. When in 1556 John Davis visited it there was no sign of any people except the Eskimo, among whose hunters were one or two relating to the old Norsemen. For more than 300 years Greenland seems to have been neglected—almost forgotten. It was visited by whalers, chiefly Dutch, but nothing in the form of permanent settlements was established until the year 1721, when the first missionary, Ilmarin, landed. And many hardships and discouragements he presented, and at the present day the memory of the native is as it were and Christians, instead of wild and pagan, as they were when he arrived among them. The colonies of the 18th century were, many of them, converts and other colonies, and the trade was a monopoly in the hands of private individuals. In 1733-34 there was a dreadful epidemic of small pox which destroyed an immense number of the population. In 1771 the trade was to be profitable as a private monopoly, and to prevent it being abandoned the Government took it over. In 1807-11, owing to the war, communication was cut off with Denmark, but since that date the country has been prospering in a gradual fashion, though, if the Government ceased its fostering care, the Eskimo, and with them what trade is carried on, must become extinct.

Of late years, the northern part of the country has been explored by Inuit (1852), Kane (1855), and others (1860-61), Hall (1871-73), and to some extent by Nares (1875-76), whose discovery of the probable northern termination of the country in about 85° N lat. has been already presumed. The country has been explored by the expedition (1822) Cleveland (1823), Grinnell (1829-30), the German expedition (1860-70), and Monnet (1879), while the interior has been penetrated by a shoal of the Danes, Americans, English, and Swedes whose names have been noted above, and by others. In like manner, the scientific history of the country has been investigated by a host of savants from the days of Fabrian to our own, whose names are too numerous to record, though, in the works above quoted, these are given rather directly or indirectly. For further information see the articles *ESKIMO* and *POLAR REGIONS*. (R D)

GREENLEAF, SIMON (1783-1853), American jurist, was born at Newburyport, Massachusetts, December 5, 1783. After studying law in Massachusetts and Maine, he began in 1806 to practise at Starish in the latter State, proceeding finally to Portland in 1818. There, for two years, he became reporter of the supreme court of Maine, and during his twelve years of office published nine volumes of *Reports*. Resigning in 1832, Greenleaf became in 1833 Royce professor, and in 1846 Dane professor of law in Harvard University, where he received the degree of doctor of laws. He retired in 1848 from his active duties, becoming emeritus professor, and after being for some years president of the Massachusetts Bible Society died at Cambridge, Mass., October 6, 1853.

Greenleaf's principal work is *1. Treatise on the Law of Evidence, 1842-28*. He published also *A Full Collection of Cases Overruled, Reversed, or Limited in their Application, taken from American and English Reports*, in 1810, expanded afterwards to 3 volumes, and an *Examination of the Testimony of the Four Evangelists by the Rules of Evidence administered on the Courts of Justice, and the Fruit of Justice*, in 1816. This was republished in England in 1847.

³ This stone, not much bigger than a bone, was until recently in the Copenhagen Museum. It was stolen, however, and the priceless monument is now only represented by a model.

The harbour constituted under this agreement was not finished till 1710, in which year Gloucester was established as a custom house port. In 1721 an Act of Parliament was obtained whereby a duty of 5d Scots was imposed on every Scots part of ale or beer "brought, brought in, brewed, or sold" within the town "for cleaning, deepening, building, and repairing" the harbour and piers. Till the year 1772 the harbour was simply leased to the town by the superior, but in that year and in 1773 the magistrates and town council were tried, and found guilty of the same "for cleaning, deepening, building, and repairing" the harbour and piers. From that date down to the present time the additional mile to the harbour by parliamentary authority have been very numerous. The dock and quay accommodation now amounts to eighty acres. In addition there is in course of construction in immense dock to be named the "James Watt Dock," which is intended to afford accommodation to vessels of the largest tonnage, and to contain them when the water is in the state of the tide. The estimated cost of this dock, with warehouses and sheds, is £250,000. The harbour trustees who now have the management of the docks consist of the town council and nine elective members chosen by the local shipowners and harbour pilots.

The commercial prosperity of Gloucester secured its first great impetus from the Treaty of Union in 1707. The earliest trade seems to have been in herring, a trade which, however, has long been extinct. Trading in tobacco was also carried on at a very early period. It was first brought from the colonies, and then exported to the Continent. The Greenland and whale fishing commenced as far back as 1762, but it never rose to be of any importance, and is now discontinued. The American trade commenced the progress of Gloucester, as the principal trade of the port was then with that country, but after the peace in 1783 it speedily receded, and within the seven following years the shipping trade was reduced in amount to the present small number of vessels in trade with the East and West India, Australia, and the United States and Grenville, Newfoundland and South America have also employed a considerable quantity of shipping. The greatest measure of trade is shown by the following table of the number and tonnage of vessels that entered and cleared from and to foreign ports in various years since 1781 —

	INWARDS				OUTWARDS			
	British		Foreign		British		Foreign	
	No.	Tons	No.	Tons	No.	Tons	No.	Tons
1781	52	6,669	4	530	63	7,297	8	520
1804	165	80,802	25	5,120	155	81,896	20	5,965
1821	188	45,162	11	5,054	188	46,887	9	4,899
1853	271	64,576	44	18,761	198	55,680	45	11,975
1878	428	219,521	178	64,918	419	198,287		

Interesting historical details may be found in *Memoirs of James Watt*, by G. Williamson, 1856. The first volume of *Historical Sketches of the Town and Harbours of Gloucester*, by Dr. Hugh Campbell, appeared in 1879. (J. P. A.)

GREENOUGH, HENRY (1805-1852), an American sculptor, son of a Boston merchant, was born at Boston, September 6, 1805. At the age of sixteen he entered Harvard College, but while there he devoted his principal attention to art, and in the autumn of 1825 he went to Rome, where he enjoyed the advantage of instruction from Thorwaldsen. After a short visit in 1826 to Boston, where he executed busts of John Quincy Adams and other persons of distinction, he returned to Italy and took up his residence at Florence. Here one of his first commissions was from James Fenimore Cooper for a group of Chanting Cheatebs, and the success of this work, joined to the strong recommendation of Cooper, Dana, Everett, and others, led to his being chosen by the Government to execute the colossal statue of Washington for the national capital. It was unveiled in 1843, and as an accurate likeness, conceived in a lofty and truly poetical spirit, it is entitled to high rank among modern works of a similar kind. Shortly afterwards he received a second commission from Government for a colossal group, the "Rensselaer," intended to represent the conflict between the Anglo-Saxon and Indian races. In 1851 he returned to Washington to superintend its erection, and in the autumn of 1852 he was attacked by brain fever, of which he died, 18th December. Among other works of Greenough may be mentioned a bust of Lafayette, the Medora, and the Venus Victus in the gallery of the

Boston Athenæum. Greenough was a man of wide culture, and his occasional productions in prose and verse gave evidence of a capacity to attain the same eminence in literature as in art. See *Memoir of Henry Greenough*, by H. T. Tuckermann, 1853.

GREENSHANK, one of the lugest of the birds commonly known as Sandpipers, the *Totanus glottis* of most ornithological writers. Some exercise of the imagination is however needed to see in the dingy olive coloured legs of this species a justification of the English name by which it goes, and the application of that name, which seems to be due to Pennant, was probably by way of distinguishing it from two allied but perfectly distinct species of *Totanus* (*T. solitarius* and *T. fusca*), having red legs and usually called Hesh-shanks. The Greenshank is a native of the northern parts of the Old World, but in winter it wanders far to the south, and occurs regularly at the Cape of Good Hope, in India, and thence throughout the Indo-Malay Archipelago to Australia. It has also been recorded from North America, but its appearance there must be considered accidental. Almost as bulky as a Woodcock, it is of a much more slender build, and its long legs and neck give it a graceful appearance, which is enhanced by the activity of its actions. Disturbed from the moon or marsh, where it has its nest, it rises swiftly into the air, conspicuous by its white back and rump, and uttering a shrill cry which sends the intruder. It will perch on the topmost bough of a tree, if a tree be near, to watch his proceedings, and the cock exhibits all the astounding gymnastications in which the males of so many other *Lamcolæ* indulge during the breeding season—with certain variations, however, that are peculiarly its own. It breeds in no small numbers in the Hebrides, and parts of the Scottish Highlands from Argyleshire to Sutherland, as well as in the more elevated or more northern districts of Norway, Sweden, and Finland, and probably also from thence to Kamchatka. In North America it is represented by two species, *Totanus empalmatus* and *T. melanocorys*, there called Willets, Tattlers, or Tattlers, which in general habits resemble the Greenshank of the Old World. (A. N.)

GREENWICH, a market town and parliamentary borough in the county of Kent, England, is pleasantly situated on the right bank of the Thames, 6 miles SE of London Bridge by the river. The streets towards the river are narrow and irregular, but in the higher situations there are many fine terraces and villas. The town has manufacturing of various kinds, including the works of the telegraph maintenance company, engineering works, soap work, chemical works, and a brewery. On account of its picturesque views, its fine air, and its public parks and other attractions, it is one of the favourite resorts of Londoners.

Fronting the river stands the splendid range of buildings in the Grecian style of architecture, formerly known as Greenwich Hospital, but now the Royal Naval College. It occupies the site of an ancient royal palace called Greenwich house, which was a favourite royal residence as early as 1800, but was granted by Henry V to Thomas Beaufort, duke of Exeter, from whom it passed to Humphrey, duke of Gloucester, and it did not revert to the crown till his death in 1433. It was the birthplace of Henry VIII., Queen Mary, and Queen Elizabeth. The building was enlarged by Edward IV., by Henry VIII., who made it his chief residence and named it *Placentia*, by James I., and by Charles I., who erected the "Queen's House" for Henrietta Maria. Along with other royal palaces it was at the Revolution appropriated by the Protector, but it reverted to the crown on the restoration of Charles II., by whom it was pulled down, and the west wing of the present hospital was erected as part of an extensive design which was not further carried out. In its unfinished state it

was assigned by the patent of William and Mary to certain of the great officers of state, as commissioners, for its conversion into a hospital for seamen. As it now stands, the building consists of four blocks. Behind a terrace, 580 feet in length, stretching along the river side, are the buildings erected in the time of Charles II. by Webb from Inigo Jones's designs, and in that of Queen Anne from designs by Sir Christopher Wren, and behind these buildings are on the west those of King William and on the east those of Queen Mary, both from Wren's designs. In the King William range is the painted hall. Its walls and ceiling were painted by Sir Thomas Thornhill with various emblematic devices, and it is hung with portraits of the most distinguished admirals, and paintings of the principal naval battles of England. In the centre of the principal quadrangle of the hospital there is a fine stone of marble taken from the French by Admiral Sir George Rooke. The oldest part of the building was in some measure rebuilt in 1811, and the present chapel was erected to replace one destroyed by fire in 1779. The endowments of the hospital were increased at various periods from bequests and forfeited estates. Formerly 3000 retired seamen were boarded within it, and 5000 or 8000 others, called out-pensioners, received stipends at various rates out of its funds, but in 1863 an Act was passed empowering the Admiralty to grant liberal pensions in lieu of food and lodging to such of the inmates as were willing to quit the hospital, and in 1860 another Act was passed making their leaving on these conditions compulsory. It has since been devoted to the accommodation of the students of the Royal Naval College, for which purpose it was formally opened in 1875. Behind the College is the Royal Hospital School, where 1000 boys, sons of petty officers and seamen, are boarded.

Another of the attractions of Greenwich is the park, 190 acres in extent, in which is situated the Royal Observatory. It was enclosed by Humphrey, duke of Gloucester, in 1338, and laid out by Charles II. It still contains a fine avenue of Spanish chestnuts planted in his time, and the hill rising towards the south commands a fine prospect over London, the Thames, and the plains of Essex. The Royal Observatory was built in 1675, for the advancement of navigation and nautical astronomy. From it the exact time is conveyed at one o'clock every day by electric current to London and all the other chief towns of the kingdom, and English geographers reckon longitude from its meridian. Adjoining Greenwich Park is Blackheath, an open common much frequented by excursionists, and also used for golf and cricket.

Greenwich possesses a considerable number of almshouses and other charitable foundations, among which may be mentioned Queen Elizabeth's College, Trinity Hospital, founded by Henry Howard, earl of Northampton, in 1618; the Jubilee Almshouses, founded by subscription of the inhabitants in 1809 in commemoration of the fiftieth anniversary of George II.; the Green Coat School, the Grey Coat School, and the Orphan Girl's School. The parish church is dedicated to St. Alphege, archbishop of Canterbury, who suffered martyrdom at Greenwich.

Greenwich is first noticed in the reign of Ethelred, when it was from 1011 to 1014 the station of the Danish fleet. It has been the place of debarkation of many illustrious personages, as well as in 1806, after the battle of Waterloo, of the remains of Lord Nelson, which lay in state in the painted hall of the hospital previous to their removal for interment in St. Paul's Cathedral. In 1677 it retained two burgesses to parliament, but it was not again represented till the unique privilege was conferred on it by the Reform Act of 1832. The population of the parish in 1871 was 60,418. The population of the parliamentary borough—whose limits were extended in 1888, and include the parishes of Charlton near Woolwich, Plumstead, and St. Nicholas and St. Paul, Deptford, and part of Woolwich—is 169,867, and the area 5681 acres, of which 957 is in Surrey.

GRÉGOIRE, HENRI (1750–1831), bishop of Blois and French revolutionist, was born at Vêho near Lunéville, 4th December 1750. After studying at Metz and Nancy, he became curé of Embarmesnil and professor at the college of Pont-a-Mousson. In 1783 he was crowned by the academy of Nancy for his *Éloge de la Poésie*, and in 1788 by that of Metz for an *Essai sur la régénération physique et morale des Juifs*. He was chosen in 1789 by the clergy of the district of Nancy to represent them in the states-general, where he took a leading part in the deliberations, and gave energetic support to the republicans. Along with four other curés he abandoned his office and joined that of the *tiers état*; he presided at the permanent sitting of sixty-two hours while the Bastille was being attacked by the people, and made a vehement speech against the enemies of the republic, and he subsequently took a prominent share in abolishing the privileges of birth and religion. Under the new constitution of the clergy he was chosen bishop by the department of Lou-st-Che, taking the title of bishop of Blois. As a member of the national assembly he proposed the motion for the abolition of the king's office, which was carried by acclamation. During the reign of Louis XVI. being absent with other three colleagues on a mission for the union of Saxony and France, he along with them wrote a letter urging the condemnation of the king, but omitting the words *à mort*, and he endeavoured to save the life of the king by proposing in the assembly that the penalty of death be suspended. His subsequent action was very influential in moderating extreme republican views; he opposed the national annihilation of Christianity, and was the first to advocate the reopening of the churches, exerted himself to get measures put in execution for restraining the vandalical fury against the monuments of art, extended his protection to artists and men of letters, and obtained for them pecuniary encouragement from the state, and devoted much of his attention to the reorganization of the public libraries, the establishment of botanical gardens, and the improvement of technical education. He also took a great interest in negro emancipation, and on his motion most of colour in the French colonies were admitted to the same rights as whites. On the establishment of the new constitution, Grégoire was elected to the council of 500, and after the 18th Brumaire he became a member of the new legislative assembly. In this capacity he voted in the minority of five against the proclamation of the empire, and opposed the creation of the new nobility and the divorce of Napoleon from Josephine, but notwithstanding this he was subsequently created a count of the empire and officer of the legion of honour. During the last years of Napoleon's reign he travelled in England and Germany, but in 1814 he had returned to France and was one of the chief instigators of the action that was taken against the empire. After the second restoration he was excluded from the Institute, and when in 1819 he was elected to the assembly by the department of Isère, his election was annulled. From that time, therefore, he lived in retirement, occupying himself in literary pursuits and conducting a voluminous correspondence with most of the eminent savants of Europe, but as he had been deprived of his bishopric and of his pension as a senator, he was compelled to sell his library to obtain the means of support. He died at Paris, May 20, 1831. As he had remained steadfast to his republican principles the ecclesiastical authorities refused him the last offices of religion, and the rites of Christian sepulture, but through the intervention of the civil power mass was said over his body in the church of the Abbaye aux Bœufs by a proscribed priest, and after the hearse set out from the church the populace unyoked the horses and themselves drew it to the cemetery of Mont Parnasse. Grégoire forms a striking exception to most of the French

revolutionists in combining zeal for republicanism with a moderation which sought to check every form of licence, and with a steadfast adherence to the religion of which he was a priest, and it was further a remarkable feature of his character that, though a sincere Roman Catholic, he was thoroughly tolerant of the religious views of others.

Under several political pamphlets, Gregoire was the author of *Histoire des sectes religieuses, depuis le commencement du siècle dernier jusqu'à l'époque actuelle*, 2 vols., 1809, *Les hommes sur la tribune de l'église, 1818*, *De l'influence du Christ sur l'humanité au commencement des siècles*, 1821, *Mémoires des confesseurs, des empereurs, des rois, et d'autres princes*, 1824, *Histoire du sage et du pape en France*, 1826, *Gregoire, curé, évêque, député, candidat, des notables, et des cardes de M. Le Comte de Valois*, *Gregoire*, preceded by a biographical notice by Cousin d'Avallon, was published in 1821, and the *discours ecclésiastiques, politique, et littéraires de Gregoire*, with a biographical notice by H. Guizot, appeared in 1846.

TOPIANS, vol. iv p. 613

GREGORY, ST, surnamed THE GREAT (c. 540-604), the first pope of that name, and one of the four doctors of the Latin Church (Ambrose, Augustine, and Jerome being the other three), was born at Rome about the year 540. His father Gaudianus possessed senatorial rank, and his mother Sylvia is said to have been remarkable for her mental endowments. Educated for the legal profession, Gregory about his thirteenth year was chosen by the citizens to the high position of *pætor urbanus*, this post he is said to have occupied for three years (571-574), discharging its duties with great pomp and magnificence, but on the death of his father, having become deeply impressed with a sense of the transitoriness and vanity of all earthly things, he retired from public life and gave up his whole fortune to pious uses, building six monasteries in Sicily and one in Rome, in this last, which was dedicated by him to St Andrew, he embraced the Benedictine rule, and divided his whole time between works of charity and the exercises of fasting, meditation, and prayer. It was while he was still a simple monk of St Andrew that the often repeated incident related by Bede is believed to have occurred. Having seen some English slaves of striking beauty exposed for sale in the public market, "non Angli sed Angli," he set his heart upon the evangelization of Britain, and was only prevented by the command of his ecclesiastical superiors from setting out in person to seek the realization of his pious wish. About 578 or 579 he was appointed abbot of his monastery, and likewise one of the seven deacons (regentium) of the Roman Church, and in 582 he was sent by Pelagius II. to Constantinople as papal apocrisarius or representative at the imperial court. There he remained for upwards of three years, during which he negotiated several matters of importance and delicacy, but amid his diplomatic and other engagements he found time to begin, if not even to complete, one of his largest works, the *Moralia*, or exposition of the book of Job. A few years after his return from the Eastern capital, the death of Pelagius (590) caused a vacancy in the papal chair, and the choice of the clergy, senate, and people unanimously fell upon Gregory. He strongly deprecated the bestowal of this honour, and wrote to the emperor (Maurice) imploring him not to confirm the nomination. A pious fraud, committed by the city priest then in office, prevented the letter from reaching its destination, and though Gregory had himself for a time, he was at length obliged to yield to the urgency of his friends by accepting the papal crown (September 590). The pontificate of fourteen years which followed was marked by extraordinary vigour and activity, which made themselves felt throughout almost every department of the doctrine, discipline, and worship of the entire Western Church. By means of earnest prayer and wisely ex-

pended pains the aggressions of the Lombards were checked, and order and tranquility were speedily restored to Rome, in Italy and France he tightened the too long relaxed reins of ecclesiastical discipline, in England, Spain, and Africa the powers of Paganism, Arianism, and Donatism were perceptibly weakened, as against the Eastern emperor and the patriarch of Constantinople the prerogatives of the bishop of Rome were asserted with a vigour previously unwitnessed, the ceremonies of the church were regulated and extended, the liturgy further developed. The anniversary of Gregory's death, which took place at Rome on the 12th of March 604 is observed as a duplex by the Latin Church, and even in the Greek Church his veneration and sanctity continue to be commemorated. The hyperbolic panegyrics of those ecclesiastical writers who lived nearest his time (such as Gregory of Tours and Isidore of Seville) must of course be taken with considerable reservation, but they are interesting as showing how powerful and profound was the impression he left upon his contemporaries and immediate successors—an impression and an influence well entitling him to the epithet of "great." Of the personal qualities of Gregory, the most obvious are beyond all question the angular strength and energy of his character. Fully and intensely convinced of the divineness of the Christian doctrine and life as then presented to him, he owes to his mind and heart, he suffered no obstacle and no discouragement to triumph over his determination to give them all the currency and prevalence that was possible in his day. Having clearly seen the end he had in view, he with equal discernment made choice of his measures for its attainment. The refinements alike of literature and of art had for him no place in the Christian scheme, it is needless to say that he therefore despised them both for himself and for others. There is some room for hoping indeed that the burning of the books of the Palatine library was due to some such partiality, but there is no possibility of mistake as to the literary taste of the man who could write (pref. to *Moralia*)—"non metatemi collusionem fugio, non barbarum confusionem deviso, situs molusque etiam et propositum casus servare contemno, quam indignum vehementer existimo ne verba celestia oculis restingam sub igitibus Donati." The uniformity of the Roman ritual, the ascendancy of the Roman hierarchy, the prevalence of the Catholic dogma,—these were not merely the highest, they were the only, ideals he had ever caught sight of. It ought not therefore to surprise us if in striving towards them he sometimes was tempted, and yielded to the temptation, to sacrifice truthfulness to what he conceived to be the truth, and the mere claims of humanity to the demands of what he regarded as a higher law. Never purely selfish, he was swayed from the exigencies of his ecclesiastical position, singularly tolerant, liberal, and kindly.

Of the numerous extant works attributed to Gregory the Great the following are undisputed:—the *Moralia*, in thirty-five books, being an exposition of the book of Job, composed between 590 and 600, the twenty-two *Homilies on Ezekiel* (about 595), and the forty *Homilies on the Gospels* (about 593), the *Regula* (or *Can*) *Patrum* addressed to John, archbishop of Ravenna (about 590), the *Diallogues* with the deacon, in four books, on the lives and miracles of the Italian saints (585 or 594), and the *Letters*, in four teen "registers," arranged according to the ease of memorization. He was also the author of various hymned hymns, none of which are still extant and appear in the collected editions of his works. They are characterized more by simplicity of language than by depth of feeling. The *Concordia quorundam testamentorum* (an early version of the Vulgate), and also the *Commentarii* on I Kings, Chronicles, and the seven penitential psalms usually ascribed to him, are spurious. His liturgical works, the *Decretum* and *Amplius* *in usum*, have been considerably tampered with by medieval collectors and revisers, and even the *Letters* are not wholly free from interpolations. Of Gregory's manner of composition little need be said, he avowedly adopts in all cases the allegorical method, which in his hands is unflinchingly carried out, with, in many cases,

him. At length, in 1073, on the death of Alexander, Hildebrand was himself as it were compelled by the tumultuous demands of the mob to accept the vacant throne (23d April), but he refused to receive consecration until the sanction of the emperor had been obtained. This did not arrive for more than a month, although meanwhile he had been practically exercising many of the papal functions, finally, however, he was ordained to the priesthood, and some days afterwards (30th June) solemnly consecrated pope by the title of Gregory VII., a name which he chose in testimony of his veneration for the memory and character of his earliest patron, Gregory VI.¹ Once firmly established on the papal throne, Gregory lost no time in giving the utmost possible practical effect to the two leading ideas of his life, the establishment of the supremacy of the papacy within the church, and the effective assertion of the supremacy of the church over the state. In March 1074 a synod was held in Rome which condemned the simony that had grown so prevalent throughout the church, and also enacted the old stringent laws of celibacy which had become almost a dead letter, especially in Germany and in the north of Italy, and monachal or married priests were declared to be degraded and their priestly functions invalid. The resistance of the clergy to these decrees was utterly in vain, papal legates visited every country, and, supported by the popular voice, compelled submission. At a second synod held in Rome in February 1075 the decrees of the first were confirmed, and the first blow was struck which afterwards resulted in the long protracted wars of investitures. At that synod it was determined that any ecclesiastic who in future should accept office from the hands of a layman incurred the penalty of deposition, while the secular lord who bestowed investiture was to be excommunicated. The decree was aimed immediately at certain German bishops, Henry's personal advisers, but hardly less directly at Henry himself. The emperor, finding his hands at the moment fully occupied with the suppression of a revolt among the Saxons, was politic enough to conceal his resentment for the time, and to dismiss his advisers, but as soon as the war had been brought to a close, his defiance found ample expression. Meanwhile Gregory was not unopposed even in Italy, and during the Christmas festivities of 1075 a revolt in Rome itself was organized by Cencius, who had placed himself at the head of those nobles who were opposed to reform. The pope, however, had the support of the commons on his side, and ultimately the insurgents were compelled to fly. A papal embassy was next sent, early in 1076, to Henry at Goslar, citing him to appear personally at Rome at a council to be held in the second week of Lent, and there answer for his simony, sacrilege, and oppression. Henry's rage at this knew no bounds, he dismissed the legates with insult, and at a diet held at Worms (24th January 1076) replied by declaring Gregory deposed on charges of tyranny, magic, and adultery, by sending notification of this fact to the Roman clergy, and by taking steps for appointing a successor to the deposed pontiff. Gregory now lost no time in excommunicating all the bishops who had attended the diet of Worms, in solemnly deposing and excommunicating the emperor, and in absolving his subjects from their oath of allegiance (22d February 1076). This counter action produced a powerful effect upon the German princes and people, many of whom had had good cause to resent Henry's tyrannies, one by one the bishops who had announced their withdrawal from Gregory's obedience now signified their contrition, and at a diet held at Tribur (September 1076) the election of a new

emperor began to be discussed. Resistance being in the measure impossible, Henry resolved upon humbling himself to the utmost, in the dead of winter he set out to make his submission, Gregory was in waiting for him at Canossa, where (25th to 27th January 1077) that famous penance which Europe has not yet forgotten was imposed (see vol. x p. 488). Absolved only on condition of his not assuming the royal dignity till his case had been investigated and decided, Henry had no sooner left the papal presence than he began to plot his revenge. Throwing himself upon the generosity of his Lombard vassals, he took courage to face the papal excommunication, which was renewed in November 1078, and in the wars which ensued his arms were finally successful. Rudolf of Swabia having died soon after the battle of Mersburg in 1080, the emperor proceeded with a powerful army to escort into Italy Guibert of Ravenna, who had been chosen at Brixen (June 1080) as Gregory's successor. In three successive summers the attack on Rome was renewed, but it was not until 1084 (March 21) that the treachery of some of the nobles of the city opened the gate to the invader. Gregory was now at last compelled to take refuge in the castle of St. Angelo, while Guibert was proclaimed on the pontifical throne as his successor with the title of Clement III. After receiving occasion from Clement, Henry determined to return at once to Germany, especially as Robert Guiscard was known to be approaching. Released accordingly by the arrival of the Norman duke, Gregory excommunicated once more both Henry and Clement, but not deeming himself secure at Rome, where he had reason to know that his power was no longer what it once had been, he in May 1084 placed himself under Robert's protection at Salerno, where he died, May 25, 1085, after a comparatively brief pontificate of not much more than ten years. His last words were, "I have loved righteousness and hated iniquity, and therefore I die in exile." His festival (duplex) is observed throughout the Roman Church on the anniversary of his death. His successor was Victor III.

The life-work of Hildebrand may be thus summed up in the words of St. James Stephen:—"He found the papacy dependant on the empire, he sustained it by alliances almost commensurate with the Italian peninsula. He found the papacy electoral by the Roman people and clergy, he left it electoral by a college of papal nomination. He found the emperor the virtual patron of the holy see, he wrested that power from his hands. He found the secular clergy the allies and dependants of the secular power, he converted them into the unalienable vassals of his own power. He found the higher ecclesiastics in servitude to the temporal sovereigns, he delivered them from that yoke to subjugate them to the Roman throne. He found the patronage of the church, the most degrading spoil and mechanism of princes, he reduced it within the dominion of the supreme pontiff. He is celebrated as the reformer of the impure and profane abuses of his age, he is more justly entitled to the praise of having left the impress of his own vigorous character on the history of all the ages which have succeeded him."

Unlike Gregory the Great, Hildebrand was no author, his literary remains are all comprised in eleven books of "Registres," of which, though they have often been quoted, the first two are often attributed to him are not now regarded as genuine. Among the numerous earlier biographies may be mentioned those of Paul of Bernart, Pandulf of Pisa, Nicolas of Aigen, and Cardinal Bona. Among later biographies may be mentioned those of Voigt (*Hildebrand als Gregor VII. u. sein Zeitalter*, 1816, 2d ed. 1818, French translation, with introduction and notes, by Jager, 1884, 4th ed. 1886), Borden (*The Life and Pontificate of Gregory VII.*, 1840), Scholl (*Gregor VII.*, 1847), Holstenstein (*Gregor's Polit. Denkwürdigkeiten nach den Streitschriften seiner Zeit*, 1850), Ghica (*Papst Gregor VII. u. sein Zeitalter*, 7 vols., 1859-61), Villemain (*Histoire de Gregoire VII.*, 1873, English translation by Beckley, 1874), Langen (*Gregorius VII. als Papst und als der politischen Weltgenosse*, 1874), and Maltzev (*Gregor VII. u. die Buchvermehrung*, 1876). The events of the period are also very fully treated by W. Giesbrecht in his *Geschichte der deutschen Kaiserzeit*, and in other works. For the papacy, see St. Gregory's VII. *epistolæ et diplomata pontificia, ac vultus ejusdem pontificis et appendices antipontificum colorum et relictorum monumenta porphyreuma Gregorius VII. epistolographi completiora* (1877).

¹ Apart from the rich historical associations connected with the name of Gregory, its etymology (from *εὐφρενεια*), so suggestive of sleepless vigilance, had probably something to do with its selection by him and so many other popes.

GREGORY VIII (Albani de Mora), who as papal legate had in 1172 attended the council of Avranchois, which absolved Henry II of England from the guilt of the murder of Thomas à Beckett, was consecrated pope in room of Urban III October 25th, 1187, and died of fever on December 17th of the same year. Clement III was his successor.

GREGORY IX, pope from 1227 to 1241, the successor of Honorius III, fully inherited the traditions of Gregory VII and of his uncle Innocent III, and resolutely gave himself up to the perpetuation of their policy. One of the first acts of his pontificate was to suspend the emperor Frederick II, then lying sick at Otranto, for dilatoriness in carrying out his promised crusade, the suspension was followed by excommunication and threats of deposition after Frederick had written to the sovereigns of Europe complaining of his treatment. A consequent invasion of the patrimony of St Peter at the instance of Frederick in 1228 having proved unsuccessful, the emperor was constrained to give in his submission and beg for absolution. Although peace was thus secured (August 1230) for a season, the Roman people were far from satisfied, driven by a revolt from their own capital in July 1232, the pope was compelled to take refuge at Anagni and invoke the aid of Frederick. A new outbreak of hostility led to a fresh excommunication of the emperor in 1239, and to a prolonged war which was only terminated by the death of Gregory (August 22, 1241). This pope, who was a remarkably skilful and learned lawyer, caused to be prepared in 1234 the well known *Novus Compilatio Decretalium*, printed at Mainz in 1473. He it was who canonized Saints Elizabeth, Dominic, and Antony of Padua, and also Francis of Assisi, of whom he had been a personal friend. His encroachments upon the rights of the English Church during the ignominious reign of Henry III are well known, but similar attempts against the liberties of the national church of France only served to call forth the celebrated Pragmatic Sanction of St Louis. Gregory IX was succeeded by Celestine V.

GREGORY X, pope from 1271 to 1276, succeeded Clement IV after the papal chair had been three years vacant, his election occurred while he was engaged in a pilgrimage to Saint Jean-d'Acre. On his arrival at Rome his first act was to summon the council which met at Lyons in 1274 for the purpose of considering the Eastern schism, the condition of the Holy Land, and the abuses of the Catholic Church. It was while returning from that council that he died at Arezzo on the 10th of January 1276. To him is due the bull which, subsequently incorporated into the code of canon law, continues to regulate all conclaves for papal elections. He was succeeded by Innocent V.

GREGORY XI (Pierre Roger de Beaufort), pope from 1270 to 1378, born in Limousin in 1336, succeeded Urban V in 1370 as one of the Avignon popes. During his pontificate vigorous measures were taken against the "heresies" which had broken out in Germany, England, and other parts of Europe, a sincere effort was also made to bring about a reformation in the various monastic orders. The nineteen propositions of Wickliffe and the thirteen articles of the "Sachsenspiegel" were formally condemned by him in 1373. His energy was largely stimulated by the stirring words of Catherine of Siena (see vol v p 231), to whom in particular the transference of the papal see back to Italy, January 27, 1377, was almost entirely due. He did not long survive this removal, dying on March 27, 1378. His successor was Urban VI, but the antipope Clement VII also received much support, and the schism lasted forty years.

GREGORY XII (Angelo Corario or Corario), pope from 1406 to 1409, born at Venice about 1326, suc-

ceeded Innocent VII on 30th November 1406, having been chosen at Rome by a conclave consisting of only fifteen cardinals, under the express condition that should Benedict XIII of Avignon renounce all claim to the papacy, he also would renounce his, so that a fresh election might be made by the no longer divided church. Along with Benedict he was deposed by the council of Pisa in March 1409 as schismatical, heretical, perjured, and scandalous, but it was not till after the council of Constance had set aside John XXIII (1415) that through his ambassador he formally renounced the title and dignity of lawful pope. The rest of his life was spent in peaceful obscurity as cardinal-bishop of Porto and legate of the mark of Ancona. He died October 18, 1417, having been succeeded in 1409 by Alexander V.

GREGORY XIII (Ugo Buoncompagni), pope from 1572 to 1585, was born February 7, 1502, at Bologna, where he studied law and graduated in 1530, and afterwards taught jurisprudence for some years, Alexander Farnese and Charles Borromeo being among his pupils. At the age of thirty-six he was summoned to Rome by Paul III under whom he held successive appointments as first judge of the capital, abbreviator, and vice-chancellor of the consistory. By Paul IV he was attached as datarius to the suite of Cardinal Cafa, and by Pius IV he was created cardinal priest and sent to the council of Trent. On the death of Pius V in May 1572, the choice of the conclave fell upon Buoncompagni, who assumed the name of Gregory XIII. His intervention in the affairs of Britain through Ireland and by means of his tool Philip II, and also the league which he sought to cement against France (the massacre of the St. Bartholomew had taken place in September 1572), are matters which belong to the history of those countries. In order to raise funds for these and similar objects, he confiscated a large proportion of the houses and properties throughout the states of the church,—a measure which enriched his treasury, indeed, for a time, but by alienating the great body of the nobility and gentry, revived old factions, created new ones, and ultimately plunged his temporal dominions into a state bordering upon anarchy. Such was the position of matters at the time of his death, which took place on the 10th of April 1585. He was a liberal patron of the Jesuit order, for which he founded many new colleges, the new and greatly improved edition of the *Corpus juris canonici* was also due to his care, but the work with which the name of Gregory XIII is most intimately and honourably associated is that of the reformation of the calendar, which has been already described under that heading (vol iv p 671). Gregory XIII was succeeded by Sixtus V.

GREGORY XIV (Niccolo Sfondrati), pope from 1590 to 1591, a native of Cremona, succeeded Urban VII, 5th December 1590. As a monk he had been eminent for the decency and sobriety of his life, but his brief pontificate was marked by no important occurrence, except that, instigated by the king of Spain and the duke of Mayenne, he excommunicated Henry IV of France, declaring him, as a heretic and persecutor, to be deprived of his dominions, and also levied an army for the invasion of France. The history of that country records how this proceeding was regarded alike by clergy, parliament, and people. The biographers mention as a curious personal trait of Gregory XIV a nervous tendency to laughter which occasionally became irresistible, and which manifested itself even at his coronation. He was succeeded by Innocent IX.

GREGORY XV (Alessandro Ludovisi), pope from 1621 to 1623, born at Bologna in 1554, succeeded Paul V on the 9th of February 1621. Beyond assisting the German emperor against the Protestants, and the king of Poland against the Turks, he interfered little in European

politics. He was a learned divine and manifested a reforming spirit, and his pontificate was marked by the canonization of St. Theresa, Francis Xavier, Ignatius Loyola, and Philip Neri. He died on the 18th of July 1623, and was succeeded by Urban VIII.

GREGORY XVI. (Basilomonte Alberto Cappellari), pope from 1831 to 1846, was born at Belluno on September 18, 1765, and at an early age entered the order of the Camaldoli, among whom he rapidly gained distinction for his theological and linguistic acquirements. His first appearance before a wider public was in 1799, when he published against the Italian Jacobins a controversial work entitled *Trionfo della Santa Sede*, which, besides passing through several editions in Italy, was translated into several European languages. In 1800 he became a member of the Academy of the Catholic Religion, founded by Pius VII., to which he contributed a number of memoirs on theological and philosophical questions. When Pius VII. was carried off from Rome in 1809, Cappellari withdrew to the monastery of San Michele at Murano, near Venice, and in 1814, with some other members of his order, he removed to Padua, but soon after the restoration of the pope he was recalled to Rome, where he received successive appointments as vicar-general of the Camaldoli, councillor of the Papal Curia, prefect of the Propaganda, and examiner of bishops. In March 1825 he was created cardinal by Leo XII., and shortly afterwards was entrusted with an important mission to adjust a concordat regarding the interests of the Catholics of Belgium and the Protestants of Holland. On the 21 February 1831 he was, after sixty-four days' conclave, unexpectedly chosen to succeed Pius VIII. in the papal chair. The revolution of 1830 had just inflicted a severe blow on the ecclesiastical party in France, and it seemed as if similar disasters to the papal cause were imminent in other parts of Europe, when Gregory XVI. entered upon his fifteen years' pontificate. Almost the first act of the new Government of France was to forbid the troops in Ancona, and the immediate effect was to throw all Italy, and particularly the Papal States, into a state of excitement such as seemed to call for strongly repressive measures. In the course of the struggle which ensued, the temporal reign of Gregory was marked accordingly by executions, banishments, imprisonments, to an extent which makes it impossible for the candid reader to absolve him from the charges of cruelty and bigotry which were so frequently raised at the time. The embarrassed financial condition in which he left the States of the Church also makes it doubtful how far his lavish expenditure in architectural and engineering works, and his magnificent patronage of learning in the hands of Mas, Mezzofanti, and others, was for the real benefit of his subjects. The years of his pontificate were marked by the steady development and diffusion of the ultramontane ideas which were ultimately formulated under the presidency of his successor Pius IX. by the council of the Vatican. He died 1st June 1846.

GREGORY, ST., THE ILLUMINATOR (in Armenian *Gregor Lusavorich*, in Greek *Gregor von Phosor* or *Photios*), the founder and patron saint of the Armenian Church, was born about 287 A.D. He belonged to the royal race of the Arsacides, being the son of a certain Pinnos Anak, who assassinated Choroene of Armenia, and thus brought ruin on himself and his family. His mother's name was Okhke, and the Armenian biographers tell how the first Christian influence he received was at the time of his conception, which took place near the monument raised to the memory of the holy apostle Thaddæus. Educated by a Christian nobleman, Euthalius, in Caesarea in Cappadocia, Gregory sought, when he came to man's estate, to introduce the Christian doctrine into his native land. At that time

Tiridates I., a son of Chosroes, sat on the throne, and, influenced partly it may be by the fact that Gregory was the son of his father's enemy, he subjected him to much cruel usage, and imprisoned him for fourteen years. It would be useless to relate the various forms of torture which the orthodox accounts represent the saint to have endured without permanent hurt, almost any one of his twelve trials would have been certain death to an ordinary mortal. But vengeance and indignation fell on the king, and at length Gregory was called forth from his pit to restore his royal persecutor to reason by virtue of his saintly intercession. The cause of Christianity was now secured, king and princes and people vied with each other in obedience to Gregory's instruction, and convents, churches, and schools were established. Gregory in 302 received consecration as patriarch of Armenia from Leontius of Caesarea, and in 318 he appointed his son Auxustus to be his successor. About 331 he withdrew to a cave in the mountain Sebuh in the province of Diarrhachia in Upper Armenia, and there he died a few years afterwards unattended and unobserved. When it was discovered that he was dead his corpse was removed to the village of Thordanum or Thortan. The remains of the saint were scattered far and near in the reign of Zeno the Great he is said to be now in Italy, his right hand at Bethlehem, and his left at Sic. It is almost impossible to get at Gregory's real personality through the tangled growth of ecclesiastical legend, but he would appear to have possessed some of that combination of expediency which is so frequently of service to the reformer. While he did his best to undermine their system, he left the pagan priests in enjoyment of their accustomed revenues.

A number of homilies, possibly spurious, several psalms, and about thirty of the essays of the Armenian Church are ascribed to Gregory. The homilies appear for the first time in a work called *Homologemata* at Constantinople in 1784, a century after which a Greek translation was published at Venice by the Melchites, and they have since been edited in German by J. M. Schmid (Rastenburg, 1872). The original authorities for Gregory's life are Eusebius, whose *History of Tundates* was published by the Archbishop in 1856, Moses of Chosroes, *Historia Armenorum*, and Simon Metaphrasis. *A Life of Gregory* by the venerated Athanasius, published in Armenian at Venice in 1749, was translated into English by Rev. S. O. Malan, 1868. See also Bancroft, *History of the life of St. Gregory*, 1717; Neumann, *Gesch. des Armenischen Literatur*, 1835; and Dulaupre, *Hist. des dogmes, &c., de l'Eglise Armenienne*, 1869.

GREGORY, ST., or NAZIANZUS, surnamed THEOLOGUS, one of the four great fathers of the Eastern Church, was born about the year 329 A.D. at or near Nazianzus, Cappadocia. His father, also named Gregory, a convert from Hellenism, had lately become bishop of the diocese, his mother Nonna, an eminently pious woman, by whom he was dedicated to the service of God from his birth appears to have exercised a powerful influence over the religious convictions of both father and son. In pursuit of a more liberal and extended culture than could be procured in the insignificant town of Nazianzus, Gregory visited successively the cities of Caesarea, Alexandria, and Athens, as a student of grammar, mathematics, rhetoric, and philosophy, at the last-named seat of learning, where he prolonged his stay until he had entered his thirtieth year, he enjoyed the society and friendship of Basil, who afterwards became the famous bishop of Caesarea, the prince Julian, destined soon afterwards to play so prominent a part in the world's history, was also a fellow-student. Shortly after his return to his father's house at Nazianzus (about the year 360) Gregory received baptism, and renewed his dedication to the service of religion, he still continued, however, for some time, and indeed more or less throughout his whole life, in a state of hesitation as to the form which that service ought to take. He was inclined by nature and education to a contemplative life spent among books and in the society of congenial friends, he was yet continually urged by outward circumstances,

and doubtless also by some inward call, to active pastoral labour. The spirit of refined intellectual monasticism, which clung to him through life and never ceased to struggle for the ascendancy, was about that time strongly encouraged by his intercourse with Basil, who was then revelling in the exalted pleasures of his retirement in Pontus, the preparation of the *philocalia*, a sort of chrestomathy compiled by the two friends from the writings of Origen, belongs to this period. But the events which were at that time stirring the political and ecclesiastical life of Cappadocia, and indeed of the whole Roman world, made a career of learned leisure difficult if not impossible to a man of Gregory's position and temperament. The emperor Constantius, having by a course of awful intrigue and intimidation succeeded in thus using a semi-Asian formula upon the Western bishops assembled at Ariminum in Italy, had next attempted to follow the same course with the Eastern episcopate. The aged bishop of Nazianzus having yielded to the imperial threats, a great storm arose among the monks of the diocese, which was only quelled by the influence of the younger Gregory, who shortly afterwards (about 361) was ordained to the priesthood. After a vain attempt to evade his new duties and responsibilities by flight, he appears to have continued to act as a presbyter in his father's diocese without interruption for some considerable time, and it is probable that his two *Invectives against Julian* are to be assigned to this period. Subsequently (about 373), under a pressure which he somewhat resented, he allowed himself to be nominated by Basil as bishop of Sasima, a miserable little village some 32 miles from Tyana, but he seems hardly, if at all, to have assumed the duties of this diocese, for after another interval of "flight" we find him once more (about 373-3) at Nazianzus, assisting his aged father, on whose death (374) he retired to Seleucia in Issauria for a period of some years. Meanwhile a more important field for his activities was opening up. Towards 378-9 the small and depressed remnant of the orthodox party in Constantinople sent him an urgent summons to undertake the task of rescuing the catholic cause, so long persecuted and borne down by the Arians of the capital. With the accession of Theodosius to the imperial throne, the prospect of success to the Nicene doctrine had dawned, it only it could find some courageous and devoted champion. The fame of Gregory as a learned and eloquent disciple of Origen, and still more of Athanasius, pointed him out as such a defender, nor could he resist the appeal made to him, although he took the step solely against his will. Once arrived in Constantinople, he laboured so zealously and well that the orthodox party speedily gathered strength, and the small apartment in which they had been accustomed to meet was soon exchanged for a vast and celebrated church which received the significant name of Anastasia, the Church of the Resurrection. Among the hearers of Gregory were to be found, not only churchmen like Jerome and Evagrius, but also heretics and heathens, and it says much for the sound wisdom and practical tact of the preacher that from the outset he set himself less to build up and defend a doctrinal position than to urge his flock to the cultivation of the loving Christian spirit which cherishes higher aims than mere heresy hunting or endless disputation. Doctrinal, nevertheless, he was, as is abundantly shown by the famous five discourses on the Trinity, which earned for him the distinctive appellation of *Θεολόγος* (*theologos* being here used in the stricter sense to designate the doctrine of Christianity, as distinguished from *θεωλογία*, which denotes the doctrine of His incarnation). He continued to labour in the Eastern capital till the arrival of Theodosius, and the visible triumph of the orthodox cause, the metropolitan see was then conferred upon him, and after the assembling of the second oecumenical council in 381 he received consecration from

Miletus. In consequence, however, of a spirit of discord and envy which had manifested itself in connection with this promotion, he soon afterwards, in an oration, not without some bitterness of tone, resigned his dignity, and withdrew into comparative retirement. The rest of his days were spent partly at Nazianzus, where he appears still to have mixed himself in ecclesiastical affairs, and partly on his patrimonial estate at Anianzus, where he devoted himself to his favourite literary pursuits, and especially to poetical composition, until his death, which occurred in 390 or 390. His festival is celebrated in the Eastern Church on January 25th and 30th, in the Western on 9th May (duple).

His extant works consist of poems, epistles, and orations. The poems, which include epigrams, elegies, and an autobiographical sketch, have been frequently printed, the *editio princeps* being the Aldine (1604). Other editions are those of Tollus (1696) and Muretor (1709), a volume of *Classicus Selecta* also has been edited by Dronke (1840). The largely entitled *κρυπτα ἀνδρος* usually included is certainly not genuine. Of Gregory's poetry there is not much to be said. His best energies were not devoted to it, it was adopted in his later years as a recreation rather than as a serious pursuit, thus it is occasionally delicate, graphic, beautiful, as could not fail to be the case with a writer of his culture and power, but it is not sustained. Of the hymns none have proved of use to ecclesiastical use. The letters are the highest piece of his literature. They are always easy and natural, and thus is not infrequently forced in the manner in which they are, witty, and profound sayings are introduced. As an orator he is said to have surpassed all his contemporaries. "In the purity of his discourse, his nobleness of his expressions, the ornaments of his language, the variety of his figures, the majesty of his comparisons, the beauty of his reasoning, and the sublimity of his thoughts." The oration possessed neither of Basil's gift of government nor of Gregory of Nyssa's power of speculative thought, he worthily takes a place in that triumvirate of Cappadocians whom the Catholic Church gratefully recognises as having been, during the critical struggles in the latter half of the 4th century, the best defenders of its faith. The *Opera Omnia* were first published by Hieronymus (Paris, 1564, 1570), the subsequent editions have been those of Billius (Paris, 1694, 1811), and of the *Classique Monach*, 1840, of the *Benedictine*, 1840, 1878, but interrupted by the French Revolution and not completed until 1810, Cullen being the final editor), and of Migne.

Scattered notices of the life of Gregory Nazianzen are to be found in the writings of Basil, Eusebius, Theodoret, and Rufinus, as well as in his own letters and poems. The data derived from these sources are not always in agreement with the accounts of biographers. The earliest modern authorities such as Tilliott (*Class. Lat.* i. 15) and Leclerc (*Bibl. Univ.* i. 271) have been made up by Gibson in which he adds much of the fabric. Among recent biographers may be mentioned those of Ullmann (*Gregorius von Nazianz*, 1822), Engeström by G. F. Cox, M. A. (1867), Bénédict (*St. Grégoire de Nazianze*, in *rev. et corr. de son époque* 1877), and Mouton (*Levite et évêque de ses origines à ses dernières années* in *St. Grégoire de Nazianze*, 1878).

GREGORY, EN, or NYSSA, one of the great Cappadocians, and designated by one of the later oecumenical councils as "a father of fathers," was a younger brother of St Basil, and was born (probably) at Neocaesarea about 331. A D For his education, which was the best that could be got at that time, he appears to have been chiefly indebted to his older brother Basil. At a comparatively early age he entered the church, and held for some time the office of anagnost or reader, subsequently he manifested a desire to devote him self to the secular life as a rhetorician, but this impulse was checked by the earnest remonstrances of Gregory Nazianzen. Finally, in 371 or 372 he was ordained by his brother Basil to the bishopric of Nyssa, a small town in Cappadocia. Here he is usually said (but on inadequate data) to have adopted the opinion then gaining ground in favour of the celibacy of the clergy, and to have separated from his wife Theosebida, who became a deaconess in the church. His strict orthodoxy on the subject of the Trinity and the Incarnation, together with his vigorous eloquence, combined to make him peculiarly obnoxious to the Arian faction, which was at that time in the ascendant through the protection of the emperor Valens, and in 376, on the ground of alleged irregularities in his election, and the administration of the finances of his diocese, he was driven into exile, whence he did not return till the publication of the edict of Gratian in 378. Shortly afterwards he took part

in the proceedings of the synod which met at Antioch in Oais, principally in connection with the Meletian schism. At the great oecumenical council held at Constantinople in 381, he was a conspicuous champion of the orthodox faith, according to Nicephorus, indeed, the additions made to the Nicene creed were entirely due to his suggestion, but this statement is of doubtful authority. That his eloquence was highly appreciated is shown by the facts that he pronounced the discourse at the consecration of Gregory of Nazianzus, and that he was chosen to deliver the funeral oration on the death of Meletius the first president of the council. In the following year, moreover (383), he was commissioned by the emperor to inspect and to order the churches of Arabia, in connexion with which mission he also visited Jerusalem. The impressions he gathered from this journey may, in part at least, be gathered from his famous letter *De Euthymio Hierosolyma*, in which an opinion strongly unfavourable to pilgrimages is expressed. In 383 he was probably again in Constantinople, where in 385 he pronounced the funeral orations of the princess Pulcheria and afterwards of the empress Placidia. Once more we read of him in 394 as having been present in that metropolis at the synod held under the presidency of Nectarius to settle a controversy which had arisen among the bishops of Arabia, in the same year he assisted at the consecration of the fine new cathedral at the expense of his acquiescence. His occasion there is reason to believe that his discourse commonly but wrongly known as that *εἰς τὴν λαοὶν ὑποτακτοῦ* was delivered. The exact date of his death is unknown, some authorities refer it to 396, others to 400. His festival is observed by the Greek Church on January 10th, in the Western martyrologies he is commemorated on March 9th.

Gregory of Nyssa is generally admitted to have excelled both his brother Basil and Gregory of Nazianzus alike in the natural vigour of his intellect and in the extent of his acquirements. His teaching though strictly Christian, shows considerable freedom and originality of thought, in many points his mental and spiritual affinities with Origen show themselves with advantage, though in one particular—namely, in his doctrine of *transmigration* or final restoration—his views have since been repudiated by the orthodox. His style has been frequently praised by competent authorities for sweetness, richness, and elegance. His numerous works may be classed under five heads—(1.) Treatises in doctrinal and polemical theology. Of these the most important is that *Against Eunomius* in twelve books. Its doctrinal thesis (which is supported with great philosophical acumen and rhetorical power) is the divinity and consubstantiality of the Word, in the other the chief object is to show which Eunomius had ascribed, in undivided, and the heathen himself is held up to scorn and contempt. This is the work which, most probably in a shorter form, was read by its author when at Constantinople before the Gregory Nectarius and Jerome in 383 (*Jerome, De Vir. Ill.* 138). To the same class belong the treatise *To Adamantius*, against the trinitarians, *On Faith*, against the Arians, *On Common Notions*, in explanation of the terms in current employment with regard to the Trinity, *On Syllogisms*, against the Meletians, *To Theophrastus*, against the Apollinarians, an *Autobiography* against the same, *Against Paul*, a disputation with a heathen philosopher, the *Oratio Catechetica Magna*, and the dialogue *De Anima et Resurrectione*. (2.) Practical treatises. To this category belong the treatise *On Virginitas* and *On Pilgrimages*, as also the Canonical *Epistles* upon the rules of penance. (3.) Expository and homiletical works, including the *Hexameron*, and several series of discourses *On the Wisdom of Solomon*, *On the Interpretation of the Psalms*, *On the Sixth Psalm*, *On the first three Chapters of Ecclesiastes*, *On Canticles*, *On the Lord's Prayer*, and *On the Eight Beatitudes*. (4.) Biographical, consisting chiefly of funeral orations. (5.) Letters. The only complete edition of the whole works are those by Fronton le Duc (Fronto Dureau, Paris, 1616, with additions, 1618 and 1688) and by Migne. Of the new edition projected by F. Gieseler only the first volume, containing the *Opera Dogmatica*, has appeared (1866). There have been numerous editions of several single treatises, as for example of the *Oratio Catechetica*, *De Præconibus*, and *De Anima et Resurrectione*. See the monograph by Rupp (*Gregory, des Bischofs von Nyssa, Leben und Verfassungen*, Leipzig, 1856), and the *Deutsche hagiographische theologiae de Greg. Nyss.* (1856), Moller (*Gregorius Nyssæ doctor divini de hominis natura et virtutibus et cum Origena com paratus*, 1854), and Stigler, *Die Psychologie des h. Gregorius von Nyssa* (Rastatt, 1867).

GREGORY, St., surnamed in later ecclesiastical tradition THAUMATURGOS (the miracle-worker), was born of noble and wealthy heathen parents at Neocaesarea, towards the beginning of the 3d century of the Christian era. His original name was Theodorus. Destined by his parents for the bar, he studied civil law at Athens, Alexandria, and Berytus, it is said, he afterwards (about 231) accompanied his sister to Caesarea in Palestine, where he became the pupil and finally the convert of Origen. In returning to Cappadocia some five years after his conversion, it had been his original intention to live a retired ascetic life (Euseb., *II. E.*, vi 30) but this wish was not permitted to gratify. Urged by Origen, and at last almost compelled by Theodinus of Amasia, his metropolitan, neither of whom was willing to see so much learning, piety, and masculine energy practically lost to the church, he, after many attempts to evade the dignity, was consecrated bishop of his native town (about 240). His episcopate, which lasted some thirty years, was characterized by great zeal, and by so much success that, according to the (doubtless somewhat rhetorical) statement of Gregory of Nyssa, whereas at the outset of his labours there were only seventeen Christians in the city, there were at his death only seventeen persons in all who had not embraced Christianity. This result he achieved in spite of the Decian persecution (260), during which he had sought it to be his duty to absent himself from his diocese, and notwithstanding the demoralizing effects of an eruption of barbarians who laid waste the diocese in 260. Gregory, although he has not always escaped the charge of Sabellianism, now holds an undisputed place among the fathers of the church, and although the turn of his mind was practical rather than speculative, he is known to have taken an energetic part in most of the doctrinal controversies of his time. He was active at the synods of Antioch which investigated and condemned the heresies of Paul, and the rapid spread in Pontus of a Trinitarianism approaching the Nicene type is attributed in large measure to the weight of his influence. Gregory is believed to have died in the reign of Aurelian, about the year 270, though some accounts place his death six years earlier. His festival (semduplex) is observed by the Church of Rome on the 17th of November. For the facts of his biography our earliest and best authority is the *Life* or rather *Panegyric* by Gregory of Nyssa, but there are also incidental notices of him in the writings of Basil the Great. Both these writers represent him as having wrought miracles of a very startling description, but nothing related by them comes near the astounding narratives given in the *Martyrologies*, or even in the *Breviarium Romanum*, in connection with his name.

The principal works of Gregory Thaumaturgus are the *Panegyric* on Origenem (his *ἑποικήν ἑκατονταβιβλίον*), which he wrote when on the point of leaving the school of that great master, a *Melancholia* in *Ecclasticum*, characterized by Jerome as "short but useful", and an *Apologia Constantini*, which treats of the discipline to be undergone by those Christians who under pressure of persecution had relapsed into paganism, but deemed to be restored to the privileges of the church. An *Epiphany Fides*, usually attributed to Gregory, and traditionally alleged to have been recovered by him immediately in vision from the apostle John himself, is of doubtful authenticity. There have been several editions of the works of this father, of these may be mentioned that of Genaid Voss, in Greek and Latin (Mainz, 1804), the Paris edition of 1822, and that contained in the third volume of the *Patrologia* of Paris (Paris, 1788). They are also to be found in a Latin translation in Migne's *Patrologia Graeca*, vol. vii. A separate reprint of the *Panegyricus in Origenem* was published by Bengel in 1722. The *Life* of Gregory has been written by Fulgentius (Rome, 1646) and by Boye (Geneva, 1708).

GREGORY, St., or TOURS (c. 540–594), historian of the Franks, was born at Clermont, Auvergne, not earlier than 539 and not later than 543 A.D. He was the youngest son of Florentius, a provincial senator, and head

of one of the oldest and most powerful Christian families in the country, at his baptism he received the name of George, that of Gregory not having been assumed until his consecration at least thirty years afterwards. He received his education under the superintendence of his uncle Gallus, at that time bishop of Glenineth, and afterwards under Arctus, who succeeded to that see. Having been ordained a deacon on attaining the canonical age, the youthful Georgius Florentinus for a time attended in some ecclesiastical capacity the court of Sigebert of Austrasia, and when in 575 a vacancy occurred in the see of Tours, which had been occupied by many of his kindred, his reputation for piety and wisdom led to his being immediately designated as a suitable successor to that bishopric. Circumstances soon occurred which brought into great prominence his peculiar fitness for this post, first in 575, when Gannan had taken refuge from Chilperic in the sanctuary of St Martin, and afterwards in 577, when Proterstus of Rouen had been unjustly condemned by the rest of his brethren. The firmness and courage which he showed on these and other occasions brought upon him the bitter hostility of the strong minded Queen Fredegond, who caused him to be summoned before a council at Dinan on a charge of treason, of which, however, he was acquitted. In 581 he took a leading part in adjusting that arrangement between Chilperic and Childeric which gave peace to France for many years. During the later years of his life he used his political influence and prestige, which were now immense, with singular usefulness and judgment in the interest alike of his diocese and of the whole country. He died at Tours on the 17th of November 594, and subsequently attained the honours of beatification and canonization, his day in the calendar (seemduple) being November 17th.

Of his writings, he leaves the *Historia Francorum* in ten books, a poem a treatise *De Miraculis* in seven books, a collection of the miracles of Christ and his apostles, those of St Martin, and also of others. Other treatises which he mentions have perished. The *De Miraculis* appears to have occupied him at intervals during the whole of his episcopacy, of the *Historia Francorum* he supposed to have written a few years about the middle of the fifth book by 577, the eighth book was completed before 585, and the tenth about 591, the epilogue being of still later date. This work, which gives Gregory of Tours a just title to be called the father of French history, has no pretensions to elegance or even grammatical accuracy of style, it is wholly unartificial, and betrays in every page the prejudice and ignorance of the age to which it belongs. But it is honestly and faithfully written from the point of view of one whose ardent intention was to trace "the wars of kings with hostile nations, of martyrs with pagans, of churches with heretics," and it is an original source for the period of 174 years which it covers, it is still, notwithstanding the unfavorable judgment which Gibbon has expressed, invaluable.

The edition of the works of Gregory of Tours, which appeared at Paris in 1611-12, has been entirely superseded by that of Rome (Paris, 1699). It includes the not very valuable life of the saint by Odo. The first volume of Migne's *Patrologia* adds to a reprint of Ruffinus an *Historia Septem Dominorum* which is sometimes (but improperly) attributed to Gregory. Translations by Bonnet, Guizot, and others into French have been frequently republished, a German version appeared at Würzburg in 1847-49, it was followed by Cheshevskitch in 1851. See Kiese, *De Greg. Tur. opus vita et scriptis* (Hrslut, in 1860), Lepell, *Gregor v. Tours u. seine Zeit* (Breslau, 1889), St. de Lepsne (Lyon, 1890), and an article in the *Memoirs de l'Académie*, t. xxvii.

GREGORY, the name of a Scottish family, many members of which attained high eminence in various departments of science, sixteen having held professorships. Of the most distinguished of their number a notice is given below.

I DAVID GREGORY (1628-1720), eldest son of the Rev John Gregory of Drumock, Aberdeenshire, was born in 1628. For some time he was connected with a mercantile house in Holland, but on succeeding to the family estate of Kininzie he returned to Scotland, and occupied most of his time in scientific pursuits, freely giving his poorer neighbours the benefit of his medical skill. He is said to have been the first possessor of a barometer in the north of

Scotland, and on account of his success by means of it in producing changes in the weather, he was accused of witchcraft before the presbytery of Aberdeen, but he succeeded in convincing that body of his innocence. He died in 1720.

II JAMES GREGORY (1658-1675), the author of important discoveries in mathematics and optics, younger brother of the preceding, was born in 1658. He was educated at the grammar school of Aberdeen and at Marischal College of that city. At an early period he manifested a strong inclination and capacity for mathematics and kindred sciences, and before completing his twenty-third year he published his famous treatise *Optica Promota*, in which he made known his great invention the Gregorian reflecting telescope. About 1685 he went to the university of Padua, where he studied for some years, and in 1687 published *Opera Geometrica et Hyperbolica Quadratura*, in which he propounded his method of an infinitely converging series for the areas of the circle and hyperbola. In the following year he published also at Padua *Geometria Pars Universalis*, in which he laid down a series of rules for the transmutation of curves and the measurement of their solids of revolution. On his return to England in this year he was elected a member of the Royal Society, in the following year he became professor of mathematics in the university of St Andrews, and in 1674 he was transferred to the chair of mathematics in Edinburgh. In October 1675, while showing the satellites of the planet Jupiter to some of his students through one of his telescopes, he was suddenly struck with blindness, and he died a few days afterwards at the early age of thirty-seven.

Besides the works already mentioned Gregory is the author of *Essai de la Géométrie* (Geneva, 1686, and his twenty-third year), and a treatise *The Great and New Art of Perspective* (Vandy, intended to ridicule certain fallacies of a contemporary writer on this subject, and published at Glasgow in 1672, professedly by "Patrick M'Clure, scholar of the university of St Andrews").

III DAVID GREGORY (1661-1708), nephew of the preceding and son of the David Gregory above mentioned, was born in Aberdeen in 1661. He was educated partly in his native city and partly in Edinburgh, where at the age of twenty-three he became professor of mathematics. In 1691 he was appointed Savilian professor of astronomy at Oxford, an office which he held till his death in 1708. His principal works are *Exercitationes Geometricae de dimensionibus figurarum* (1684), *Catoptrics et Dioptrics Sphaerice Elementaria* (1695), and *Actiometria Physico et Geometrica Elementaria* (1702), the last a work long esteemed by Newton, of whose system it is an illustration and a defence. *A Treatise on Practical Geometry* which he left in manuscript was translated from the Latin and published in 1715. He was succeeded in the chair of mathematics in Edinburgh by his brother James, another brother, Charles, was in 1707 appointed professor of mathematics in the university of St Andrews, and his eldest son, David, became professor of modern history at Oxford, and canon and latterly dean of Christ Church.

IV JOHN GREGORY (1734-1778), professor of medicine in the university of Edinburgh, grandson of James Gregory, the inventor of the Gregorian telescope, and youngest son of Dr James Gregory, professor of medicine in King's College, Aberdeen, was born at Aberdeen, June 3, 1734. After studying at the grammar school of Aberdeen, and completing his literary course at King's College in that city, he attended the medical classes at Edinburgh university. In 1745 he went to Leyden to complete his medical studies, and during his stay there he received without solicitation the degree of doctor of medicine from King's College, Aberdeen. On his return from Holland he was elected professor of philosophy at King's College, but in 1749 he resigned his professorship on account of his duties interfering too much with his practice as a physician. In 1754 he proceeded to

London, where he made the acquaintance of many persons of distinction, and the same year was chosen fellow of the Royal Society. On the death in November 1755 of his brother Dr James Gregory, who had succeeded his father as professor of medicine in King's College, Aberdeen, he was appointed to that office. In 1764 he removed to Edinburgh in the hope of obtaining a more extended field of practice as a physician, and in 1766 he was appointed professor of the practice of physic in the university of Edinburgh, to whose eminence as a medical school he largely contributed. From his eighteenth year Dr Gregory had been subject at irregular intervals to attacks of gout, and on the morning of February 10th, 1773, he was found dead in bed apparently from the results of this disease.

He is the author of *A Comparative View of the State and Faculties of Man with those of the Animal World*, 1765, *Observations on the Duties, Offices, and Qualifications of a Physician*, 1772, *Elements of the Practice of Physic*, 1779, and *A Father's Legacy to his Daughter*, 1774. His *Whole Works*, with a life by Mr Tait (afterwards Lord Woodhouselee), was published at Edinburgh in 1788.

V JAMES GREGORY (1753-1821), professor of the practice of medicine in the university of Edinburgh, eldest son of the preceding, was born at Aberdeen in 1753, and received there the rudiments of his education. He accompanied his father to Edinburgh in 1764, and after going through the usual course of literary studies at that university, he was for a short time a student at Christ Church, Oxford. It was there probably that he acquired that taste for classical learning which afterwards distinguished him. He then entered on the study of medicine at Edinburgh, and, after graduating doctor of medicine in 1774, spent the greater part of the next two years in Holland, France, and Italy. Shortly after his return to Scotland he was appointed in 1776 to the chair his father had formerly held, and in the following year he also entered on the duties of teacher of clinical medicine in the Royal Infirmary. On the illness of Dr Cullen in 1789 he was appointed joint-professor of the practice of medicine, he became sole professor on the death of Dr Cullen in the same year, and he continued to deliver lectures on that subject, to audiences almost regularly increasing, until his last illness in 1821. He died on the 2d April of that year. As a medical practitioner Dr Gregory was for the last ten years of his life decidedly at the head of the profession in Scotland, and as a professor his quickness and commanding energy of intellect, his power of perspicuous and elegant exposition, and his genuine sense of humour gave him a remarkable ascendancy over the minds of his pupils.

Besides his *Compendious Medicine Theoretica*, published in 1788 as a text-book for his lectures on the materia, Dr Gregory was the author of "*A Theory of the Moods of Yellin*," published in the *Edin Phil Trans*, 1787, and of *Lectures on Anatomical and Physiological Essays*, published in two volumes in 1792.

VI WILLIAM GREGORY (1803-1858), son of the preceding, was born 25th December 1803. In 1837 he became professor of chemistry at the Andersonian Institution, Glasgow, in 1839 at King's College, Aberdeen, and in 1844 at Edinburgh University. He died April 24, 1858. Gregory was one of the first in England to advocate the theories of Liebig, and translated several of his works. He is also the author of *Outlines of Chemistry*, 1845, and an *Elementary Treatise on Chemistry* reprinted from the *Encyclopædia Britannica*, 1856.

VII DUNCAN FARQUHARSON GREGORY (1813-1844), brother of the preceding, was born 18th April 1813. After studying at the university of Edinburgh he in 1835 entered Trinity College, Cambridge, where he was for a time assistant professor of chemistry, and was one of the founders of the chemical society. He latterly devoted his chief attention to mathematics, in which he made some important discoveries. He died 23d February 1844.

The *Cambridge Mathematical Journal* was originated, and for some time edited, by Gregory, and he also published a *Collection of Examples of Processes in the Differential and Integral Calculus*, 1811. A *Treatise on the Application of Analysis to Solid Geometry*, which he left unfinished, was compiled by W. Walton, and published posthumously in 1846. His *Mathematical Writings*, edited by W. Walton, with a biographical memoir by Robert L. Ellis, appeared in 1866.

GREGORY, OLIVIERUS, LL.D. (1771-1841), was born 29th January 1774 at Yaxley, in Huntingdonshire. He was only nineteen when he published *Lessons Astronomical and Philosophical* (1793), and soon after, by a manuscript on the "Use of the Sliding Rule," he was fortunate enough to excite the interest of Dr Hutton, professor of mathematics at the Royal Military Academy of Woolwich. Having settled at Cambridge in 1798, Gregory first acted as subeditor of a provincial newspaper, and then opened a bookseller's shop, but before long he found that he would be better off as a private teacher of mathematics. In 1803 he obtained an appointment as mathematical master at Woolwich through the influence of Hutton, and when Hutton resigned in 1807, Gregory succeeded him in the professorship. Failing health obliged him to retire in 1838, and he died at Woolwich 24 February 1841.

Of Gregory's numerous mathematical works it is enough to mention *Elements of the Use of Teachers of Elementary Mathematics* (1840, new edition, 1858), and *Mathematics for Practical Men* (1825), which was revised and enlarged by Henry Low in 1848, and again by J. R. Young in 1862. *His Letters on the Extent of Christianity* (1815) have been several times reprinted, and an abridgement was published by the Religious Tract Society in 1833. He will probably be longest remembered for his *Biography of Robert Wall*, which he appeared in the collection of the *Religious Tract Society* was published separately in 1838, and has since passed through several editions. The minor importance of his *Memoirs of John Mason Good* (1825) is due to the brevity of the subject. Gregory was one of the founders of the Royal Astronomical Society. In 1802 he was appointed editor of the *Gentleman's Diary*, and in 1818 editor of the *Ladies' Diary* and superintendent of the finances of the Stationers' Company.

GREIFENBERG, the chief town of a circle in the Prussian province of Pomerania and government of Stettin, is situated on the Rega, 46 miles N.E. of Stettin. It possesses a royal gymnasium and a higher girls' school. Agriculture, linen-weaving, and the manufacture of stores are the principal industries. Greifenberg possessed town rights as early as 1203, and in the 14th and 16th centuries had a considerable shipping trade, but lost much of its prosperity during the Thirty Years' War. Including the garrison, the population in 1875 was 5681. See Riemann, *Geschichte der Stadt Greifenberg in Pommern*, 1862.

GREIFENHAGEN, the chief town of a circle in the Prussian province of Pomerania and government of Stettin, is situated on the Regitz, 12 miles S.S.W. of Stettin. Its prosperity depends chiefly on agriculture, and it has a considerable cattle trade. There are also linen manufactories and saw-mills. Greifenhagen was built in 1230, and was raised to the rank of a town and fortified in 1262. In the Thirty Years' War it was taken both by the imperialists and the Swedes, and in 1675 it was captured by the Brandenburgers, into whose possession it came finally in 1679. The population in 1875 was 6759.

GREIFSWALD, or GREIFSWALDE, the chief town of a circle in the Prussian provinces of Pomerania and government of Stralsund, is situated on the Ryck, 3 miles from its mouth in the Baltic, and 20 miles S. by E. of Stralsund. It has wide and regular streets, and is surrounded by promenades formed out of the old ramparts. It is the seat of a court of appeal for the government district of Stralsund. The university, founded in 1456, is attended by nearly 500 students, about one-half of whom belong to the medical faculty, connected with it are an anatomical theatre, an infirmary, a chemical laboratory, a pathological institute, and a library containing nearly 140,000 volumes. The

principal other buildings are the church of St Nicholas (with a tower 330 feet high and a valuable library), the old town house, the theatre, the gymnasium, the orphanage, and the lunatic asylum. There is a considerable shipping trade in Pomorany coin with England, France, and the Mediterranean ports. Fish-curing, shipbuilding, and the manufacture of machines, railway waggons, needles, soap, tobacco, and oil, are the principal other industries. The population in 1873 was 18,023.

Greifswald was founded about 1210 by mechanics and merchants from the Netherland. In 1280 it received a town constitution and in 1300 it was raised to the rank of a city. In 1300 it was taken by the Danes. In 1309 it formed a league with the Illustrious towns, Stralsund, Rostock, Wismar, and Lübeck, and it took part in the wars which they carried on against the king of Denmark and Norway. During the Thirty Years War it was divided into 5 fortresses by the imperialists, but they vacated it in 1631 to the Swedes, in whose possession it remained until the peace of Westphalia. In 1678 it was captured by the elector of Brandenburg, but it was restored to the Swedes in 1715 following 30 years, in 1718 it was desolated by the Russians, in 1718 it came into the possession of Denmark, and in 1721 it was again restored to Sweden, under whose protection it remained till 1815, which, along with the whole of Swedish Pomerania, it came into the possession of Prussia. See *Koenigstein, Geschichte des Universitäts-Greifswald*, 1866, and *Ortshandlung, Beitrag zur Geschichte des Stadt-Greifswald*, 6 vols., 1897-98.

GREIZ, or GERITZ (formerly *Greunds on Greus*), a town of Germany, capital of the principality of Reuss Greiz, is situated in a pleasant valley on the right bank of the White Elster, near the borders of Saxony, and 14 miles W by S of Zwickau. It is surrounded by walls, and is tolerably well built. The principal buildings are the prince's palace surrounded by a fine park, the old "residence" castle on a rock overlooking the town, the summer palace with a fine garden, the old town church dating from 1225 and possessing a beautiful tower, the town house, the city school buildings, the normal seminary for the principality, and the lower city school. The industries include dyeing, tanning, and the manufacture of woollen, cotton, and silk cloth, shawls, cowls, and paper. The population in 1875 was 12,867.

Greiz is apparently of Slavic origin. From the 12th century it was governed by bishops, but in 1286 it came into the possession of Gera, and in 1509 of the younger line of the house of Plauen. It was wholly destroyed by fire in 1494, and almost wholly in 1602. See *Wille, Greiz and seine Umgebung*, 1876.

GRENNADA, the most southern island of the Antilles, lies between 11° 58' and 12° 30' N lat and 61° 20' and 61° 35' W long. It is 30 leagues S W of Barbados, and about 60 miles from the nearest point of South America. Its length from north to south is about 24 miles, and its greatest breadth is 12 miles. The area is 138 square miles.

Grenada is rendered highly picturesque by ridges of hills covered with trees and bushwood, and by an irregular but continuous range of mountains which traverses the island from north to south, in some parts rising to 3000 feet above the level of the sea. Lesser ridges branch off forming rich and picturesque valleys. The mountains and some parts of the lowlands consist of red and gray sandstone, gneiss, and hornblende, and argillaceous schist. The strata are much diversified and irregular. Sulphur and fuller's earth are found. Porphyry, limestone, and basaltic rocks occur at certain places. Rivers are numerous, but not large. In the centre of the island, 1740 feet above the level of the sea, is the Grand Etang, a circular lake 2 miles in circumference and 14 feet deep, feeding numerous small rivers. Lake Antoine is another remarkable natural feature. There are several hot chalybeate and sulphurous springs. Along the coast are numerous excellent bays and harbours. The trees abound with fish, game, and birds of various species are found. Hurricanes are comparatively infrequent, but earthquake shocks are sometimes experienced. The average temperature is 82° Fahr., but the higher parts are cooler. Considerable rain falls. The

soil is extraordinarily fertile, but cotton, indigo, and tobacco are not now cultivated. Fruits and some kinds of European vegetables grow luxuriantly. Sugar cultivation is not extending, but cocoa is now making rapid strides. The island is divided into six parishes. Formerly it had a house of assembly, but is now a crown colony under the general government of the Windward Islands. It has a lieutenant governor and a council consisting of officials and members nominated by the crown.

The capital, St George's (population about 5000), is built upon a peninsula projecting into a spacious bay on the west side of the island, near the southern extremity. The houses are of brick or stone, and stand on high ground which rises from the bay. The town is divided by a ridge running into the sea, forming on one side the caserne, a large basin of water, where ships lie landlocked, close to wharves and stores. A saluting battery, Fort George, overlooks the entrance. On the left, the land rises to the fortifications of Hospital Hill, and a long ridge connects this fort with Richmond Heights, which form the background of the scene and are also fortified. The ridge which connects Fort George with Hospital Hill separates the caserne from the larger portion of the town, which contains an extensive market-place, and leads up to a walled castle. Besides the caserne, there is a spacious sheet of water called the lagoon, separated from the former by a reef passable only by boats.

Between Grenada and St Vincent there are several small islands called Grenadines, some being included in the government of Grenada. Of these Carriacou is the most important. It is about 19 miles in circumference, and contains 3071 inhabitants. Ground provisions, live stock, and some cocoa are cultivated.

The exports in 1877 were—cocoa, 1544 tons, value, 6720 galls., value, 53,009 galls., sugar, 2792 tons. The cocoa exports in 1878 were 1800 tons, an amount considerably exceeded in 1879. The total value of imports amounted in 1877 to £127,204, including £60,201 from the United Kingdom, and £46,724 from the British West Indies. The value of exports to the United Kingdom was £193,821, and for other countries, £28,085—total, £215,906. The revenue was £229,084, of which customs produced £13,460, and the expenditure was £28,581. Population (1877), 41,256. About 400 Coolie immigrants were introduced in 1877. Considerable immigration takes place from Barbados. The legislature grants £2000 annually for education, distributed among 30 schools, 6 English, 5 Wesleyan, 9 Roman Catholic, with 2908 scholars.

Grenada was discovered by Columbus in 1498. The Spaniards, however, did not form a settlement. The island was ceded to the "Caribbees" granted to the earl of Carlisle in 1627, but it was inhabited only by warlike Caribs until 1650-51, when Du Puy, governor of Martinique, organized two expeditions to it. The Frenchmen were at first well received by the natives, but great cruelty was exercised in the extirpation of the latter. The island made little progress until about 1700. In 1714 the French West India Company acquired their property in Grenada, commercial intercourse began to grow up with Martinique, and when the company was dissolved the island became vested in the crown of France. In 1763 it contained 1262 whites, 11,991 slaves, and 88 sugar plantations. In 1763 Grenada capitulated to the British forces, and it was formally ceded in the treaty of peace of 1763. It was, however, retaken by the French in 1779, and not finally restored to Great Britain in 1783 till the general peace.

GRENOBLE, a fortified city of France, formerly the chief town of Dauphiné and now of the department of the Isère, lies 58 miles E of Lyons, in 45° 11' 67" N lat and 5° 43' 29" E long. Few of the cities of France have a finer situation. The Isère unites with the Drac a few miles further down, and the broad and fertile valley through which the rivers flow is unobscured by a fine panorama of hills and mountains. From the bottom of the gorge, for example, the eastward view comprises the Savoie Alps, with the summit of Mount Blanc, and the westward the mountains of St Nizier, while more to the north the hills rise directly above the town, and are crowned by the fort of the Bastille. The beauty of the Isère itself is enhanced by fine bridges

and quays. With the exception of its more modern portions, the town of Grenoble is characterized by the tortuous and crowded streets usual in places that have long been confined within strong fortifications. The cathedral of Notre Dame, a vast brick building of various periods from the 10th to the 17th century, the foundation of which is traditionally ascribed to Charles the Great, the church of St Laurence, with a remarkable crypt of the 11th century, long believed to be an old temple of Esculapius, and the church of St André, founded by the dauphin Guignes André about 1280, and subsequently visited for the sake of the tomb of Bayard, removed thither in 1822, are the most noteworthy of the ecclesiastical edifices. The palace de justice is a striking erection of the 15th and 16th centuries occupying the site of the old castle of the dauphins, and in front is a statue of Bayard dating from 1823. The old town-hall has nothing remarkable about it, but the new prefecture, built at a cost of 1,404,000 francs about 1867, is a handsome structure. Besides its university or academy, with the three faculties of law, science, and literature,

Grenoble possesses a lyceum, an episcopal seminary, a school of artillery of the first class, two normal schools, and a great variety of special educational institutions. The library, which since 1808 has been located along with the museum in a building which cost more than 1,500,000 francs, is a noble collection of upwards of 178,875 volumes, on which the town has expended 2,000,000 francs.¹ Among the numerous societies of Grenoble it is enough to mention the *Académie delphinale* (1772), the statistical society, the society of the friends of the arts, the society of agriculture, and the zoological society of the Alps, which maintains zoological gardens. At the head of the benevolent institutions is the general hospital, originally founded by Amon Chisey in 1424, and now comprising civil and military departments, an orphanage, and an asylum for the aged and infirm. It was in Grenoble that the first mutual benefit society was founded in 1803, and the number of such associations in the town was upwards of 40 about 1870. In 1836 M. Berrist Saint Prix established a society for the extinction of mendicancy, and in 1851 M. Frédéric originated

an *association alimentaire* for the purpose of providing the poorer classes with good food at the cheapest possible rate. The staple industry of Grenoble is the making of gloves, 115 establishments, employing 2000 workmen and 20,000 needlewomen in the town and neighbourhood, turn out annually 850,000 dozen pairs. Liqueurs, leather, straw hats, paper, lime, and cement hold a principal place among the miscellaneous products. The population of Grenoble was 26,852 in 1851, 35,280 in 1872, and 43,504 in 1876.

Grenoble occupies the site of Cularo, a village of the Allobroges which first became of importance when it was fortified by Diocletian and Maximian. Its present name is a corruption of Gratianopolis, a title assumed in honour of Gratian, who had strengthened the walls. From the Burgundians who gained possession in 487, a little town passed under the Franks, and on the dismemberment of the empire of Charles the Great it was included in the limits of Cisalpine Burgundy. After the 10th century its bishops grew into power, but they were finally supplanted in the 15th century by the counts of Albon, afterwards known as the Dauphins. Though it was ceded in 1249 to France along with Dauphiné, the city continued to enjoy special privileges. In 1558 it was sacked by the Baron des Adrets, but in 1573 the courtesy of its governor De Gondi saved it from sharing in the massacre of St Bartholomew. Lesdiguières (Raoul de Montagu) took the town by siege in 1590 in name of Henry IV, and he afterwards made his government memorable by his fortifications, quays, and other admirable enterprises. In the close of the 18th century the name of Grenoble appears in the van of the revolutionary movement, the attempt of the Government to substitute a new judicial system for that of the independent provincial parliaments incensed the people to arms and the "day of the tiles" (7th June 1788) is memorable for the defeat of the royal forces. Grenoble was the first town to open its gates to Napoleon on his return from Elba in 1815, but a few months afterwards it was obliged to surrender to the Austrians. Owing to its situation Grenoble is subject to inundations, in 1219 it was almost swept away, and from that date to 1868 no fewer than 15 similar disasters are enumerated. The great flood of 1773 is known as the "Deluge de la Saint-Georges." In 1869 the walls were 3 feet deep throughout the town. Among the celebrated natives of Grenoble are Vaucanson, Mably, Condillio, Boyle (Stendhal), Bonnavo, and Camus Fellen. See Champollion-Figeac, *Antiquité de Grenoble*, (Grenoble, 1807), Pictet, *Hist. de Grenoble et de ses environs* (Grenoble, 1859).

GRENVILLE, GEORGE (1712-1770), an English statesman, second son of Richard Grenville and Hester Temple, afterwards Countess Temple, was born October 14th, 1712. He was educated at Eton and at Christ Church, Oxford, and in his twenty-fifth year was called to the bar. The habits of industry, the technical knowledge, and the intellectual discipline which he acquired in connection with his legal training were of great advantage to him in his political career, and for a considerable period he amply compensated for the absence of every natural gift except inexhaustible fluency, and of all but the merest rudimentary qualities of statesmanship. He entered Parliament in 1741 as member for Buckingham, and continued to represent that borough till his death in 1770. In December 1744 he became a lord of the admiralty, in June 1747 a lord of the treasury, and in 1754 treasurer of the navy and privy councillor. He remained in office in 1761, when his brother Lord Temple and his brother-in-law Pitt resigned upon the question of the war with Spain, and in the administration of Lord Bute he was entrusted with the leadership of the House of Commons. In May 1763 he was appointed secretary of state, and in October first lord of the admiralty, and in April 1763 he became first lord of the treasury and chancellor of the exchequer. The most prominent measures of his administration were the prosecution of Wilkes and the passing of the American Stamp Act, which led to the first symptoms of alienation between America and the mother country. During the latter period of his term of office he was on a very unsatisfactory footing with the young king George III., who gradually came to feel a kind of horror of the interminable persistency of his conversation, and whom he endeavoured to make use of as the mere puppet of the ministry. The king made

¹ See Garnier, *La Bibliothèque de Grenoble, 1772-1878*, Paris, 1878.

various attempts to induce Pitt to come to his rescue by forming a ministry, but without success, and at last had recourse to the marquis of Rockingham, on whose agreeing to accept office Grenville was dismissed July 1765. He never again held office, and died 13th November 1770. In 1749 he was married to Elizabeth, daughter of Sir William Wyndham, by whom he had a large family. His son, the second Earl Temple, was created Marquis, and his grandson Duke, of Buckingham.

A contemptuous application by Pitt to Grenville of the lines "Gentle Shepherd, tell me where," caused him to be dubbed the "gentle shepherd" for the remainder of his life, and this would seem to indicate a deficiency in the personal characteristics which insure any high degree of general respect. Exemplary in the observance of all the decencies of private life, and upright and honourable in all his political relations, he yet possessed none of those attractive or commanding qualities which are sometimes found an advantageous substitute for strict moral integrity, and which the possessor of moral integrity cannot afford to despise. He was moreover under the dominion of an ambition ludicrously out of proportion to his abilities, and the self-confidence with which he pursued his own purposes can be attributed only to the narrow range of his political vision. Though few excelled him in a knowledge of the details of the House or in mastery of administrative details, his tact in dealing with men and with affairs was so defective that there is perhaps no one who has been at the head of an English administration to whom a lower place can be assigned as a statesman. *The Grenville Papers, being the Correspondence of Richard Grenville, Earl Temple, K.G., and the Right Hon. George Grenville, then Friends and Contemporaries*, was published at London in 1852.

GRENVILLE, WILLIAM WYNDHAM GRENVILLE, Lord (1789-1834), English statesman, son of the preceding, was born 25th October 1750. He was educated at Eton and Oxford, and for some time studied at the Inns of Court, but never practised at the bar. In February 1782 he was elected a member of parliament for the county of Buckingham, and in the September following he became secretary to his brother the marquis of Buckingham, who had been named Lord-lieutenant of Ireland. On the overthrow of the cabinet of Lord Shelburne in the following year he returned to England, and in December he was appointed by his cousin Pitt paymaster-general of the forces. In 1789 he was chosen speaker of the House of Commons, but he vacated the chair in the same year, and was transferred to the Upper House with the title of Lord Grenville, on being appointed secretary of state. He exchanged this office in 1791 for that of secretary of foreign affairs, being regarded by Pitt as the person best fitted to carry out his policy in reference to France. Along with Pitt he resigned office in 1801, on account of the king declining to grant any concessions to the Catholics, and when Pitt, on accepting office in 1804, did not stipulate for Catholic emancipation he declined to join his ministry, and entered into a close alliance with Fox. On the death of Pitt in 1806 he became the nominal head of the Government of "All the Talents," whose military projects resulted very unsuccessfully, but which deserves to be remembered with honour on account of the Act for the abolition of the slave trade. Its influence was, however, considerably weakened by the death of Fox, and as the king in March 1807 demanded from Grenville an assurance that he would initiate no measures for the relief of the Catholics, and his colleagues found it necessary to resign. His colleagues were not unanimous in approving of his conscientiousness, and Sheridan expressed the opinion of more than himself when he remarked, "I have known many men knock their heads against a wall, but I never before heard of a man collecting bricks

and building a wall for the express purpose of knocking out his own brains against it." Lord Grenville never again held office. He continued to be one of the principal supporters of Catholic emancipation, and during the remainder of his political career generally voted with the Whigs, although in 1815 he separated himself from Lord Grey and supported the wailike policy of Lord Liverpool. In 1819, when the marquis of Lansdowne brought forward his motion for an inquiry into the cause of the distress and discontent in the manufacturing districts, Grenville delivered an earnest speech in which he advocated the adoption of severely repressive measures. He died at his residence, Dropmore, Buckinghamshire, 12th January 1834.

Though the talents of Lord Grenville were not of a high order, his straightforwardness, great industry, political knowledge, firmness of mind, and moderate opinions secured him considerable political influence. He can also lay claim to be enrolled among those English statesmen who have distinguished themselves in literature. Besides editing the letters of the earl of Chatham to his nephew Thomas Pitt, afterwards Lord Camelford, he printed for private circulation an edition of Homer with annotations, and also a small volume entitled *Myra Mirror*, consisting of translations into Latin from Greek, English, and Italian. In 1800 he was chosen chancellor of the university of Oxford. He married in 1792 Anne Pitt, daughter of Lord Camelford, but had no issue, and the title became extinct.

GRESHAM, SIR THOMAS (1519-1579), a London merchant, the founder of the Royal Exchange and of Gresham College, London, was born in 1519. Descended from an old Norfolk family, he was the only son of Sir Richard Gresham, a leading London merchant, who for some time held the office of lord mayor and for his services as agent of Henry VIII in negotiating loans with foreign merchants received the honour of knighthood. Though his father intended him to follow his own profession, he nevertheless sent him for some time to Cambr College, Cambridge, but there is no information as to the duration of his residence. It is uncertain also whether it was before or after this that he was apprenticed to his uncle Sir John Gresham, who was also a merchant, but we have his own testimony that he served an apprenticeship of eight years. In 1543 at the age of twenty-four he was admitted a member of the Mercers' Company, and in the same year he went to the Low Countries, where, either on his own account or on that of his father or uncle, he both carried on business as a merchant and acted in various matters as an agent for Henry VIII. In 1544 he married the widow of William Read, a London merchant, but he still continued to reside principally in the Low Countries, having his headquarters at Antwerp. When in 1551 the mismanagement of Sir William Danell, "king's merchant" in the Low Countries, had brought the English Government into great financial embarrassment, Gresham was called in to give his advice, and chosen to carry out his own proposals. Then leading feature was the adoption of various methods—highly ingenious, but quite arbitrary and unfair—for raising the value of the pound sterling on the "bourse" of Antwerp, and it was so successful that in a few years nearly all King Edward's debts were discharged. The advice of Gresham was likewise sought by the Government in all their money difficulties, and he was also frequently employed in various diplomatic missions. He had no stated salary, but in reward of his services received from Edward various grants of the annual value of which at that time was ultimately about £400 a year. On the accession of Mary the council resolved on his recall, but before the letter was sent they changed their opinion, and as he professed his zealous desire to serve the queen, and manifested great adroitness both in negoti-

ating loans and in smuggling money, arms, and foreign goods, not only were his services retained throughout her reign, but besides his salary of twenty shillings *per diem* he received grants of church lands to the yearly value of £200. Under Queen Elizabeth, besides continuing to act as financial agent of the crown, he was for some time ambassador at the court of the duchess of Parma. In 1559 he received the honour of knighthood. By the outbreak of the war in the Low Countries he was compelled to leave Antwerp on the 19th March 1567, but, though he spent the remainder of his life in London, he continued his business as merchant and financial agent of the Government in much the same way as formerly. Elizabeth also found him useful in a great variety of other ways, among which was that of acting as jailer to Lady Mary Grey, who, as a punishment for marrying Thomas Keys the sergeant poet, remained a prisoner in his house from June 1569 to the end of 1572. In 1565 Gresham made a proposal to the court of aldermen of London to build at his own expense a house or exchange, on condition that they purchased for this purpose a piece of suitable ground. In this proposal he seems to have had an eye to his own interest as well as to the general good of the merchants, for by a yearly rental of £700 obtained for the shops in the upper part of the building he received a sufficient return for his trouble and expense. Gresham died suddenly, apparently of apoplexy, 21st November 1579. His only son predeceased him, and his illegitimate daughter, Anne he married to Sir Nicolas Bacon, brother of the great Lord Bacon. With the exception of a number of small sums bequeathed to the support of various charities, the bulk of his property, consisting of estates in various parts of England of the annual value of more than £2300, was bequeathed to his widow and her heirs with the stipulation that after her decease his residences in Bishopsgate Street, as well as the rents arising from the Royal Exchange, should be vested in the hands of the corporation of London and the Mercers' Company, for the purpose of instituting a college in which seven professors should read lectures—one each day of the week—on astronomy, geometry, physics, law, divinity, rhetoric, and music. The lectures were begun in 1597, and were delivered in the original building until 1763, when, on the ground that the trustees were losers by the gift, it was made over to the crown for a yearly rent of £500, and converted into an excise office. From that time a room in the Royal Exchange was used for the lectures until in 1843 the present building was erected at a cost of £7000. It contains a large library, professors' rooms, and a theatre capable of holding 600 persons.

A notice of Gresham is contained in Fuller's *Worthies* and Wallis's *Gresham Professors*, but the fullest account of him, as well as of the history of the Exchange and Gresham College is that by J. M. Bagen in his *Life and Times of Sir Thomas Gresham*, 2 vols., 1839. See also a *Brief Memoir of Sir Thomas Gresham*, 1838, and *The Life of Sir Thomas Gresham, Founder of the Royal Exchange*, 1846.

GRESSET, JEAN BAPTISTE (1709-1777). The literary history of Gresset might be dismissed with the simple statement that he wrote *Vent Vent*. By that one poem he is remembered. His life is, however, interesting from another fact, that he, who almost alone among French poets wrote nothing of which a moralist need be ashamed, spent the last twenty-five years of his life in regretting the frivolity which enabled him to produce the most charming of poems. He was born at Amiens, and brought up by the Jesuits of that place. As a boy he displayed such great promise that, according to the usual custom of the society, the fathers resolved to receive him among themselves. He was accepted as a novice at the age of sixteen, and sent to pursue his studies at the Collège Louis le Grand in Paris. After completing his course he was appointed, being then under twenty years of age, to a post as professor or assistant master

in a college at Rouen. It was, it must be remembered, a son of the society of Jesus, as such he had been drilled and disciplined to perfect obedience, in every point except that of orders he was an ecclesiastic. Probably it was not the intention of the society that he should become a priest. They reckoned upon his continuing a lay brother, and helping the cause by his position as a teacher. From such a mind so trained, so taught to regard everything from the priestly point of view, devoted to the most severe studies, occupied in the grave and responsible work of teaching, what literary fruit was to be expected? Perhaps a treatise on a Greek particle, an essay on Latin style, a grammatical or anything but that which really appalled—the then, graceful, pleasant poem by which he will ever be remembered. He published *Vent Vent* at Rouen, being then twenty-four years of age. It is a story, in itself exceedingly humorous, showing how a parrot, the delight of a convent, whose talk was all of prayers and pious ejaculations, was conveyed to another convent as a visitor to please the nuns. On the way he falls among bad companions, forgets his convent language, and shocks the sisters on arrival by profane swearing. He is sent back in disgrace, punished by solitude and plain bread, presently repents, reforms, and is killed by kindness. The story, however, is nothing. The treatment of the subject, the atmosphere which surrounds it, the delivery in which the little patter was given of the nuns, their jealousy, their tiny taunts are presented, taken the reader entirely by surprise. The poem stands absolutely unvarnished, even among French *contes en vers*.

Gresset found himself famous. He left Rouen, went up to Paris, where he found refuge in the same garret which had sheltered him when a boy at the Collège Louis le Grand, and there wrote his second poem, *Ma Chantreuse*. Then trouble came upon him, complaints were made to the fathers of the alleged licentiousness of verses which were as innocent as any school-boy's novel, the real cause of complaint being the ridicule which *Vent Vent* seemed to throw upon the whole race of nuns. An example, it was urged, must be made. Gresset was expelled the order. Men of robust mind would have been glad to get rid of such a yoke. Gresset, who had never been taught to stand alone, went forth weeping. He became a man of letters, he wrote many other poems, none of which made any mark. He never in fact attained the same level as *Vent Vent*. He wrote two or three comedies. One, called *Le Méchant*, still keeps the stage, though it is difficult to assign it much merit. He was admitted to the Académie. And then, still young, he retired to Amiens, where he fell into the hands of the priests, and became their abject slave. His brief escape from the discipline of the church became the subject of the deepest remorse. He repented of his poems, and even went so far as to address to the bishop an abjuration of his title of dramatist, and to implore pardon of the Virgin for having written plays. The history of French literature presents many examples of poets in old age repenting the sins of their youth, the example of Gresset is unique as beginning, while in full manhood, a sincere repentance for having even in so pleasant and innocent a way brought into ridicule the institutions of the church.

GRÉTRY, ANDRÉ-ÉTIENNE MONESTRÉS (1741-1813), a celebrated composer of French opera, was born at Liège, February 11, 1741. He received his first musical education in the *matinée* of the college of St Denis, where his father, a poor musician, occasionally acted as violinist. Leclerc and Reinken were his early masters. But of greater importance was the practical tuition he received by attending the performance of an Italian opera company. Here he heard the operas of Galuppi, Pergolesi, and other masters, and the desire of completing his own studies in Italy was the immediate result. To find the necessary

means he composed in 1759 a mass which he dedicated to the canons of the Liège cathedral, who in return sent him to the Collège de Liège at Rome, founded by a citizen of Liège for the benefit of his townsmen studying in Rome. Here Grétry resided for five years, studiously employed in completing his musical education under Casali. His proficiency in harmony and counterpoint was, however, according to his own confession, at all times very moderate. Neither was any deep scholarship required for the style of composition to which he soon exclusively devoted himself. His first great success was achieved by an Italian intermezzo or opéraetta, *Le vendémiaire*, composed for the Albertini theatre in Rome, and received with universal applause. It is said that the study of the score of one of Monvigny's operas, lent to him by a secretary of the French embassy in Rome, decided Grétry to devote himself to French comic opera. On New Year's Day 1767 he accordingly left Rome, and after a short stay at Geneva (where he made the acquaintance of Voltaire, and produced another opéraetta) went to Paris. There for two years he had to contend with the difficulties incident to poverty and obscurity. He was, however, not without friends, and by the intercession of one of these, Count Cieszt, the Swedish ambassador, Grétry obtained a libretto from the celebrated Marmontel, which he set to music in less than six weeks, and with, on its performance in August, 1768, met with unparalleled success. The name of the opera was *Le Huron*. Two others, *Lucile* and *Le Tableau Parlant*, soon followed, and thenceforth Grétry's position as the leading composer of comic opera was safely established. Of the fifty operas which embody his musical activity only two or three have survived, and perhaps as many more are worth remembering. His masterpieces are *Zémis et Aro*, and *Richard Cœur de Lion*,—the first produced in 1771, the second in 1784. The latter in an indirect way became connected with a great historic event. In it occurs the celebrated romance, *O Richard, ô mon roi, l'univers s'abandonne*, which was sung at the banquet—"fatal as that of Thyestes," remarks Carlyle—given by the bodyguard to the officers of the Versailles garrison on October 3, 1789. The *Mai sans laus* not long afterwards became the reply of the people to the expression of loyalty borrowed from Grétry's opera. The composer himself was not unimpressed by the great events he witnessed, and the titles of some of his operas, such as *La Raison et Républicaine* and *La Fête de la Raison*, sufficiently indicate the epoch to which they belong, but they are more *pièces de circonstance*, and the republican enthusiasm displayed is not genuine. Little more successful was Grétry in his dealings with classical subjects, and none of his operas belonging to that class are worth remembering. His genuine power lies in the delineation of character, and in the expression of tender and typically French sentiment. For the first-named purpose the careful and truly admirable fidelity with which his music is wedded to the words is invaluable. In this respect Grétry's works are indeed representative of French operatic music at its best. The structure of his concerted pieces on the other hand is frequently flimsy, and his instrumentation so feeble that the orchestral parts of some of his works had to be rewritten by other composers, in order to make them acceptable to modern audiences. Of his deficiencies of harmonization Grétry himself was well aware, and his confessions in this respect are strangely at variance with the self-sufficient tone which pervades his literary effusions on musical and even on political and social topics. During the Revolution Grétry lost much of his property, but the successive Governments of France vied in favouring the composer, regardless of political differences. From the old court he received distinctions and rewards of all kinds, the republic made him an inspector of the Conservatoire, Napoleon granted him

the cross of the Legion of Honour and a pension. Grétry died September 24, 1813, at the Hermitage in Montmouley, formerly the house of Rousseau. Fifteen years later his heart was transferred to his birthplace, permission having been obtained after a tedious lawsuit. In 1842 Grétry's colossal statue in bronze was inaugurated at Liège.

GREUZE, JEAN D'APRÈS (1725-1805), in the full tide of the 18th century, when professional distinction appeared to be reserved exclusively for those who devoted themselves to the production of historical or allegorical subjects, achieved an immense reputation as a painter of scenes of domestic life. He was born at Tournus in 1725, and is generally said to have formed his own talent, this is, however, true only in the most limited sense, for at an early age his inclinations, though thwarted by his father, were encouraged by a Lyonsese artist named Grandon or Gondrom who enjoyed during his lifetime considerable reputation as a portrait-painter. Grandon not only persuaded the father of Greuze to give way to his son's wishes, and permit the lad to accompany him as his pupil to Lyons, but when at a later date he himself left Lyons for Paris—where his son-in-law Grétry the celebrated composer enjoyed the height of favour—Grandon carried young Greuze with him. Settled in Paris, Greuze worked from the living model in the school of the Royal Academy, but distinguished himself as a student of his teachers and as a producer of his first pictures, *Le Père de Famille* explaining *la Bible* à ses Enfants, considerable doubt was felt and shown as to his status in its production. By other and more remarkable works of the same class Greuze soon established his claims beyond contest, and won for himself the notice and support of the well-known connoisseur La Live de Jully, the brother-in-law of Madame d'Épinay. In 1755 Greuze exhibited his *Avoué Triomphe*, upon which, presented by Pigalle the sculptor, he was immediately *agréé* by the Academy. Towards the close of the same year he left France for Italy, in company with the Abbé Louis Gougenot, who had deserted from the magistrature,—although he had obtained the post of "conseiller au Châtelet"—in order to take the "petit collet." Gougenot had some acquaintance with the arts, and was highly valued by the Académiciens,—who, during his journey with Greuze elected him an honorary member of their body—on account of his studies in mythology and allegory, his acquirements in these respects are said to have been largely utilized by them, but to Greuze they were of doubtful advantage, and he lost rather than gained by this visit to Italy in Gougenot's company. He had undertaken it probably in order to alienate those who taxed him with ignorance of "great models of style," but the Italian subjects which formed the entirety of his contributions to the Salon of 1757 showed that he had been put on a false track, and he speedily returned to the sources of his first inspiration. In 1759, 1761 (*L'Accordeur de Village*,—*Louville*), and 1763 Greuze exhibited with ever increasing success, in 1765 he reached the zenith of his powers and reputation. In that year he was represented with no less than thirteen works, amongst which may be cited *La Jeune Fille qui pleure son Orseau mort*, *La Bonne Mère*, *Le Mauvais Fils puni* (Louvre), and *La Malédiction Paternelle* (Louvre). The Academy took occasion to press Greuze for his diploma picture, the execution of which had been long delayed, and forbade him to exhibit on their walls until he had complied with their regulations. "J'ai vu la lettre," says Diderot, "qui est un modèle d'honnêteté et d'estime, j'ai vu le réponse de Greuze qui est un modèle de vanité et d'impertinence. Il fallait appuyer cela d'un chef-d'œuvre, et c'est ce que Greuze n'a pas fait." Greuze wanted to be received as an historical painter, and produced a work which he intended to vindicate his right to despoil his qualifications as a *peintre de genre*. This unfortunate canvas,—

Sevres et Chacalla (Louvre).—was exhibited in 1769 side by side with Greuze's portrait of Jeannot (Lovrre), and his admirable Petite Fille au Chien Noir. The Académiciens received their new member with all due honours, but at the close of the ceremonies the Director addressed Greuze in those words—"Monsieur, l'Académie vous a reçu, mais c'est comme peintre de genre, elle a vu égaré à vos annuées productions, qui sont excellentes, et elle a fermé les yeux sur celle-ci, qui n'est digne ni d'elle ni de vous." Greuze, greatly incensed, quailed with his *confidés*, and ceased to exhibit until, in 1804, the Revolution had thrown open the doors of the Academy to all the world. In the following year on 4th March 1805, he died in the Louvre in great poverty. He had been in receipt of considerable wealth, which he had dissipated by extravagance and bad management, so that during his closing years he was forced even to solicit commissions which his enfeebled powers no longer enabled him to carry out with success. The brilliant reputation which Greuze acquired seems to have been due, not to his acquirements as a painter,—for his practice is evidently that current in his own day,—but to the character of the subjects which he treated. That return to nature which inspired Rousseau's attacks upon an artificial civilization demanded expression in art. Diderot in *Le Fils Naturel* et *Le Père de Famille* tried to turn the vein of domestic drama to account on the stage, that which he tried and failed to do, Greuze, in painting, achieved with extraordinary success, although his works, like the plays of Diderot, were affected by that very artificiality against which they protested. The touch of melodramatic exaggeration, however, which runs through them finds an apology in the firm and brilliant play of line, in the freshness and vigour of the flesh tints, in the enticing softness of expression (often obtained by almost an abuse of *mélange*), by the alluring air of health and youth, by the sensuous attractions, in short, with which Greuze invests his lessons of bourgeois morality. As Diderot said of La Bonne Mère, "ça pèche la population," and a certain piquancy of contrast is the result which never fails to obtain admirers. La Jeune Fille à l'Agneau foisted, indeed, at the Fountains sale in 1855 no more than 1,000,200 francs. One of Greuze's pupils, Mademoiselle Le Doux, imitated with success the manner of her master, his daughter and granddaughter, Madame de Valory, also inherited some traditions of his talent. Madame de Valory published in 1813 a Comédie-vau-deville, *Greuze, ou l'Accordée du Village*, to which she prefixed a notice of her grandfather's life and works, and the *Salons* of Diderot also contain, besides many other particulars, the story at full length of Greuze's quarrel with the Academy. Four of the most distinguished engravers of that date, Messieurs Philippe, Flupart, Gaillard, and Levesseur, were specially entrusted by Greuze with the reproduction of his subjects, but there are also excellent prints by other engravers, notably by Carré and Le Bas. (N. P. S. P.)

GREVILLE, CHARLES CAVENDISH FULKE (1794-1865), a great grandson by his father of the fifth earl of Warwick, and son of Lady Charlotte Bentinck, daughter of the duke of Portland, formerly a leader of the Whig party, and first minister of the crown. Greville was born 3d April 1794. Much of his childhood was spent at his grandfather's house at Bulstrode. He was one of the pages of George III., and was educated at Eton and Christ Church, Oxford, but he left the university early, having been appointed private secretary to Earl Bathurst before he was twenty. The interest of the duke of Portland had secured for him the secretaryship of the island of Jamaica, which was a sinecure office, the duties being performed by a deputy, and the reversion of the clerkship of the council. Greville entered upon the discharge of the duties of clerk of the council in ordinary in 1821, and continued to perform them for nearly

forty years. He therefore served under three successive sovereigns,—George IV., William IV., and Victoria,—and although no political or confidential functions are attached to that office, it is one which brings a man into habitual intercourse with the chiefs of all the parties in the state. Well-born, well-bred, handsome, and accomplished, Greville led the easy life of a man of fashion, taking an occasional part in the transactions of his day and much consulted in the affairs of private life. But the celebrity which now attaches to his name is entirely due to the posthumous publication of a portion of a Journal or Diary which it was his practice to keep during the greater part of his life. These papers were given by him to his friend Mr. Reeve a short time before his death (which took place on the 18th January 1865), with an intimation that they should be published, as far as was feasible, at not too remote a period after the writer's death. The journals of the reigns of George IV. and William IV. (extending from 1820 to 1837) were accordingly so published in obedience to his directions about ten years after that event. Few publications have been received with greater interest by the public, five large editions were sold in little more than a year, and the demand in America was as great as in England. These journals were regarded as a faithful record of the impressions made on the mind of a competent observer, at the time by the events he witnessed and the persons with whom he associated. Their characteristic is the love of truth, of justice, and of sincerity. The court was irritated at the scornful disclosure of the vices and follies of former sovereigns, and fashionable society was annoyed at the writer's absolute indifference to its pretensions. But Greville did not stoop to collect or record private scandal. His object appears to have been to leave behind him some of the materials of history, by which the men and actions of his own time would be judged. He records not so much public events as the private causes which led to them, and perhaps no English memoir-writer has left behind him a more valuable contribution to the history of this century. Greville published anonymously, in 1845, a volume on the policy of England to Ireland, in which he advocated the payment of the Roman Catholic clergy, and he was also the author of several pamphlets on the events of his day.

GREW, NATHANIEL (1628-1711), the earliest vegetable anatomist and physiologist of England, was the son of Obadiah Grew, nonconformist divine of St Michael's, Coventry. At the Restoration, his father being ejected from his living, he went to a foreign university, where he took the degree of doctor of physic. Returning to Coventry, his native town, he commenced a series of observations on the physiology of plants, communicating the results to the Royal Society, by which they were so well received that he was induced to remove to London (1672). There he acquired an extensive practice as a physician. He was elected a fellow of the Royal Society on the recommendation of Bishop Wilkins, and in 1677 he succeeded Mr. Oldenburg as secretary, in which capacity he prepared a descriptive catalogue of the rarities preserved at Gresham College (1681). The following year appeared his celebrated work on the *Anatomy of Plants*, in which he displayed great originality as an investigator, especially in pointing out the sex-differences of plants. Linnaeus named a genus of plants *Grewia* (natural family of *Thymaceae*) in his honour. He edited the *Philosophical Transactions*, began in 1665, and wrote treatises on *Sea Water made Fresh*, which passed through several editions, and on the *Natures and Use of the Salt contents in Excess and such other Waters* (1697), a rendering of the *Prædicta de Sali*, &c., &c. (1699). Besides the *Anatomy of Plants*, he wrote a *Comparative Anatomy of Trunks* (1676), and an *Idea of a Physiological History* (1678), as well as *Cosmologia Sacra* (1701). There is also a *Deputatio de Iniquitate* now won by him (1673), and *Deus et deus*. — *sur le combat que se font les éléments du corps* (1670).

GRAY, EARL (1764-1845) Charles, second Earl Grey, was the eldest surviving son of General Sir Charles Grey, afterwards first Earl Grey. He was born at his father's residence, Fallowden, near Altwick, March 13, 1764. General Grey, who was a younger son of the house of Grey of Howick, one of the most considerable territorial families in Northumberland, had already begun a career of active service which, like the political career of his son, covered nearly half a century. Before the latter was born, General Grey had served on the staff of Prince Ferdinand of Brunswick in the Seven Years' War, and had been wounded at Minden. While the son was making verses at Eton, the father was serving against the revolted colonists in Pennsylvania and New Jersey, and while the young member for Northumberland was denouncing Pitt's war against the Convention, the veteran soldier was destroying the remnant of the French colonial empire by the capture of Martinique and Guadeloupe. When Napoleon threatened an invasion, General Grey took the command of the southern district, and at the peace of Amiens he was rewarded with a peerage. His elder brother, Sir Henry Grey of Howick, the head of the family, had supported the Government in parliament. But the political career of young Grey, who was heir presumptive to the family estate, took a different complexion, which needs to be explained by the circumstances in which it began.

Young Grey expected to occupy the seat which had been his uncle's, and his early years were spent in preparation for a parliamentary career. He was sent to Eton, and proceeded thence to Cambridge. William Pitt, a youth five years older, was then in residence as a master of arts, studiously paying court to the Whigs of the university, and at the general election of 1780 he came forward as a candidate for the academical seat. His name stood last on the poll, but he was brought in elsewhere, and his first speech proved him a man of the first rank. The unparalleled successes which followed portended grave changes. Pitt's elevation to the premiership, his brilliant and hard-fought battle in the house, and his complete rout of the Whig party at the general election of 1784, when he came in for Cambridge as the head of the poll, threatened the great territorial interest with nothing less than extinction. It was to this interest that Grey belonged, and hence, when at length returned for Northumberland in 1786, he at once came forward as a vigorous assailant of the Government of Pitt. He was hailed by the opposition, and associated with Fox, Burke, and Sheridan as a manager in the Hastings impeachment. During the nineteen years which remained of the career of Fox, he followed the great Whig statesman with absolute fidelity, and succeeded him as leader of the party. The shortcomings of Fox's statesmanship were inherited by Grey. Both were equally devoid of political originality, shunned the severer labours of the politician, and instinctively feared any deviation from the traditions of their party. Such men cannot save a party in its decadence, and the history of Fox and Grey has been aptly termed the history of the decline and fall of Whiggism.

The stunning blow of 1784 was the first incident in this history. Its full significance was not at once perceived. An opposition, however weak in the beginning, generally has a tendency to revive, and Grey's early successes in the house helped to revive the Foxites. The European situation became favourable to this revival. The struggle in France for popular rights, culminating in the great Revolution, was watched by Fox with interested sympathy. He affected to regard the domination of Pitt as the domination of the crown, and as leading logically to absolutism, and saw in that popular sympathy for the French Revolution which naturally arose in England an instrument which might be employed to overthrow this domination.

But Pitt gathered the fruits of the windfall. The spread of "Jacobinism," or "French principles," became the pretext on which the stronger half of the opposition vented over to the Government. Burke led the movement in the Commons, the duke of Portland and Lord Fitzwilliam in the Lords, and with this second incident in the Whig decline began the difficulties of Grey's career. The domination of the premier had already stirred the keenest resentment in the youngest and more ambitious members of the Whig party. Freed from the restraint of the staid politicians under Burke and Portland, the residium under Fox fell into a series of grave mistakes. Of this residium Grey became the moving spirit, for though Fox did not check their activity, he disclaimed the responsibility of their policy. Fox had refused to condemn "French principles," and denounced the war with France, but he would take no part in exciting agitation in England. It was otherwise with the restless spirits among whom Grey was found. Enraged by the attitude of Pitt, which was grounded on the support of the constituencies as they then stood, the residium plotted an ill-timed agitation for parliamentary reform.

The demand for parliamentary reform was as yet in a rudimentary stage. Fifty years later it had become the demand of an unenfranchised nation, disabused by a sudden spread of political and economical knowledge. It was as yet but the occasional instrument of the scheming politician. Chatham had employed the cry in this sense. The Middlesex agitators had done the same, even the premier of the time, after his accession to power, had sought to strengthen his hands in the same way. But Pitt's hands were now strengthened abundantly, whereas the opposition had nothing to lose and much to gain by such a measure. The cry for reform thus became their natural expedient. Powerless to carry reform in the House, they sought to overawe parliament by external agitation, and formed the Society of the Friends of the People, destined to unite the forces of all the "patriotic" societies which already existed in the country, and to pour their violence uselessly on a terrified parliament. Grey and his friends were enrolled in this potentators' association, and presented in parliament its menacing petitions. Such petitions, which were in fact violent impeachments of parliament itself, proceeding from voluntary associations having no corporate existence, had been hitherto unknown in the English parliament. They had been well known in the French assembly. They had heralded and furthered the victory of the Jacobins, the dissolution of the constitution, the calling of the Convention, and the fall of the monarchy.

The Society of the Friends of the People was originally an after-dinner folly, extemporized at the house of a man who afterwards gained an evil fame by denouncing it as seditious. Fox discountenanced it, though he did not directly condemn it, but Grey was overborne by the fierce Jacobinism of Landale, and avowed himself the parliamentary mouthpiece of this dangerous agitation. But Pitt, strong in his position, cut the ground from under Grey's feet by suppressing the agitation with a strong hand. The suspension of the Habeas Corpus Act, the Gagging Acts, and the state prosecutions form a painful historical episode. But the discredit belongs as much to Grey and Landale as to Pitt. Grey always spoke regretfully of his share in the movement. "One word from Fox," he said, "would have kept me out of all the mess of the Friends of the People." But he never spoke so.

It was Grey who moved the impeachment of Pitt, and he next promoted the equally foolish "Secession." Since the parliament did not properly represent the nation, and refused to reform itself or to impeach the minister, nothing remained but to disown it, and the opposition announced

their intention of "seceding," or systematically absenting themselves from their places in parliament. This futile movement was originated by Grey, Lansdowne, and the duke of Bedford. It obtained a somewhat wider support. It suited the languor of some dispirited politicians, like Fox, and the aversion of some lawyers in large practice, like Eschino, but sensible politicians at once condemned it. It directly ignored parliamentary government, and amounted to nothing but a pettish threat of revolution. "Secession," said Lord Lansdowne, with characteristic shrewdness, "either means rebellion, or it is nonsense." Pitt easily dashed this feeble weapon from the hands of his opponents. He roused jealousy in the absent by passing the bills and the patronage of the rest, and thus gradually brought them back. Grey himself seceded to protest against the union with Ireland.

When Pitt died in 1806, nothing could prevent the united opposition from coming into power, and thus the Broad-bottom ministry was formed under Fox. On his death, Grenville became premier, and Grey, now Lord Howick, Foreign Secretary, and leader of the House of Commons. Disunion, always the bane of English Liberalism, lurked in the coalition, and the Foxites and Grenvillites were only ostensibly at one. Grey opposed the war policy of Grenville, and this policy was not more successful than it had been in the hands of Pitt. And the change from the leadership of Fox to that of Grenville was only too perceptible. Both in court and country Grenville affected the role of Pitt, and assumed a stiff and peremptory attitude which ill became him. An ill-advised dissolution weakened their majority, they lost ground by the "delicate investigation" into the conduct of the Princess of Wales, Lord Henry Petty's budget was too specious to command confidence, and the king, fully aware of their weak situation, resolved to get rid of them. When they proposed to concede a portion of the Catholic claims, George refused, and demanded of them an undertaking never to propose such a measure again. This was refused, and the Grenville Grey cabinet retired in March 1807. In the same year Grey's father died, and Grey went to the Upper House. Opposition united Grey and Grenville for a time, but the parties finally split on the old war question. When Napoleon returned from Elba in 1816, and once more seized the government of France, the same question arose which had arisen in 1792, Was England to go to war for the restoration of the Bourbons? Grenville followed the traditions of Pitt, and supported the ministry in at once renewing hostilities. Grey followed those of Fox, and maintained the right of France to choose her own governors, and the impossibility of checking the reaction in the emperor's favor. The victory of Waterloo put an end to the dispute, but the disruption became permanent. The termination of the war, and the cessation of all action in common, reduced the power of the opposition to nothing. Grenville retired from public life, and his adherents reinforced the ministry. Little remained for the Whigs to do. But the scandalous persecution of the queen afforded an opportunity of showing that the ministry were not omnipotent, and the part taken on that occasion by Grey won him at once the increased respect of the nation and the undying aversion of George IV. It sealed the exclusion of himself and his few friends from office during the king's life, and when in 1827 Grey came forth to denounce the ministry of Canning, he declared that he stood alone in the political world. His words were soon justified, for when Lord Goderich resigned, the remnant which had hitherto supported Grey hastened to support the ministry of the duke of Wellington. Thus was the original Whig party dissolved, after a series of struggles which had begun with the longest reign upon record, and had outlasted it.

We now reach the principal episode in Grey's career. In 1827 he seemed to stand forth, the solitary and powerful relic of an extinct party. In 1832 we find that party restored to its old numbers and activity, supreme in parliament, popular in the nation, and Lord Grey at its head. The duke of Wellington's foolish declaration against parliamentary reform, made in a season of great popular excitement, suddenly deprived him of the confidence of the country, and a coalition of the Whigs and Canningites became inevitable. The Whigs had in 1827 supported the Canningites, the latter now supported the Whigs, of whom Grey remained the traditional head. George IV was dead, and no obstacle existed to Grey's elevation. Grey was sent for by William IV in November 1830, and formed a coalition cabinet, pledged to carry on the work in which the duke of Wellington had faltered. But Grey himself was the mere instrument of the times. An old-fashioned Whig, he had little personal sympathy with the popular cause, though he had sometimes indicated a certain measure of reform as necessary. When he took office, he guessed neither the extent to which the Reform Act would go, nor the means by which it would be carried. That he procured for the country a measure of constitutional reform for which he had agitated in his youth was little more than a coincidence. In his youth he had put himself at the head of a frantic agitation against parliament, because he there found himself powerless. In his old age this case was reversed. Suddenly raised to a position of antithesis in the country, he boldly stood between parliament, as then constituted, and the formidable agitation which now threatened it, and by a forced reform saved it from revolution. In his youth he had assailed Pitt's administration because Pitt's administration threatened with extinction the political monopoly of that landed interest to which he belonged. In his old age, on the contrary, unable to check the progress of the wave, he swam with it, and headed the movement which compelled that landed interest to surrender its monopoly.

The second reading of the first Reform Bill was carried in the Commons by a majority of one. This was equivalent to a defeat, and further failures precipitated a dissolution. The confidence which the bold action of the ministry had won was soon plainly proved, for the second reading was carried in the new parliament by a majority of 136. When the bill had at length passed the Commons after months of debate, it was Grey's task to introduce it to the Lords. It was rejected by a majority of 41. The safety of the country now depended on the prudence and courage of the ministry. The resignation of Grey and his colleagues was dreaded even by the opposition, and they remained in office with the intention of introducing a third Reform Bill in the next session. The last months of 1831 were the beginning of a political crisis such as England had not seen since 1688. The two extreme parties, the Ultra-Radicals and the Ultra-Tories, were ready for civil war. Between them stood the ministry and the majority of intelligent peace-loving Englishmen, and their course of action was soon decided. The bill must be passed, and there were but two ways of passing it. One was to decline the consent of the House of Lords unnecessary to the measure, the other to create, if necessary, new peers in sufficient number to outvote the opposition. These two expedients did not in reality differ. To swamp the house in the way proposed would have been to destroy it. The question whether the ministry should demand the king's consent to such a creation, if necessary, was debated in the cabinet in September. Brougham proposed it, and gradually a majority of the cabinet were won over. Grey had at first refused to employ even the threat of so unconstitutional a device as a means to the proposed end. But his continued refusal would have broken up the ministry, and the breaking

up of the ministry must now have been the signal for revolution. The second reading in the Commons was passed in December by a majority of 162, and on New-Year's Day 1832 the majority of the cabinet resolved on demanding power to carry it in the Lords by a creation of peers. Grey carried the resolution to the king. Some time still remained before the bill could be committed and read a third time. It was not until the 9th of April that Grey moved the second reading in the Lords. A sufficient number of the opposition temporized, and the second reading was allowed to pass by a majority of nine. Then the intention was to mutilate the bill in committee. The Ultra-Tories, headed by the Duke of Wellington, had entered a protest against the second reading, but they were now politically powerless. The struggle had become a struggle on the one hand for the whole bill, to be earned by a creation of peers, and on the other for some mutilated measure. Grey's instinct divined that the crisis was approaching. Either the king must consent to swamp the House, or the ministry must cease to stand in the breach between the peers and the country. The king, a weak and inexperienced politician, had in the meantime been wrought upon by the temporizing leaders in the Lords. He was induced to believe that if the Commons should reject the mutilated bill when it was returned, to amend, and the ministry should consequently refuse, to amend, the bill might be reintroduced and passed by a Tory ministry. He was deaf to all representations of the state of public opinion, and to the surprise of the ministry, and the terror and indignation of every man of sense in the country, he rejected their proposal, and accepted their resignation, May 9, 1832. The Duke of Wellington undertook the hopeless task of constituting a ministry which should pass a restricted or sham Reform Bill. The only man who could have made the success of such a ministry even probable was Peel, and Peel's conscience and good sense forbade the attempt. He refused, and after a week of the profoundest agitation throughout the country, the king, beaten and mortified, was forced to send for Grey and Brougham. On being told that his consent to the creation of peers was the only condition on which they could undertake the Government, he angrily and reluctantly yielded. The chancellor, with cool forethought, demanded this consent in writing. Grey thought such a demand harsh and unnecessary. "I wonder," he said to Brougham, when the interview was over, "you could have had the heart to press it." But Brougham was inexorable, and the king signed the following paper:—"The king grants permission to Earl Grey, and to his Chancellor, Lord Brougham, to create such a number of peers as will be sufficient to ensure the passing of the Reform Bill, that calling up peers' eldest sons—WILLIAM R. WINDSOR, May 17, 1832." This brief paper may be called the Magna Charta of responsible government. It established the right of a ministry to break down, by some convenient means, a factious opposition in the Lords, and this right has never since been practically disputed.

Grey had now won the game. There was no danger that he would have to resort to the expedient which he was authorized to employ. The introduction of sixty new peers would have destroyed the opposition, but it would have been equivalent to the abolition of the House. The king's consent made known, a sufficient number of peers were sure to withdraw to enable the bill to pass, and thus the dignity of both king and peerage would be saved. The Duke of Wellington headed this movement on the part of the opposition, and the third reading of the bill was carried in the Lords by a majority of 84.

It is well known that in after years both Grey and Brougham disclaimed any intention of executing their

threat. If this were so, they must have merely pretended to brave a danger which they secretly feared to face, and intended to avoid, and the credit of securing the country would belong to the duke of Wellington and the peers who sided with him. To argue such cowardice in them from statements made when the crisis was long past, and when they were naturally willing to palliate the rough policy which they were forced to adopt, would be to set up a need less and unjustifiable pseudo-historicism. Nothing else in the career of either Grey or Brougham leads us to suppose men capable of the moral baseness of yielding up the helm of state, in an hour of darkness and peril, to reckless and unskilled hands. Such would have been the result if they had lacked the determination to carry out their programme to the end. The influence of every statesman in the country would then have been extinguished, and the United Kingdom would have been absolutely in the hands of O'Connell and Orator Hunt.

Grey took but little part in directing the legislation of the reformed parliament. Never anxious for power, he had executed the arduous task of 1831-2 rather as a matter of duty than of inclination, and wished for an opportunity of retiring. Such an opportunity very shortly presented itself. The Irish policy of the ministry had not conciliated the Irish people, and O'Connell denounced them with the greatest bitterness. On the renewal of the customary Coercion Bill, the ministry was divided on the question whether to continue to the lord lieutenant the power of suppressing public meetings. Mr. Littleton, the Irish secretary, was for abolishing it, and with the view of conciliating O'Connell, he informed him that the ministry intended to abandon it. But the result proved him to have been mistaken, and O'Connell, with some reason supposing himself to have been duped, called on Mr. Littleton to resign his secretaryship. It had also transpired in the discussion that Lord Althorp, the leader of the House of Commons, was privately opposed to retaining those clauses which it was his duty to push through the house. Lord Althorp therefore resigned, and Grey, who had lately passed his seventieth year, took the opportunity of resigning also. It was his opinion, it appeared, which had overborne the cabinet in favour of the public meeting clauses, and his voluntary withdrawal enabled Lord Althorp to retain to his post, and to proceed with the bill in its milder form. Grey was succeeded by Lord Melbourne, but no other change was made in the cabinet. Grey took no further part in politics. During most of his remaining years he continued to live in retirement at Howick, where he died on the 17th of July 1845, in his eighty-second year. By his wife Mary Elizabeth, only daughter of the first Lord Ponsonby, whom he married November 15, 1794, he became the father of ten sons and five daughters, of whom eight sons and four daughters survived him.

In public life, Grey could always be upon occasion bold, strenuous, and self-sacrificing, but he was little disposed for the active work of the politician. He was not one of those who took the statesman's duty "as a pleasure he was to enjoy." A certain stiffness and reserve ever seemed in the popular eye to hedge him in, nor was his oratory of the kind which stirs enthusiasm and delight. A tall, stately figure, fine voice, and calm aristocratic bearing reminded the listener of Pitt rather than of Fox, and his speeches were constructed on the Attic rather than the Asiatic model. Though simple and straightforward, they never lack either point or dignity, and they were admirably adapted to the audience to which they were addressed. The scrupulous uprightness of Grey's political and private character completed the ascendancy which he gained, and no politician could be named who, without being a statesman of the highest class, has left a name more envially placed in English history. (A. J. P.)

GREY, LADY JANE (1537-1554), a person remarkable no less for her accomplishments than for her misfortunes, was the great-granddaughter of Henry VII of England. Her descent from that king was traced through a line of females. His second daughter Mary, after being left a widow by Louis XII of France, married Charles Brandon, duke of Suffolk, who was a favourite with her brother King Henry VIII. Of this marriage came two daughters, the elder of whom, Lady Frances Brandon, was married to Henry Grey, marquis of Dorset, and their issue, again, consisted of daughters only. Lady Jane, the subject of this article, was the eldest of these whom the marquis had by Lady Frances. Thus it will appear that even if the crown of England had ever fallen into the female line of descent from Henry VII, she could not have put in a rightful claim unless the issue of his elder daughter, Margaret, had become extinct. But Margaret had married James IV of Scotland, and, though her descendant, James VI, was ultimately called to the English throne, Henry VIII had placed her family after that of his second sister in the succession, so that, failing the lawful issue of Henry himself, Lady Jane would, according to this arrangement, have succeeded. It was to these circumstances that she owed her exceptional position in history, and became the victim of an ambition which was not her own.

She was born at her father's seat named Broadgate in Leicestershire, about the year 1537. Her parents, though severe disciplinarians, bestowed more than ordinary care upon her education, and she herself was so teachable, and delighted so much in study, that she became the marvel of the age for her acquirements. She not only excelled in needlework and in music, both vocal and instrumental, but whilst still very young she had, thoroughly mastered Latin, Greek, French, and Italian. She was able to speak and write both Greek and Latin with an accuracy that satisfied even such critics as Ascham and her tutor Dr. Aymer, afterwards bishop of London. She had also acquired some knowledge of at least three Oriental tongues, Hebrew, Chaldean, and Arabic. In Ascham's *Schoolmaster* is given a touching account of the devotion with which she pursued her studies and the happiness she experienced from her parents. The love of learning was her solace, in reading Demosthenes and Plato she found a refuge from domestic unhappiness. After the fashion of those days she was, when about ten years old, placed for a time in the household of Thomas, Lord Seymour, who induced her parents to let her stay with him by promising to marry her to his nephew King Edward VI. Lord Seymour, however, was attainted of high treason and beheaded in 1549, and his brother, the duke of Somerset, made some overtures to the marquis of Dorset to marry her to his son the earl of Hertford. These projects, however, came to nothing. The duke of Somerset in his turn fell a victim to the ambition of Dudley duke of Northumberland, and was beheaded three years after his brother. Meanwhile, the dukedom of Suffolk having become extinct by the deaths of Charles Brandon and his two sons, the title was conferred upon the marquis of Dorset, Lady Jane's father. Northumberland, who was now all-powerful, fearing a great reverse of fortune in case of the king's death, whose health soon began visibly to decline, endeavoured to strengthen himself by marriages between his family and those of other powerful noblemen, especially of the new-made duke of Suffolk. His three eldest sons being already married, the fourth, who was named Lord Guildford Dudley, was accordingly wedded to Lady Jane Grey about the end of May 1553. The match received the full approval of the king, who furnished the wedding apparel of the parties by royal warrant. But Edward's state of health warned Northumberland that he must lose no time in putting the rest of his project into

execution. He persuaded the king that if the crown should descend to his sister Mary, the work of the Reformation would be undone and the liberties of the kingdom would be in danger. Besides, both Mary and her sister Elizabeth had been declared illegitimate by separate Acts of Parliament, and the objections to Mary Queen of Scots did not require to be pointed out. Edward was easily persuaded to break through his father's will and make a new settlement of the crown by deed. The document was witnessed by the signatures of all the council and of all but one of the judges, but those of the latter body were not obtained without difficulty by threats and intimidation.

Edward VI. died on the 6th July 1553, and it was announced to Lady Jane that she was queen. She was then but sixteen years of age. The news came upon her as a most unwelcome surprise, and for some time she resisted all persuasions to accept the fatal dignity, but at length she yielded to the entreaties of her father, her father-in-law, and her husband. The better to mature their plans the cabal had kept the king's death secret for some days, but they proclaimed Queen Jane in the city on the 10th. The people received the announcement with manifest coldness, and a stranger's boy was even so bold as to tease a way for Queen Mary, for which he next day had his ears nailed to the pillory and afterwards out of Mary, however, had received early intimation of her brother's death, and, retiring from Hunsdon into Norfolk, gathered round her the nobility and commons of those parts. Northumberland was despatched thither with an army to oppose her, but after reaching Newmarket he complained that the council had not sent him forces in sufficient numbers, and his followers began to desert. News also came that the earl of Oxford had declared for Queen Mary, and as most of the council themselves were only seeking an opportunity to wash their hands of rebellion, they granted a meeting at Baynard's Castle, revoked their former acts as done under coercion, and caused the lord mayor to proclaim Queen Mary, which he did amid the shouts of the citizens. The duke of Suffolk was obliged to tell his daughter that she must lay aside her royal dignity and become a private person once more. She replied that she relinquished most willingly a crown that she had only accepted out of obedience to him and her mother, and her ten days' reign was over.

The leading actors in the conspiracy were now called to answer for their deeds. Northumberland was taken up to London a prisoner, tied and sent to the block, along with some of his partisans. The duke of Suffolk and Lady Jane were also committed to the Tower, but the former, by the influence of his duchess, procured a pardon. Lady Jane and her husband Lord Guildford Dudley were also tried, and received sentence of death for treason. Thus, however, was not immediately carried out, on the contrary the queen seems to have wished to spare their lives, and mitigated the rigour of their confinement. Unfortunately, owing to the general dislike of the queen's marriage with Philip of Spain, Sir Thomas Wyatt soon after raised a rebellion in which the duke of Suffolk and his brothers took part, and on its suppression the queen was persuaded that it was unsafe to spare the lives of Lady Jane and her husband any longer. On hearing that they were to die, Lady Jane declined a parting interview with her husband lest it should increase their pain, and prepared to meet her fate with Christian fortitude. She and her husband were executed on the same day, February 12, 1554, her husband on Tower Hill, and herself within the Tower an hour afterwards, amidst universal sympathy and compassion.

GREYHOUND See Dog, vol vii p 327, and Cousins.

GREYTOWN, or more correctly San Juan del Norte, a small town of Nicaragua, worthy of note as the only port of the republic on the coast of the Atlantic and as the eastern terminus proposed for the Nicaraguan inter-oceanic canal. According to the survey of Commanders Hatfield and Lull, U.S.N., in 1872-3, the church is situated in 10° 55' 14" N lat and 83° 42' 18" W long. The town lies along the seaward side of a narrow peninsula formed by the windings of the San Juan river, and most of its buildings are insignificant erections raised 2 or 3 feet on piles. Though it is still a port of call for mail steamers, and monopolizes the export and import trade of Nicaragua, Greytown is in a deplorable condition. Its fine harbour has become almost useless. Between 1832 and 1848 the Arenas Point, which formed one of its boundaries, advanced westward nearly a nautical mile, and now the whole seaward frontage of the bay is a moving sand-bank. In 1853 the channel of entrance was still about one third of a mile in width and had 23 to 25 feet of water in the bar, so that even vessels of war were able to take shelter within the harbour, but by 1861 the channel was only 100 yards wide and 12 feet deep, and in 1875 the passage was sometimes practically closed, with at the most only 3 feet of water. The inhabitants of the town, however, have increased from 985 in 1863 to about 1900 in 1875. As the vicinity of their town is unfitted for agriculture, they are almost entirely dependent for provisions on supplies from the interior or abroad, and sometimes the commonest articles of consumption are exceedingly scarce. In terms of the treaty of 1860 trial by jury is maintained in all civil and criminal cases, and there is perfect freedom of religious worship, both private and public. The seventh article, however, by which Greytown was to remain a free port has become a dead letter. A duty of 5 per cent was allowed by the merchants on all imports consumed in the place in order to provide means for constructing a lighthouse, and in 1863 the central Government of the republic imposed another 5 per cent, so that all goods really pay 10 per cent *ad valorem*. The imports in 1875 and 1878 respectively were £25,350 and £105,000, and the exports £60,500 and £145,000.

The harbour of San Juan, first discovered by Columbus, was brought into further notice by Captain Diego Michena, who in 1629 sailed down the river from the Lake of Nicaragua. The site of the first Spanish settlement on the spot is not known, but in the 17th century there were fortifications at the mouth of the river. In 1796 San Juan was made a port of entry by royal charter, and new defences were erected in 1821. The town was seized by the place at the revolution, but they were expelled in January 1848 by the British, who, claiming the district in name of the "King of the Mosquito Indians," continued in possession till the treaty of 1860. In 1861 the town was bombarded by the United States forces for an alleged insult.

GRIBOYEDOFF, ALEXANDER SERGUEVICH (1796-1829), was born in 1796 at Moscow, where he studied at the university from 1810 to 1812. He then obtained a commission in a Russian regiment, but resigned it in 1816. Next year he entered the civil service, and in 1818 was appointed secretary of the Russian legation in Persia, whence he was transferred to Georgia. There he began the drama which has made him famous. He had commenced writing early, and had produced on the stage at St Petersburg in 1816 a comedy in verse, translated from the French, called *The Young Spouse*, which was followed by some other pieces of the same kind. But neither these, nor the essays and verses which he wrote for periodicals, would have been long remembered, but for the immense success gained by his comedy in verse, *Goré et vna*, or "Misfortune from Intelligence." A satire upon Russian society, or, as a high official styled it, "A pasquade on Moscow," its

plot is slight, its merits consisting in its accurate representation of certain social and official types,—such as Faucoussé, the lover of old abuses, the hater of reforms, his secretary, Molchann, seville fawner upon all in office, the autocratic young liberal and Anglomane, Repetshoff, contrasted with whom is the hero of the piece, Tolstaksky, the nominal artist, just returned from the west of Europe, who exposes and ridicules the weaknesses of the rest, his words echoing that outcry of the young generation of 1820 which reached its climax in the military insurrection of 1826, and was then sternly silenced by Nicholas. Griboyedoff spent the summer of 1823 in Russia, completed his play, and took it to St Petersburg. There it was rejected by the censorship. Many copies were made and privately circulated, but Griboyedoff never saw it published. The first edition was printed in 1833, four years after his death. Only once did he see it on the stage, when it was acted by the officers of the garrison at Erivan. Soured by disappointment he returned to Georgia, made himself useful by his linguistic knowledge to his relative Count Paskievitch-Erivanisky during a campaign against Persia, and was sent to St Petersburg with the treaty of 1828. Brilliantly received there, he thought of devoting himself to literature, and commenced a romantic drama, *A Georgian Night*. He was suddenly sent to Persia as Russian plenipotentiary. Soon after his arrival at Tcheban a tumult arose, caused by the anger of the populace against some Georgian and Armenian captives,—Russian subjects,—who had taken refuge in the Russian embassy. It was stormed, Griboyedoff was killed (February 11, 1829), and his body was for three days so ill-treated by the mob that it was at last recognized only by an old seal on the hand, due to a wound received in a duel. It was taken to Tiflis, and buried in the monastery of St David. There a monument was erected to his memory by his widow, to whom he had been but a few months married. But his memory is best preserved by his play *Goré et vna*, which has since his death been repeatedly published and performed, and will always be quoted as one of the masterpieces of Russian literature. An English translation by N Benadsky appeared in London in 1857.

GRIEBACH, JOHANN JAKOB (1745-1812), one of the most distinguished of the band of scholars to whom the modern science of New Testament textual criticism owes its origin, was born at Butzbach, a small town of Hesse-Darmstadt, where his father was pastor, on the 4th of January 1745. He received his school education at Frankfurt-on-the-Main, and carried on his university studies at Tübingen and Leipzig, but especially at Halle, where he became one of Semler's most ardent disciples. At the close of his undergraduate career, he undertook a literary tour, which, apart from the advantages of stimulative contact with many of the most distinguished scholars of England, France, and Holland, as well as of his own country, was of great utility to him in providing him with materials for the great work of his subsequent life. On his return to Halle, he acted for some time as "privat-docent," but in 1773 was appointed to a professorial chair, in 1775 he was translated to Jena, where the remainder of his life was spent in ever-increasing usefulness and honour, and where he died 24th March 1812.

Griebach's critical edition of the New Testament first appeared at Halle, in three volumes, in 1774-76. The first volume contained the first three gospels, synoptically arranged, the second, the fourth gospel and the Acts of the Apostles. All the historical books were reprinted in one volume in 1777, the synoptical arrangement of the gospels having been abandoned as inconvenient. Of the second edition, very considerably enlarged and improved, the first volume appeared in 1796 and the second in 1808 (Halle and London). Of a third edition, edited by Schulz, only the first volume, containing the four gospels, has appeared (1827).

For the construction of his critical text Griebach took as his

tales under the title of *Holland Tale* was so successful that he at once set about the preparation of a similar series, which appeared the same year in two volumes under the title of *Tales of the Alsatian Festivals*, and were still more popular. In 1838 appeared the *Collegian*, afterwards so successfully adapted for the stage under the title of the *Colleen Bawn*. It is said to have been the favourite novel of O'Connell, and, besides exhibiting that masterly delineation of both the pathetic and the humorous features of Irish character already shown in his other works, it was written with a veve and a dramatic intensity and realism far surpassing all his previous or subsequent efforts. His principal other works are *The Invision*, *The Rivals*, *Tracey's Ambition*, and *The Tales of Two Senses*. He is also the author of a number of lyrics which are generally pervaded by a tender and sad sentiment. When Griffin appeared to have achieved the literary success for which he had had such a hard struggle, he began to feel a growing distaste for his profession. He became doubtful as to the moral influence of his writings, and as to whether on that account he had not been "mispending his time," and ultimately he came to the conclusion that his true sphere of duty was to be found within the walls of a monastery,—a resolve doubtless partly attributable to the state of his health. He was admitted into a Dublin monastery in September 1838 under the name of Brother Joseph, and in the following summer he removed to Cork, where he died of typhus fever 12th June 1840. Previous to adopting the monastic habit he burned all his manuscripts, but *Quixote*, a tragedy which he had composed in his twenty fifth year, accidentally escaped destruction, and in 1842 was put on the Drury Lane stage by Mr Macready, and acted with great success. The collected works of Gerald Griffin were published in 1848 in eight volumes, with a memoir by his brother. See also *Dublin University Magazine* for February 1844.

GRILLPARZER, FRANZ (1791–1873), a distinguished German dramatist, was born in Vienna on the 15th January 1791. His father, a respectable advocate, destined him for his own profession, but on the conclusion of his legal studies, in 1811, Grillparzer became a tutor in a noble family, and two years afterwards accepted a subordinate post in the civil service. He rose slowly in his profession, but in 1833 was made director of the archives in the court chamber (Hofkammer). He retired in 1856, receiving the title of Hofrath, a title which was replaced in 1861 by the higher one of Reichsrath. In 1847 he was made a member of the Academy of Sciences. From early youth he displayed a strong literary impulse. He devoted especial attention to the Spanish drama, and nearly all his writings bear marks of the influence of Calderon. When he began to write, the German stage was dominated by the wild plays of Weisse, Mullner, and other authors of the so-called "fate-tragedies." His first play, *Die Ahnfrau* (The Ancestress), published in 1816, was penetrated by their spirit. A lady, who has been slain by her husband for infidelity, is doomed to visit "the glimpses of the moon" till her house is extinguished, and this end is reached in the tragedy amid scenes of violence and horror. Some of Grillparzer's admirers draw a sharp distinction between this play and the works with which it is usually classed, and in doing so they follow his own example. But its general character is exactly similar to that of Werner's dramas; it only differs from them in containing individual passages of much force and beauty. It at once became extremely popular, and Grillparzer was encouraged to write a second, *Sappho* (1819) the most artistically finished of his productions. An Italian rendering of this play fell into the hands of Lord Byron, who, although the translation was very bad, expressed his conviction that the author's name would be held in reverence by posterity. It is full of the

aspiration of the Romantic school, but its form is classic, and its chastened style presents a striking contrast to the noise and fury of the *Ahnfrau*. The problem of the play has some resemblance to that of Goethe's *Torquato Tasso*, for in both we find the struggles of a poetic nature which is unable to reconcile itself to the conditions of the actual world. Grillparzer's conceptions are not so clearly defined as Goethe's, nor is his diction so varied and humorous, but the play has the stamp of genius, and ranks as one of the best of those works in which an attempt has been made to combine the passion and sentiment of modern life with the simplicity and grace of ancient masterpieces. Another and more ambitious work in the classic style was *Das goldene Vlies* (The Golden Fleece), a trilogy published in 1823. Of its three parts the greatest is *Medea*, which some critics consider his highest achievement. There is delicate art in the delineation of the mingled fascination and repulsion which Medea and Jason feel for each other, and when at last repulsion becomes the dominant force, the dramatist gives splendid utterance to the rage of the disappointed wife and mother. In *Des Meeres und der Liebe Wellen* (Waves of the Sea and of Love), which appeared in 1840, Grillparzer again formed his work on classic models, but in this instance his feeling is so distinctly modern that it does not find adequate expression in his carefully measured verse. The subject is the story of Hero and Leander, and it has never been more happily treated than in some passages, which, however, are marked rather by lyrical than dramatic qualities.

In 1825 Grillparzer published *König Ottokar's Glück und Ende* (King Ottokar's Fortune and End). It appealed strongly to the patriotic sympathies of Vienna, dealing as it does with one of the proudest periods of Austrian history,—the time of Rudolf I., the founder of the house of Hapsburg. In a harsh criticism of Grillparzer, which appeared in the *Foreign Review* in 1829, and is now included in his *Miscellaneous*, Mr Carlyle said that Schiller's *Piccolomini* differed from *Ottokar* as "a living rose [differs] from a mass of dead rose leaves, or even of broken Italian gladioli." This judgment has not been confirmed by later criticism. It cannot, indeed, be said that the materials of the play are welded into a compact whole, but the characters are vigorously conceived, and there is a fine dramatic contrast between the brilliant, restless, and unscrupulous Ottokar and the calm, upright, and ultimately triumphant Rudolf. Another historical play, *Ein treuer Diener seines Herrn* (A faithful Servant of his Lord), appeared in 1830, and brought down upon the author a storm of abuse from the liberals, who accused him of servility. On the other hand, the play displeased the court, and its representation was stopped. It hardly deserved to be made the subject of so much contention, for it is one of the least powerful of Grillparzer's later dramas. A more pleasing work was the dramatic study *Des Trauens, ein Leben* (The Dream, a Life), which is to some extent a direct imitation of Calderon, and has something of his brilliance and charm. In the same year in which this was issued (1840) Grillparzer published *Wohle dem der lügt* (Woe to him who Lies), a comedy. It was so badly received that he wrote no more for the stage. Several dramatic fragments, however, composed at a later time, appeared among his posthumous writings.

Grillparzer was a lyrical as well as a dramatic poet. He used to say that all his lyrics were written for the purpose of obtaining relief from feelings by which he happened to be oppressed. The same thing was said of himself by Goethe, but Goethe's emotion in passing into verse was purified and generalized, Grillparzer's remained for the most part strictly personal, and rarely touches the deepest sympathies. He is more successful in epigram, in which

he often gives sharp expression to a keen, biting humor. He wrote also several prose tales, one of which, *Der Spedmann* (The Murrman), is marked by delicate and graceful fancy. His autobiography, which was written in 1853 and brings down the narrative of his life to 1836, is a model of clear, simple, and elegant prose, and it throws much interesting light both on his personal character and on the tendencies of his time. Among his posthumous writings are many fragments of literary, philosophic, and political criticism, all of them indicating a strong and independent spirit, not invariably just, but distinct, penetrating, and suggestive. It is characteristic of him that he expresses extreme dislike of Hegel's philosophy on the ground that its terms are unintelligible. On the other hand, he gives evidence of careful and sympathetic study of Kant. Of modern literary critics Gervinus was most repugnant to him, mainly because of the tendency of this writer to attribute moral aims to authors who created solely for art's sake. He rather maliciously says that Gervinus had one advantage and one disadvantage in writing his history of German Literature,—the advantage of common sense, the disadvantage of knowing nothing of his subject.

Of a quiet contemplative nature, Gulliparzi shunned general society. He never married. To a stranger he seemed cold and distant, but in conversation with any one he liked his real disposition revealed itself, his manner became animated, his eyes brightened, and his sarcastic but not ill-natured smile would play upon his lips. It was one of his sayings that the art of writing poetry can neither be taught nor learned, but he also held that inspiration will not visit a poet who neglects to make himself master of his subject. Hence before writing a play he worked hard, striving to comprehend the spirit of the age he wished to represent. He was exceedingly fond of travel, and at different times visited all the leading European countries. After 1840, when his solitary comedy was rejected by the public, he almost passed from the memory of his contemporaries. Fortunately for him, Heinrich Laube, an admirer of his genius, settled in Vienna in 1849 as artistic director of the court theatre. By and by Laube introduced on the stage some of the forgotten works, and their success was immediate and profound. To his own surprise, Gulliparzi became the most popular author of the day, he was ranked with Goethe and Schiller, and lauded as the national poet of Austria. On the eightieth anniversary of his birthday all classes from the court downwards united to do him honour, never, probably, did Vienna exact herself so much to prove her respect for a private citizen. He died on the 21st January 1872, and was buried with an amount of ceremony that surpassed even the pomp displayed at Klopstock's funeral. A monument of him has recently been erected at Baden, near Vienna.

After his death an admirable edition of his works, in ten volumes, was issued by Heinrich Laube and J. Widen. There are several English renderings of *Sappho*, and *Medea* has also been translated. For biographical and critical notices see Kuhn, *Zwei Dichter Oesterreichs* (Leith, 1872), Böttger-Poll, *Gulliparzi und seine Werke* (Stuttgart, 1875), and Goldschmidt, "Franz Gulliparzi," and "Franz Gulliparzi Nachlass," in *Unsere Zeit* for 1872 and 1878. (J. ST.)

GRIMALDI, GIOVANNI FRANCESCO (1606-1680), an architect and painter, named Il Bolognese from the place of his birth, was a relative of the Caracci family, under whom it is presumed he studied first, and afterwards under Albano. He went to Rome, and was appointed architect to Pope Paul V., and patronized by succeeding popes also. Towards 1648 he was invited to France by Cardinal Mazarin, and for about two years was employed in buildings for that minister and for Louis XIV., and in fresco-painting in the Louvre. His colour was strong, somewhat excessive in the use of green, his touch light. He painted at once

history, portraits, and landscape,—the last with predilection, especially in his advanced years,—and executed engravings and etchings from his own landscapes, and from those of Titian and the Caracci. Returning to Rome, he was made president of the Academy of St Luke, and in that city he died on 28th November 1680, in high repute not only for his artistic skill but for his upright and chasteable deeds as well. His son Alessandro assisted him both in painting and in engraving. Paintings by Grimaldi are preserved in the Quirinal and Vatican palaces, and in the church of S Martino a' Monti, there is also a series of his landscapes in the Colonna Gallery.

GRIMM, FRIEDRICH MELCHIOR, BARON VON (1723-1807), the author of the celebrated *Correspondance litteraire*, was, though a naturalized Frenchman, both of German descent and a native of Germany, having been born of poor parents at Ratzbach, 36th December 1723. He studied at the university of Leipzig, where he had as professor the celebrated Ernesti, to whom he was doubtless in no small degree indebted for his critical appreciation of classical literature. On completing his studies he made his literary debut by a tragedy which was received with ridicule by the audience and by the critics, including Lessing, and which is now forgotten even in Germany. In all probability it was this disappointment which led him to think of seeking his fortune in Paris, whither he accompanied the count of Schöberg as tutor to his sons, and where afterwards, at a small salary, he was for some time reader to the young hereditary prince of Saxe-Cotha. In 1749 he made the acquaintance of J. J. Rousseau, which, through a mutual sympathy in regard to musical matters, soon ripened into intimate friendship. Through Rousseau he was introduced to the Encyclopedists, and about the same time he became secretary to Count Friesen, nephew of Marshal Saxe, which gained him admission to the most brilliant society of Paris. Endowed with more than average intellectual abilities, thoroughly versed in all current topics of interest in literature, science, and art, gifted with remarkable insight into character, possessing engaging manners and great social tact, and actuated in all his conduct by a keen regard to his own interest, he won almost immediately general appreciation and respect. He rapidly obtained a thorough knowledge of the French language, and acquired so perfectly the tone and sentiments of the society in which he moved that all marks of his foreign origin and training seemed completely effaced. A witty pamphlet entitled *Le petit Propriete de Boecksmuscheloda*, written by him on the respective merits of the Italian and French operas, a subject which at that time greatly exercised the society of Paris and on which he sided with the Italian section, at once firmly established his literary reputation. It is possible that the origin of the pamphlet is partly to be accounted for by his admiration of Mlle Fel, the *prima donna* of the Italian company. This admiration quickly developed into a passion so vehement that he was seized with a kind of cataplexy which continued for several days, but from which he suddenly awoke completely recovered both in body and mind. In 1753 Grimm was engaged by the Abbé Raynal to aid him in conducting his literary correspondence with German sovereigns, and this opened up to him that sphere for his ambition which perhaps was most in accordance with his peculiar tastes, and in which his abilities best fitted him to excel. Although from the beginning he had the principal share in the work, it was probably conducted until 1759 in the name of the Abbé Raynal. With the aid of friends during his temporary absences from France he carried it on until 1790, and it latterly extended to six sovereigns, including the empress of Russia, the king of Sweden, and the king of Poland. It was probably in 1754 that Grimm was introduced by Rousseau to Madame

d'Épinay, his relations with whom led to an irreconcilable rupture between him and Rousseau. The exact amount of Grimm's blameworthiness it is impossible to determine, and the whole matter would be of little consequence but for the fact that Rousseau allowed his resentment to gain such a complete possession of his mind as to induce him to give in his *Confessions* a wholly mendacious portrait of Grimm's character, by which his reputation was for a considerable time injuriously affected. After the death of Count Friesen-Grimm obtained the patronage of the duke of Orleans, through whom he was appointed secretary to Marshal d'Estades during the campaign of Westphalia in 1756-57. Subsequently he became minister of Saxo-Gotha at the court of France, but he was deprived of that office on account of having criticized rather caustically certain French ministers in a pamphlet that was intercepted by Louis XV. His introduction to Catherine II of Russia took place in 1773, when he accompanied the suite of the landgrave of Hesse-Darmstadt to St. Petersburg on occasion of the marriage of a daughter of that prince to the only son of Catherine. After the Revolution Grimm retired to Gotha, and in 1792 he emigrated to Russia, where he enjoyed high favour at the court of Catherine, and had assigned him the nominal and agreeable duty of entertaining her for so many hours a day by his conversation. His state of things came, however, to an end in 1795, when, notwithstanding his supplications to be retained at court if only as one of her majesty's dogs, he was appointed minister of Russia at Hamburg. He died at Gotha, 19th December 1807.

The correspondence of Grimm forms perhaps the most valuable of existing records of any important literary period. It embraces nearly the whole period from 1750 to 1790, and although parts of it during his absence from France were written by Diderot, Madame d'Épinay, and others, the work as a whole may be regarded as substantially his. At first he contented himself with enumerating in the simplest manner the chief current views in literature and art, and indicating only very slightly the contents of the principal new books, but gradually his criticisms became more extended and trenchant, and he touched on nearly every subject—political, literary, artistic, social, and religious—which interested the Parisian society of the time—his narrative, which moves lightly and easily from one theme to another, being frequently seasoned by piquant anecdotes or witty reflections. Not only, however, did he aim to give a faithful and just account of the subjects on which he wrote, his purpose extended considerably beyond that of affording a few hours' amusement to his royal patrons, and his descriptions and criticisms were fitted to satisfy more than a superficial curiosity. His notices of contemporaries are somewhat severe, and he exhibits in all the nakedness of truth the follies and selfishness of the society in which he moved, but he appears to have been unbiassed in his literary judgments, and such is their justness and penetration that time has only served to confirm them. In style and manner of expression he is thoroughly French. He is generally somewhat cold in his appreciation, but his literary taste is delicate and subtle, and it is the opinion of Sainte-Beuve that the quality of his thought in his best moments will compare not unfavourably even with that of Voltaire. His religious and philosophical opinions were entirely negative, and his references to Christianity generally assume the form of either a sneer or a whim.

Grimm's *Correspondance littéraire, critique, par le 1753 à 1770*, was published at Paris in 1813 in 5 vols. 8vo., *deuxième partie* du 1771 à 1782, in 1812 in 5 vols. 8vo., and *troisième partie*, pendant une partie des années 1775 à 1778, et pendant les années 1782 à 1790 inclusivement, in 1813 in 8 vols. 8vo. A supplementary volume appeared in 1814, the whole correspondence was collected and published by M. Jules Tschischau in a

Nouvelle édition, revue et mise dans un meilleur ordre, avec des notes et des éclaircissements, et où se trouvent établis pour la première fois les phrases supprimées par la censure impériale, Paris, 1829-1831, 15 vols. 8vo., and the *Correspondance littéraire, pendant la durée de la révolution française, et jusqu'à la chute de la censure impériale* in 1812 et 1813 was published in 1829. Grimm's *Almanach historique sur l'époque et les suites de mon ottomanement par l'empereur et par Catherine II. jusqu'à ce jour de ce moment jusqu'à ce jour*, and Catherine's correspondence with Grimm to September 1774, have been published in the *Collection of the Russian Imperial Historical Society*. She tells him very familiarly, and calls him Tschichte, George Dandin, &c. He signs himself 'Plémeur'. See also *Almanach d'Épinay*, *Almanach*, Rousseau's *Confessions*, the notice by Giguère in the introduction to the second part of the *Correspondance*, and that by Tschischau in the introduction to the new edition, Sainte-Beuve, *Critique des Laites*, vol. vii.

GRIMM, JACOB LUDWIG CARL (1785-1863), was born on the 4th of January 1785 at Hanau, in Hesse-Cassel. His father, who was a lawyer, died while he was still a child, and the mother was left with very small means, but her sister, who was lady of the chamber to the landgrave of Hesse, helped to support and educate her numerous family. Jacob with his younger brother Wilhelm (born on the 24th of February 1788) was sent in 1798 to the public school at Cassel. In 1802 he proceeded to the university of Marburg, where he applied himself to the study of law, a profession for which he had always been inclined by his father, and which seemed to offer the best prospect of speedy independence. His brother joined him at Marburg a year later, having just recovered from a long and severe illness, and likewise begun the study of law. Up to this time Grimm had been actuated only by a general thirst for knowledge and the instinct of intellectual activity, and his energies had not found any aim beyond the practical one of making himself a position in life. The first definite impulse came from the lectures of Savigny, the celebrated investigator of Roman law, who, as Grimm himself says (in the preface to the *Deutsche Grammatik*), first taught him to realize what it meant to study any science, whether that of law or any other. Savigny's lectures at the same time awakened in him that love for historical and antiquarian investigation which forms the basis of all his work. Then followed personal acquaintance, and it was in Savigny's well provided library that Grimm first turned over the leaves of Bodmer's edition of the Old German manuscripts, and other early texts, and felt an eager desire to penetrate further into the obscurities and half-revealed mysteries of that language. In the beginning of 1805 he received an invitation from Savigny, who had removed to Paris to continue his researches among the libraries there, to join him and help him in his literary work. This offer was joyfully accepted by young Grimm, who passed a very happy time in Paris, enjoying the society of Savigny, and strengthening his taste for the literature of the Middle Ages by his studies in the Paris libraries. Towards the close of the year he returned to Cassel, where his mother and Wilhelm had settled, the latter having finished his studies. The next year he obtained a situation in the war office with the very small salary of 100 thalers. One of his grievances was, as he himself tells us in his autobiography, that he had to exchange his stylish Paris suit for a stiff uniform and gaiter. But he had full leisure for the prosecution of his studies. In 1808, soon after the death of his mother, he was appointed superintendent of the private library of Jerome Buonaparte, king of Westphalia, into which Hesse-Cassel had been incorporated by Napoleon. He was treated with marked favour by the king, who appointed him an auditor to the state council, while he still retained his other post. His salary was increased in a short interval from 2000 to 4000 francs, which removed all anxiety as to the means of subsistence, and his official duties were hardly more than nominal. After the expulsion of Jerome and the reinstatement of an elector, Grimm was appointed in 1813 secretary of legation,

to accompany the Hessian minister to the headquarters of the allied army. In 1811 he was sent to Paris to demand restitution of the books carried off by the French, and in 1814-15 he attended the congress of Vienna as secretary of legation. On his return he was again sent to Paris on the same errand as before. Meanwhile Wilhelm had received an appointment in the Cassel library, and in 1816 Jacob was made second librarian under Volkel. On the death of Volkel in 1828 the brothers expected to be advanced to the first and second librarianships respectively, and were much dissatisfied when the first place was given to Rommel, keeper of the archives. So they removed next year to Göttingen, where Jacob received the appointment of professor and librarian, Wilhelm that of under-librarian. Jacob Grimm lectured on legal antiquities, historical grammar, literary history, and diplomatics, explained Old German poems, and commented on the *Germania* of Tacitus. At this period he is described as small and lively in figure, with a harsh voice, speaking a broad Hessian dialect. His powerful memory enabled him to dispense with the "heft" which most German professors rely on, and he spoke extempore, referring only occasionally to a few names and dates written on a slip of paper. He himself regretted that he had begun the work of teaching so late in life, and as a lecturer he was not successful; he had no idea of digesting his facts and suiting them to the comprehension of his hearers, and even the brilliant, terse, and eloquent passages which abound in his writings lost much of their effect when jotted out in the midst of a long array of dry facts. In 1837, being one of the seven professors who signed a protest against the king of Hanover's abrogation of the constitution which had been established some years before, he was dismissed from his professorship and banished from the kingdom of Hanover. He returned to his native Cassel together with his brother, who had also signed the protest, and remained there till, in 1840, they accepted an invitation from the king of Prussia to remove to Berlin, where they both received professorships, and were elected members of the Academy of Sciences. Not being under any obligation to lecture, Jacob very seldom did so, but together with his brother worked at the great dictionary, the plan of which had already been fully developed. During their stay at Cassel Jacob regularly attended the meetings of the academy, where he read papers on the most varied subjects. The best known of these are those on Lachmann, Schiller, and his brother Wilhelm (who died in 1859), on old age, and on the origin of language. He also described his impressions of Italian and Scandinavian travel, interspersing his more general observations with linguistic details, as in the case in all his works. He died in 1863, working up to the last.

Grimm's physical constitution was an excellent one. He possessed in the highest degree that Teutonic energy and endurance which are as essential to the sedentary student as to the pioneer in other regions of human activity. He was never ill, and worked on all day, without haste and without pause. He himself (in his biography) speaks of his "non industry." He was not at all impatient of interruption, but seemed rather to be refreshed by it, returning to his work without effort. He wrote for press with great rapidity, and hardly ever made corrections. He never revised what he had written, remarking with a certain wonder of his brother, "Wilhelm reads his manuscripts over again before sending them to press." He often started on a journey which he had determined upon only the day before. His temperament was uniformly cheerful, and he was easily amused. He took a keen interest in politics, and when the newspapers arrived, he would often read them through at once, breaking off his work for the purpose. Outside his own special work he had a marked taste for botany, and always liked

to have flowers about him while working, a taste which was shared by his brother. The spirit which animated his work is best described by himself at the end of his autobiography: "Nearly all my labours have been devoted, either directly or indirectly, to the investigation of our earlier language, poetry, and laws. These studies may have appealed to many, and may still appeal, useless, to me they have always seemed a noble and earnest task, definitely and inseparably connected with our common fatherland, and calculated to foster the love of it. My principle has always been in these investigations to under-value nothing, but to utilize the small for the illustration of the great, the popular tradition for the elucidation of the written monuments." We may, in fact, sum up Grimm's tendencies by saying that he was inspired by an intense enthusiasm for research, guided into definite channels by a not less enthusiastic love and veneration for everything German,—this word including, in its widest sense, all the great brotherhood of the Teutonic nations,—and limited by his decided predilection for history and antiquities. It will be observed that, whenever he refers to living dialects or traditions, it is in order to throw light on the past, not the reverse. Even in his great German dictionary the historical tendency strongly predominates.

The purely scientific side of Grimm's character developed itself but slowly, and it was long before he applied to the study of etymology and induction the system and method Savigny had taught him to develop in legal history. He seems to have felt the want of definite principles of etymology without being able to discover them, and indeed even in the first edition of his grammar (1819) he seems to be often groping in the dark, and to have but a vague idea of the necessity of rigorous principles of letter-comparison. As early as 1815 we find A. W. Schlegel reviewing the *Alteutsche Wälder* (a periodical published by the two brothers) very severely, condemning the lawless etymological combinations it contained, and insisting on the necessity of strict philological method and a fundamental investigation of the laws of language, especially in the correspondence of sounds. This criticism is said to have had a considerable influence on the direction of Grimm's studies.

The first work he published, *Ueber den altheidischen Mysteriensang* (1811), was of a purely literary character. But even here we see the difference between the more passive contemplation of the æsthetic literary critic and the activity of the investigator who is always seeking definite results and definite laws. In this essay Grimm showed that *Minnensang* and *Mysteriensang* were really one form of poetry, of which they merely represented different stages of development, and also announced his important discovery of the unvariable division of the *Lied* into three strophic parts.

His text editions were mostly prepared in common with his brother. In 1812 they published the two ancient fragments of the *Ulied* and the *Wessensbrunnener Gêd*, Jacob having discovered what till then had never been suspected—the alteration in these poems. However, Jacob had but little taste for text-editing, and, as he himself confessed, the evolving of a critical text gave him little pleasure. He therefore left this department to others, especially Lachmann, who soon turned his brilliant critical genius, trained in the severe school of classical philology, to Old and Middle High German poetry and metre. Both brothers were attracted from the beginning by all national poetry, whether in the form of epics, ballads, or popular tales. They published in 1816-18 an analysis and critical sifting of the oldest epic traditions of the Germanic races under the title of *Deutsche Sagen*. At the same time they collected all the popular tales they could find, partly from

the mouths of the people, partly from manuscripts and books, and published in 1812-15 the first edition of these *Kinder und Haus-Märchen* which have caused the name of the brothers Grimm into every household of the civilized world, and founded the science of what is now called folk lore. The closely allied subject of the satirical beast epic of the Middle Ages also had a great charm for Jacob Grimm, and he published an edition of the *Reinhart Fuchs* in 1834. His first contribution to mythology was the first volume of an edition of the Eddic songs, undertaken conjointly with his brother, published in 1815, which, however, was not followed by any more. The first edition of his *Deutsche Mythologie* appeared in 1835. This great work covers the whole range of the subject, tracing the mythology and superstitions of the old Teutons back to the very dawn of direct evidence, and following their decay and loss down to the popular traditions, tales, and expressions in which they still linger.

Although by the introduction of the Code Napoléon into Westphalia Grimm's legal studies were made practically barren, he never lost his interest in the scientific study of law and national institutions, as the truest exponents of the life and character of a people. By the publication (in 1828) of his *Rechtsalterthümer* he laid the foundations of that historical study of the old Teutonic laws and constitutions which has been continued with brilliant success by Maurer and others. In this work Grimm showed the importance of a linguistic study of the old laws, and the light that can be thrown on many a dark passage in them by a comparison of the corresponding words and expressions in the other old cognate dialects. He also knew how—and this is perhaps the most original and valuable part of his work—to trace the spirit of the laws in countless allusions and sayings which occur in the old poems and sagas, or even survive in modern colloquialisms.

Of all his more general works the boldest and most far-reaching is unquestionably his *Geschichte der deutschen Sprache*, where at the same time the linguistic element is most distinctly brought forward. The subject of the work is, indeed, nothing less than the history which lies hidden in the words of the German language—the oldest national history of the Teutonic tribes determined by means of language. For this purpose he laboriously collects the scattered words and allusions to be found in classical writers, and endeavors to determine the relations in which the German language stood to those of the Celts, Thracians, Scythians, and many other nations whose languages are known to us only by doubtfully identified, often extremely corrupted remains preserved by Greek and Latin authors. It need hardly be said that Grimm's results have been greatly modified by the wider range of comparison and improved methods of investigation which now characterize linguistic science, while, on the other hand, many of the questions raised by him will probably for ever remain obscure, but his book will always be one of the most fruitful and suggestive that have been ever written.

We now come to his purely philological work, of which his famous *Deutsche Grammatik* was the outcome. We have already seen how slowly and with what difficulty he attained a sound method of etymological and grammatical investigation. Nevertheless the time was a favourable one for his work. The persevering labours of past generations—from the humanists onwards—had collected an enormous mass of materials in the shape of text editions, dictionaries, and grammars, although most of it was uncritical and often untrustworthy. Something had even been done in the way of comparison and the determination of general laws, and the conception of a comparative Teutonic grammar had been clearly grasped by the illustrious Englishman Hooke, at the beginning of the last century, and partly carried out by

him in his *Thesaurus*. Ten Kate in Holland had afterwards made valuable contributions to the history and comparison of the Teutonic languages. Even Grimm himself did not at first intend to include all the languages in his grammar, but he soon found that Old High German postulated Gothic, that the later stages of German could not be understood without the help of the Low German dialects, including English, and that the rich literature of Scandinavia could as little be ignored. The first edition of the first part of the *Grammatica*, which appeared in 1819, and is now extremely rare, treated of the inflexions of all these languages, together with a general introduction, in which he vindicated the importance of a historical study of the German language against the *a priori*, quasi philosophical methods then in vogue.

In 1832 this volume appeared in a second edition—really a totally new work, for, as Grimm himself says in the preface, it cost him little reflexion to mow down the first crop to the ground. The wide distances between the two stages of Grimm's development in those two editions is significantly shown by the fact that while the first edition gives only the inflexions, in the second volume phonology takes up no less than 600 pages, more than half of the whole volume. Grimm had, at last, awakened to the full conviction that all sound philology must be based on rigorous adhesion to the laws of sound-change, and he never afterwards swayed from this principle, which gave to all his investigations, even in their boldest flights, that iron-bound consistency, and that force of conviction which distinguishes science from dilettantism, up to Grimm's time philology was—as it still is in England—nothing but a more or less laborious and conscientious dilettantism, with occasional flashes of scientific inspiration, he made it into a science. His advance must be attributed mainly to the influence of his contemporary Rask. Rask was born two years later than Grimm, but his remarkable precocity gave him somewhat the status of an elder brother. Even in his first edition Grimm's Icelandic paradigms are based entirely on Rask's grammar, and in his second edition he has relied almost entirely on Rask for Old English. His debt to Rask can only be estimated at its true value by comparing his treatment of Old English in the two editions, the difference is very great. Thus in the first edition he declines *dear*, *degas*, plural *degaras*, not having observed the law of vowel-change pointed out by Rask. There can be little doubt that the appearance of Rask's Old English grammar was a main inducement for him to recast his work from the beginning. To Rask also belongs the merit of having first distinctly formulated the laws of sound correspondence in the different languages, especially in the vowels, those more fleeting elements of speech which had hitherto been ignored by etymologists.

This leads us to a question which has been the subject of much controversy,—What discovered Grimm's law? The law of the correspondence of consonants in the older Indo-Germanic, Low, and High German languages respectively was first fully stated by Grimm in the second edition of the first part of his grammar. The correspondence of single consonants had been more or less clearly recognised by several of his predecessors, but the one who came nearest to the discovery of the complete law was the Swede Ihre, who established a considerable number of "literary permutations," such as *b* for *f*, with the examples *bawu = fawu*, *beftu = fetu*. Rask, in his essay on the origin of the Icelandic language, gives the same comparisons, with a few additions and corrections, and even the very same examples in most cases. As Grimm in the preface to his first edition expressly mentions this essay of Rask, there is every probability that it gave the first impulse to his own investigations. But there is a wide difference between the isolated

permutations of his predecessors and the comprehensive generalizations under which he himself ranged them. The extension of the law to High German is also entirely his own. The only fact that can be adduced in support of this assertion that Gumm was to deprive Rask of his claims, to priority is that he does not expressly mention Rask's results in his second edition. But this is partly of the plumb of Rask, made up entirely by his enormous talent, to sweep asunder from all controversy the defense of the works of others, leaving his readers to assign to each investigator his due. In his first edition he expressly calls attention to Rask's essay, and praises it most ungrudgingly. Rask himself refers as little to Thre, merely alluding in a general way to Thre's permutations, although his own debt to Thre is infinitely greater than that of Gumm to Rask or anyone else. It is true that a certain bitterness of feeling afterwards sprang up between Gumm and Rask, but this was due to a misunderstanding, which was entirely avoidable and unstable in controversy, refused to acknowledge the value of Gumm's views, when they involved modification of his own. The importance of Gumm's generalization in the history of philology cannot be overestimated, and even the mystic completeness and asymmetry of its formulation, although it has proved a luminance to the correct explanation of the causes of the changes, was well calculated to strike the popular mind, and give it a vivid idea of the paramount importance of law, and the necessity of discussing the changes in terms of law. The English and French English etymologist bows down to the authority of Gumm's law, though it must be confessed he honors it almost as much in the breach as in the observance.

The grammar was continued in three volumes, treating principally of derivation, composition, and syntax, which last was left unfinished. Grimm then began a third edition, of which only one part, comprising the vowels, appeared in 1840, his time being afterwards taken up mainly by the dictionary. Of the grammar as a whole we can only say that it is a masterpiece of exhaustive treatment, of comprehensive, method, and fullness of detail. Every law, every letter, every syllable of inflexion in the different languages, is illustrated by an almost exhaustive mass of material, drawn from every period and every dialect. It has served as a model for all succeeding investigators. Diez's grammar of the Romance languages is founded on it, and the Germanic languages which it treated, have found influence on the wider study of the Indo-Germanic languages in general.

To the great German dictionary Gimm undertook a task for which he was hardly suited. His exclusively historical tendencies made it impossible for him to do justice to the individuality of a living language, and the disconnected statement of the facts of language in an ordinary alphabetical dictionary fatally mars its scientific character. It was also undertaken on so large a scale as to make it impossible for him and his brother to complete it themselves. We may describe the dictionary, as far as it was worked out by Gimm himself, as a collection of disconnected antiquarian essays of, it need hardly be remarked, high value.

In summing up Gurnam's scientific character we are struck by his combination of breadth and unity. He was as far removed from the narrowness of the specialist who has no ideas, no sympathies beyond some one author, period, or narrow corner of science, as from the shallow dabbler who feverishly attempts to master the details of half a dozen discordant pursuits, which have no central point of interest around which to rally. Even within his own special studies there is the same wide concentration, no *Mexzofanti-like* parrot display of useless polyglotism. The very foundations of his nature were harmonious, his patriotism and

love of historical investigation received then full satisfaction in the study of the language, traditions, mythology, laws, and literature of his own countrymen and their nearest kindred. But from this centre his investigations were pursued in every direction as far as his unquiet instinct of healthy limitation would allow. He was equally fond of the study of the history of the laws, the literature, the social and moral nature. He made cheerfully the heavy sacrifices that science demands from its disciples, without feeling any of that envy and bitterness which often torment weak natures, and although he lived apart from his fellow men, he was full of human sympathies, and no man has ever exercised a profounder influence on the destinies of mankind than he—an influence which is still only in its infancy. He was the very ideal of the noblest type of German character.

The following is a complete list of his separately published works, those which he published in common with his brother being marked with a star. For a list of his essays in periodicals, &c., see vol. v of his *Kleinere Schriften*, from which the present list is taken. His life is best studied in his own "Selbstbiographie," in vol. i of the *Kleineren Schriften*. There is also a brief memoir by Dr Godeke in *Göttinger Professoren*, Götta (Pöthkes), 1872.

[illegible]

GRIMM, WILHELM CARL (1786-1866). The chief events in the life of Wilhelm Grimm have been narrated in last article. The two brothers were indeed so intimately associated both in their lives and in their works that a separate biography of the younger is almost superfluous. As Jacob himself said in his celebrated address to the Berlin Academy on the death of his brother, the whole of their lives were passed together. In their school-days they had one bed and one table in common, as students they had two beds and two tables in the same room, and they always lived under one roof, and in the same books, and their lives were so intermingled that Wilhelm's biography in general was and disturbs their harmony. As Cleasby said ("Life of Cleasby," prefixed to his *Kelends Dictionary*, p. lxx), "that they both live in the same house, and in such harmony and community that one might almost imagine the children were common property." Wilhelm's character was a complete contrast to that of his brother. As a boy he was strong and healthy, but as he grew up he was attacked by a long and severe illness, which left him weak all his life. His was a less comprehensive and energetic mind than that of his brother, and he had less of the spirit of investigation in him, preferring to confine himself to some limited and definitely bounded field of work, he utilised everything that bore directly on his own theme, and ignored the rest. These studies were always literary, and literary men and the study of his works, including those which carried on in common with his brother, are concerned either with literary problems, or popular traditions, or else are text-editions. It is characteristic of his more æsthetic nature that he took great delight in music, for which his brother had but a moderate liking, and had a remarkable gift of story-telling. Cleasby, in the account of his visit to the brothers, quoted above, tells that

"Wilhelm read a sort of farce written in the Frankfort dialect, depicting the 'malheurs' of a rich Frankfort tradesman on a holiday jaunt on Sunday. It was very dull, and he read it adriftably." Cleverly describes him as "an uncommonly amiable, jovial fellow." He was, accord- ingly, much sought in society, which he frequented much more than his brother.

His first work was a spirited translation of the Danish *Kæmpevisen* (the mischievous Heldenliedchen), published in 1811-18, which attracted great attention, and made his name as a writer widely known throughout his land. The most important of his text editions, viz.—*Richtschied-Jede*, Göttingen, 1838; *Kommt aus Harburg's Golden Schwanke*, Berlin, 1840; *Olaf Rudolfs*, Göttingen, 1844 (2d ed.), *Atlas und Fingerring*, Berlin, 1846; *Altdeutsche Geographie*, Berlin, 1851; *Frühling*, Göttingen, 1860 (2d ed.) Of his other works the most important is *Deutsche Heldenage*, Berlin, 1868 (2d ed.) His *Deutsche Riesen* (Göttingen, 1821) has now only an historical interest.

GRAMMA, a town in the circle of Leipzig, Saxony, is situated on the left bank of the Mulde, 19 miles S E of Leipzig. In the Middle Ages it was an important commercial town, but agriculture is now its principal industry, although its manufactures have for some time been increasing. Besides huge flour-mills there are yarn-bleaching and dyeing works, and outside the town are the Gölz-mühle, which include an iron foundry and manufactures of paper and machinery. The principal buildings are the old castle, founded in the 12th century, in which the margraves of Meissen and the electors of Saxony often held court, the town house, dating from 1442, the two normal semi- naries, the real school of the second order, and the famous *Pfisterkirche* (*Heilige Moldenau*) seated by the elector Maurice on the site of the former Augustine monastery and consecrated in 1850, having provision for 104 free scholars and 22 boarders, and a library now numbering 10,000 volumes. In the immediate neighbourhood are the Cistercian monastery in which Catherine von Bora lived, and the village of Döben, with an old castle in which Albert the Proud kept his father Otto the Rich prisoner. Gramma is of Sorbian origin, and came into the possession of Germany through the emperor Henry I. The population in 1875 was 7273.

GRIMSBY, GRANT, a municipal and parliamentary borough and seaport town of England, county of Lincoln, is situated on the south side of the estuary of the Humber nearly opposite Spurn Head, and 17 miles E S E of Hull. Since the opening in 1855, under the auspices of the Manchester, Sheffield, and Lincolnshire Railway Company, of extensive docks occupying a space of 140 acres reclaimed from the sea, the shipping trade of Grimsby has largely increased. A new dock connecting the royal dock with the old dock was opened by the Prince of Wales July 22, 1870. A dock of 26 acres in extent for the accommodation of the coal and timber trade is in course of construction, and it is proposed still to supply additional dock accommodation by reclaiming 200 more acres from the Humber. In 1877 the number of British vessels that entered the port was 2837, with a tonnage of 855,218, of foreign vessels 847, with a tonnage of 258,243, the number of British vessels that cleared 2642, with a tonnage of 342,727, of foreign vessels 743, with a tonnage of 235,486. Steamers ply regularly between Grimsby and the most important Baltic ports. Until 1868 no fishing trawlers had their headquarters at Grimsby, but since that period they have so increased that in 1877 the fishing craft numbered 506, with a tonnage of 29,924, and Grimsby has now become one of the largest fishing ports in the kingdom. For the use of the fishing vessels a special dock of 13 acres in extent was constructed, and another of 11 acres has lately been finished, as well as a graving dock capable of holding ten smacks at a time. Ice companies have also been established, with steamers of their own for

conveying ice from Norway for the use of the fisheries. Further particulars regarding the fishing trade of Grimsby will be found under the article *FISHERIES*, vol. ix. pp. 248, 250. The principal other industries are shipbuilding, iron and brass founding, brewing, and tanning. The chief buildings, besides the large warehouses extending along the docks, are the fine old parish church (restored in 1859), the free grammar school, the custom house, the mechanics' institute, the hospital, the coin exchange, and the town-hall. A statue of the Prince Consort was unveiled 23d July 1879. The population of the municipal borough in 1861 was 11,007, and of the parliamentary borough 15,060, in 1871 the numbers were 20,244 and 26,982. The area of the former is 1737, and of the latter 16,830 acres.

Grimsby is supposed to have been the spot where the Danes landed on their first invasion of Britain. It is so strongly by the sea, and one of the most ancient in the kingdom. In the reign of Edward III. it was a considerable seaport, and in 1346 it furnished that monarch with 11 ships and 170 men-of-war for the siege of Calais. After that period its trade fell into decay through the gradual blocking up of the harbour by the accumulation of mud and sand, until the erection of new docks about the beginning of the present century. By the Act of 23d Edward I. the town obtained the privilege of returning two members to parliament, but since the Reform Act of 1832 it has returned only one.

GRINDAL, EDWARD (c. 1510-1563), archbishop of Canterbury, was born at Hoxingham in the parish of St. Peter, Cambridgeshire, about 1519. He was educated at Cambridge, where he became fellow of Pembroke Hall in 1538, and president in 1549. In the following year he was appointed chaplain to Bishop Ridley, in August 1551 precentor of St. Paul's, in November chaplain to Edward VI., and in July 1552 prebendary of Westminster. On the accession of Mary in 1553 he took refuge on the Continent, staying chiefly at Strasburg, where he acquired a competent knowledge of German, and occupied himself also in collecting the "writings and stories of the learned and pious sufferers in England,"—the result of his inquiries being afterwards communicated to John Foxe, and incorporated by him in his *Book of Martyrs*. Returning to England under the new regime in 1568, he assisted in the preparation of the new liturgy, and was also one of the eight Protestant divines chosen to hold public disputes with the papal prelates. In 1569 he was appointed to the mastership of Pembroke Hall, and in the same year he succeeded Bonner as bishop of London, in which capacity he, along with Archbishop Parker, shared in 1569 in the responsibility of suspending those of the London clergy who refused to submit to the Act of Uniformity, on which account an indignant mob of clergymen's wives appeared before his house at St. Paul's, and were with difficulty persuaded by one of the suspended clergymen to go away quietly. In 1570 Grindal was appointed to the see of York, from which he was translated to Canterbury in February 1576. Having in the same year incurred the royal displeasure by refusing to suppress the meetings held among the clergy for "the exercise of prophesying," he was ultimately, in June 1577, by order of the Star Chamber confined to his house and sequestered for six months. As in November he refused to make a formal submission to the queen, his suspension was continued for several years. But though a petition for his restoration, which was drawn up by convocation in 1580, was not immediately granted, it would appear that in 1582 he had resumed, at least partially, the exercise of his ecclesiastical functions. About the end of this year the queen, on account of his blindness, requested him to resign a pension, but the negotiations connected with his resignation were not completed till April 1583, and it was only after his death at Croydon, July 6th of the same year, that Whitgift, who had been nominated his successor, entered upon the see. Though

Grindal yielded to the pemptory orders of Elizabeth in regard to the clergy who refused to sign the Act of Uniformity, he seems on all other occasions, while conducting himself with great moderation and manifesting unvarying courtesy and an earnest desire to avoid every cause of offence, to have strenuously upheld the spiritual independence of his office. His aims were on the whole noble and unselfish, and he was zealous in his endeavours to reform the abuses of his predecessors, to improve the moral and intellectual status of the clergy, and as far as possible to conciliate and reclaim the Puritans. He was sincerely attached to Protestantism, and laid much stress on the function of preaching, a "gift" in which he himself is said to have excelled. Grindal is alluded to (as *Almund*) in the seventh "eclogue" of Spenser's *Shepherd's Calendar*.

His literary remains, which are unimportant, have been published by the Parker Society, with a biographical notice by the Rev Wm Nicholson, 1853. See also *Styke's Life of Grindal*, London, 1710, Oxford, 1821. *A Brief and True Account of Edmund Grindal*, 1710. *Memoirs respecting his Suspension, &c*, supposed by some to have been written by Stucheville, 1710, a *Life of Watling*, and Hook's *Lives of the Archbishops of Canterbury*, vol. viii.

GRINDSTONE Sandstones which possess the property of abrad- ing steel and other hard substances are extensively used in arts and manufactures under the name of grindstones. In its simplest form a grindstone consists of a stone disc, more or less circular, mounted on a horizontal spindle carried on the tops of two wooden posts fixed in the ground. A wrench handle, or occasionally a rude crank with treads, provides the means of giving a slow rotation to the stone, against the cylindrical face of which the steel or other substance which is to be ground is held. Such grindstones—possessing neither truth of figure nor the means of obtaining it—are unsuitable for any but the roughest purposes, and although by mounting them in a frame to which a rest can be attached it is possible to keep them true and tolerably efficient, they are always slow in their action.

Cutlers employ grindstones which are roughly mounted but which are well being driven at a much higher speed by a strap from a large wheel or pulley, and they carefully preserve the truth of the cylindrical face. And in many manufacturing processes the surface speed of the face is still further increased by employing very large stones, and giving them the greatest number of revolutions per minute that is compatible with safety,—this limit even being sometimes exceeded, when the centrifugal force overcomes the rather slight cohesive strength of the stones, and breaks them up into fragments which fly to great distances with disastrous results. Sandstone suitable for grindstones of various degrees of hardness and fineness is found in the coal districts of the north of England, and also in those of the midland counties. A favourite stone for tool grinding at a low speed is quarried at Bilston in Staffordshire. The neighbourhood of Sheffield also affords some useful qualities of grindstones.

Artificial grindstones closely resembling the natural stones, but of perfectly uniform texture, which the natural ones frequently are not, were made a few years ago by Mr Ransome's ingenious process. Their manufacture has been discontinued, but artificial grindstones of another kind, made with emery instead of sand, are now effecting a complete revolution in the art of the machinist. By means of these emery grinders, to which great variety of size and form can be given so as to suit the particular purposes for which they are intended, the operation of turning up metal surfaces by hand, whether they are large or small, curved or flat, can in very many kinds of work be entirely dispensed with,—the results being superior in truth of figure, uniform in all cases, and obtained in a mere fraction of the time which the most skilful workman would require. The

extensive use of these grinders in America (where the importance of labour saving machines is properly appreciated) renders it certain that the system will gradually make its way also in England, and that hand filing will thus to a large extent be superseded,—files being costly instruments in themselves, and many times more costly in their use, owing to the skill which they demand on the part of the workman who handles them.

Artificial wheels made with emery are by no means a new invention. In India and China they have been used for centuries, but being made with lac and similar fusible materials, such wheels are not capable of being run at the high rate of speed which is a first essential to their efficiency. Others, however, which were not liable to these objections were made and patented in England more than thirty years ago, and it is surprising that these have not been more generally used. The chief advantage of those now made,—some of which are manufactured in the United States, some on the continent of Europe, and some in England,—is that they can be obtained of large size—up to about 3 feet in diameter—and that they are strong enough to be driven at a very high speed without breaking. At a surface speed of 5000 or 6000 feet per minute these wheels cut tempered steel readily, when used either wet or dry, and by their means it can be shaped, if necessary, in its hardest condition, with a facility previously unobtainable. And in the case of common grindstones, truth of form is most important to their efficient working, and it is therefore desirable that the work under treatment should be held perfectly rigid, by means of some form of sliding rest, or otherwise. When so used the wear of the emery wheel, which is exceedingly slow, keeps it constantly true without attention. If from any cause this truth of figure be lost, or if it be desired to alter the form of the face, recourse must be had to turning it up with a diamond, nothing else in nature being sufficiently hard for the purpose.

GRINGOIRE, or **GRINGON**, **PRINCE** (c. 1480–1544), was the last of the mediæval poets. He lived to see the old methods which he was taught to believe unchangeable entirely superseded. He was born about the time when King René, the last of the princely *trouvères*, died, he finished his career when Marot had already introduced a new and natural *genre* which he could not understand, and when Ronsard and Baif were beginning those studies which would interpose a barrier between the old language and the new. It was not to be expected that he should ever fall in with the new movements, or that he should understand the enormous value of the changes which were destined to consign his own works to oblivion.

The place of his birth is uncertain. Perhaps it was Lorraine, perhaps Normandy. His real name was Gringon, which he changed to Gringoire, for the poetical reason that it sounded better. His early history is almost entirely unknown, at the age of nineteen or twenty he produced his first poem, *Le Chateau de Labou*, in which he is supposed to have narrated his own experiences. Most probably he did René, Charles of Orleans, François, Dauphins, all the poets whose works he would study, began with a poetical exposition of their own experiences. There are, in Gringoire's poem, the personages common to all mediæval allegories, *Raison*, *Bonne Volonté*, *Talent de beau faire*, *Les amis*, *Le Souverain*, *Le Prince*, and the rest, for enemies. Finding that the trade in allegorical poems was runned for want of demand, and discovering an opening in the direction of mysticism, Gringoire began to produce those dramas, and joined the "Enfants de Sans Souci." The fraternity advanced him to the dignity of "Mère Sotte," and afterwards to the highest honour of the guild, that of "Prince des Sots." For twenty years Gringoire seems to have been

at the head of this illustrious *conférence*, writing for them farces, *actes*, and satires. In this capacity of dramatist he exercised an extraordinary influence. At no time was the stage, rude and coarse as it was, more popular as a true exponent of the popular mind. Gringore's success lay in the fact that he followed, but did not attempt to lead, on his stage the people saw exhibited their passions, their judgments of the moment, their jealousies, their hatreds, and their ambitions. Brotherhoods of the kind existed all over France. In Paris there were the "Enfants Sans Souci," the "Daseocheins," the "Confiance de la Passion," and the "Souverain Empereur de Gahlé," at Dijon there were the "Mise Folle" and her family, in Flanders the "Société des Auteurs" played comedies, at Rouen the "Comédiens" or "Comands" yielded to none in vigor, and fearlessness of satire. There is every reason, therefore, to believe that Gringore enjoyed considerable distinction as the leading spirit among the satirists of the capital. He adopted for his device, *Tout par Raison, Raison par Tout, Pas tout Raison*. He has been called the "Aristophanes des Halles." In one respect at least he resembled Aristophanes. He is serious in his merriment, there is purpose behind his extravagances. Among his principal works are *Les Folles Entreprises* and *Les Abus du Monde*,—poems in which everything under the sun is criticized,—certain political pieces, such as *La Chasse du Cœur des Cœurs* (*Seuf des Seufs, &c.*, *seus seus wuh*), under which title he has literally oglepunged. During the last twenty years of a long life he became orthodox, and contributed the *Blasons des Hérétiques* to orthodox literature. It was during this period also that he wrote the work by which he is best known, the *Mystère de la Vie de Saint Louis*, of which an analysis may be found in M. Leroy's *Études sur les Mystères*. After more than 300 years of oblivion this poem has been republished, not so much on account of his own merits as because of the position which he occupies in the history of dramatic literature.

GRUQUAND WEST, a province in South Africa, comprising the territory formerly belonging to the western division of the Griqua people, which was annexed to the British empire October 27, 1871. The extent of the province is 17,800 square miles. It is bounded on the S by the Orange River (which separates it from the Cape Colony), on the N and NE by territory occupied by the Bechuana tribes and the Transvaal settlement, and on the E by the Orange Free State. The general elevation of the country is about 3000 feet above sea-level, its characteristic features are undulating grassy plains, alternating with low ranges of rocky hills and sandy downs. The Vaal river flows through the principal districts, receiving in its course the Hart River and Modder River, with its affluent the Rust River, before its junction with the Orange River. A portion of the territory is adapted for sheep-farming, and the river basins contain fertile lands suitable for agricultural purposes. But the great wealth of the country is in its diamond mines. Since the first discovery of diamonds, in 1867, the total value of the gems exported from the province up to the close of the year 1878 is estimated at £20,000,000. Digging operations were at first confined to the alluvial deposits on the banks of the Vaal River, but in 1871 mines were opened in the locality known as the "dry diggings," which have since received the names of Kimberley, De Beers, Du Toit's Pan, and Bultfontein, all situated within a radius of a few miles. The mode of the diamond-producing process at all of these places is distinctly defined. At Kimberley the mine covers only 9 acres, at De Beers 1½ acres, at Du Toit's Pan 41 acres, and at Bultfontein 22 acres. These circular areas appear to be "throats" or "pups" through which the volcanic and

serpentine matter containing the sparkling gems have been erupted, the surrounding rock consists of sandstones and shales entirely barren of diamonds. Kimberley, the chief centre of the mining industry, is the capital of the province and the seat of government. There is a resident lieutenant governor or administrator, who is assisted by an executive council, and a legislative council composed of members partly elective and partly nominated by the crown. There is also a high court of justice presided over by a resident recorder. The other towns are Du Toit's Pan (including Bultfontein), Barkly, and Griqua Town. The villages and native locations are Helyon, Likaalong, Botsap, Campbell, and Douglas. Among the river diggings or encampments are Pniel, Waldeck's Plant, Sifonell, and Setacone's. A census taken in 1877 showed the total population of Griqualand West at that time to be 45,277, of whom 12,347 were Europeans.

GRISONS (German, *Graubünden*) is the largest and easternmost of the Swiss cantons. It is 80 miles in length from ENE to WSW, and 45 in breadth, and has an area of 2963 square miles. On the NE and E it abuts against the little principality of Liechtenstein, and the Austrian provinces of Tyrol and Vorarlberg, on the S on the Italian provinces of Val Tellina and Como, and on the W and N on the Swiss cantons of Ticino, Uri, Glarus, and St. Gall.

The whole canton is mountainous, and, with the exception of the Rhine valley below Reichenau and the Italian valleys, which still form part of it, has a severe alpine climate and vegetation. One tenth of the surface is covered by glaciers. The five principal glacier groups are those of the Toled, N, the Medelser Gebüge and the Rhenwald or Adula Gebüge, containing the chief source of the Rhine, SW, the Bernina group, the largest and loftiest, SE, and the Silvretta Gebüge, E. The principal valleys are the Vorder and Hinter Rhenndale, with their side-ways the Valserthal, Averserthal, Oberhalbstein, and Piatsgan, forming together the upper basin of the Rhine. Besides these, the canton includes the long narrow trough of the upper Inn, and the Italian valleys of Nisacco, Bregaglia, and Poschiavo, whose streams join the Ticino or the Adde. The high average elevation of the country, with the absence of any large lake, renders the scenery more severe than that of central Switzerland, and the mountain summits less imposing. The most fertile valleys are the Piatsgan and Rhenndale below Ilanz. The lower chains are rent by many great gorges. The Via Mala, the Rofa, and the Schyn are the best known, but those of the Zuga, the Averserthal, Medelserthal, and Valserthal are almost equal to them in grandeur. In the Rhenndale below Chur the vine flourishes best, the usual products of the southern slope of the Alps, maize and chestnuts. At Poschiavo tobacco is cultivated to some extent. The inner valleys are the highest of Central Europe, containing several villages at an elevation of about 6000 feet (St. Moritz, Engadine, 6080, Bivio, Oberhalbstein, 5827, Castei, in the Averserthal, 6394, snow lies there for six or seven months in the year, and corn will not ripen. The hay-harvest is the great agricultural event of the year, and is so large that great numbers of Italian labourers are annually employed in it. The forests and pastures are the chief source of wealth. The lower Alps maintain a fine breed of cows, the upper are let to Bergamasque shepherds, who drive yearly into the flocks of sheep from North Italy for the summer pastures. There are many mineral springs in the country, the most frequented are at Alvenen, Fuders, Le Prese, and San Vaudenard, besides those in the Engadine (see ENGADINE).

The Grisons is sparsely peopled. The population in 1870 amounted to 91,782,—39,843 Protestants and 51,877

he was appointed on Archbishop Warham's recommendation master or warden of All Hallows' College at Maidstone in Kent, we find him still obliged to bow low from his friends, and even to pledge his plate as a security. He died probably in 1519, and was buried in the collegiate church at Maidstone. With the exception of a few lines of Latin verse, and a letter to Aldus Manutius at the head of Linnæus's translation of Ptolemy's *Sphæra* (Vance, 1499), Grocy has left no literary proof of his scholarship or abilities. He was a great admirer of Aristotle, but his proposal to execute a translation of the philosopher in company with Linnæus and Latimer was never carried out. By Erasmus he has been described as "in severissime castissimæ vitæ, ecclesiasticæ constitutionum observantissimus, peno usque ad suppositionem, scholasticæ theologiæ ad unguem doctus ac natura etiam acerrimi judicii, dum in omni disciplinarum genere exacte versatus" (*Declamationes ad Censuram Facultatis Theologiæ Parisiense*, 1522).

See John Nisbet Johnson, *Life of Thomas Linnæus*, London, 1836; Wood's *Alumni Oxonienses*, Cunningham, *Lives of Eminent Englishmen*, vol. ii, 1833, knight, *Life of Erasmus*.

GRODNO, a western province or government of Russia in Europe, lying between 52° and 54° N lat, 23° and 26° E long, and bounded N by Vilna, E by Minsk, S by Volhynia, and W by the former kingdom of Poland, area 14,901 square miles. The country is a wide plain, in some parts very swampy and covered with large pine forests. Of these that of Bielowicza in the district of Piusbana, comprising a circuit of over 100 miles, deserves notice, for here birches are preserved. The navigable rivers are the Nieman, Bug, Narew, and Bobra. There are also several canals, among which those of Augustow and Ognyski are the most important. The soil, being chiefly alluvial deposit intermixed with sand, is favourable for agriculture and the rearing of cattle and bees. The atmosphere is damp and misty, and the climate in winter is cold. Large quantities of rye, barley, oats, hops, hemp, and flax are raised, but the amount of fruit and vegetables grown is small. The mineral products are insignificant. The manufactures consist of woollen cloths, hats, leather, paper, and spunks, there is also a good export trade in grain, wool, cattle, and timber. Some forty fairs are held annually in the province. Grodno is divided into nine districts, viz., Grodno, Drest, Bielowick, Bielsk, Volkovysk, Kobryn, Piusbana, Slonim, and Sololika. The administration of the whole province is in the hands of a governor appointed by the crown. In 1870 the population was 1,068,521, comprising Lithuanians, Russians, Poles, Tatars, and a few German colonists.

GRODZO, capital of the province of the same name, stands on the right bank of the Nieman in 53° 40' N lat, 23° 50' E long, and is connected by railway with St Petersburg, Moscow, and Warsaw. It is the seat of the provincial government, and contains eight Roman Catholic, a Greek Eastern and two United Greek Catholic churches, a Lutheran chapel, and two Jewish synagogues. The Government office is a splendid edifice. There are two fine palaces erected respectively by Stephen Batory, who died here in 1586, and Augustus III, kings of Poland. Among the other buildings are a public library, a school of medicine, a gymnasium, and several seminaries. The inhabitants (24,789) are engaged in the manufacture of woollens, silks, hats, paper, and the preparation of wax. The fairs are held annually. Grodno was built in the 12th century, and at the commencement of the 13th was annexed to Poland. The Polish diet held there in 1793 ratified the second partition of Poland. Two years later Stanislaus Augustus, the last king, signed his abdication there.

GROEN VAN PRINSTEREE, WILHELM (1801-1876), Dutch statesman, historian, and publicist, was born at Voorburg, on August 21, 1801, received his grammar school

education at the Hague, and studied law, philosophy, and history at the university of Leyden. At the age of twenty-five he published a volume of miscellaneous essays (*Verspreide Geschriften*, 1826), and in 1827 he was appointed private secretary to King William I. From this post he retired in 1833, in order that he might devote himself with less interruption to the historical researches which resulted in the gradual publication of his *Archives ou Correspondance inédite de la Maison d'Orange-Nassau*, in fifteen volumes (Leyden, 1835-64). An ardent conservative in all the ecclesiastical and political questions of the day, he entered the chamber of representatives in 1840, and took part with both tongue and pen in all the more important discussions of the years that followed, especially in those of 1848 and 1849. Between 1849 and 1865 he frequently sat in the second chamber, and from 1850 to 1855 the anti-liberal newspaper *Nederlander* was managed by him. The mortification which European events in 1864 and 1866 had caused him found expression in the occasional writings entitled *La Prusse et les Pays Bas*, *A mes amis à Berlin*, and *Le Rempart Prussien et L'Apocryphe* (1867). Shortly afterwards he withdrew entirely from public affairs, but continued his literary pursuits, his latest production *Memoires et Dernières pensées* being a vindication of the Calvinistic prince as against the Arminian statesman, having been completed (1874) only a short time before his death, which occurred 19th May 1876. Among other works of this author may be mentioned a *Handboek der Geschiedenis van het Vateiland* (1836), and an essay entitled *Ongeloof en Revolutie* (1847), but his sole claim to European celebrity rests upon the *Archives*, with their able if one-sided *Prolegomena*. The letters and documents comprised in the series are of extraordinary interest and value for the whole of the important period which elapsed between the outbreak of the revolution in the Netherlands and the establishment of the commercial oligarchy upon the death of William I.

GRONINGEN, a town of the Netherlands, in the province of the same name, is situated on the Hunze at the mouth of the Aa, 45½ miles in an easterly direction from Halling. The central and more ancient part of the town is still surrounded by the old ditch, and communication is maintained with the outer portions by eighteen bridges. In the centre of the old town lies a group of open places, of which the greatest, the Brede Markt, is one of the most spacious in the Netherlands. Five of the principal streets bear the name of as many ancient families—the Boteringes, the Ebbinges, the Gellings, the Huddings, and the Follings. Among the public buildings of Groningen the town house (Rathuis) is one of the finest. It was built between 1793 and 1810 according to the plans of Jacob Otten Huysen, and was extended in 1873. The administrative offices of the province of Groningen also occupy a fine building, which received a splendid front in 1870-1871. The provincial court of justice, transformed in the middle of the 18th century the corn exchange, dating from 1825, and the weigh-house, completed in 1874, the so called *Ommelandenhuis*, or house formerly devoted to the administration of the surrounding district, the civil and military prison, and the arsenal, are also all worthy of mention. There are twelve churches in Groningen, including two for the Roman Catholics, and five for the Reformed Church of the Netherlands, as well as a Jewish synagogue. St Martin's, the Aa Church, and the New Church (all Reformed) are the principal. Of these the first is a Gothic building founded in 1263, and the last dates from the 17th century. The university of Groningen was founded in 1614, and its buildings were erected in 1847-1850. According to the *Annales Académiques* (Leyden, 1877), the number of the students in 1874 was only 173, the strongest faculty being that of the physical sciences with 57. It has a library, an observatory, botanical

gardens, an antiquarian museum, and a hospital among its auxiliary establishments. A fine deaf and dumb institution, founded by Henri Daniel Gueyot, a gymnasium, a normal college, a school of navigation, a school of design, and a musical school are among the secondary educational establishments. A society *pro erolendo jure patu* has been in existence since 1761, an academy of fine arts was formed in 1830 by the incorporation of two older societies of similar character, and the same year saw the formal establishment of the society for the advancement of natural science, which may be traced back to the association started by Van Swanden in 1801. Groningen maintains a considerable trade, and engages in a variety of industries. It manufactures salt, beer, vinegar, soap, earthenware, and ropes, weaves cotton and woollen stuffs, spins flax, makes brushes, furs, hats, buttons, organs, and pianos, and has a considerable goldsmith and jeweller trade. In 1840 the town and the suburbs comprised a population of 31,782. In 1870 the number of people in the commune, including 1248 on shipboard, was 37,894, and four years later it had increased to 39,284.

Mention is made of the Villa Grounningen in a deed of gift from Henry II to the church of Utrecht in 1040. In 1210 the town was surrounded with walls, but the bishop of Utrecht caused them to be dismantled in 1267, so that the town could again begin to be restored. The compass of the town at this time was about 19,000 feet, received considerable extension in 1469, when the walls were strengthened with six massive towers, and in 1585, when the city was enlarged by the addition of a new district situated on the south side of the Goudeleeuw van 1611-86, and again under William Louis of Nassau between 1608 and 1624. The early history of Grounningen consists mainly of struggles with the bishops of Utrecht, who sought to bring it under their direct control; but that the commercial activity of its population was finding outlet in various directions, and in the 14th it attained to no small importance, is shown by the fact that in 1380 the emperor assigned Groningen to Albert of Saxony, but the citizens preferred to accept the protection of the bishop of Utrecht, and when Albert's son George attempted in 1506 to seize the town, they recognized him as their sovereign lord, and he was obliged to restore to them all the liberties they transferred their allegiance to Duke Charles of Gueldre, and his position was sanctioned in 1516 by the emperor Maximilian I. In 1568 the town joined the United Provinces, and suffered an eventual disaster, sprung from hand to hand, under which all the houses of siege and military occupation, but at least one length, in 1584, it was finally secured for the United Netherlands and remained in their possession until 1648, when it was ceded to France, and the people and the inhabitants of the "Ommelanden," continued how ever, in spite of the decree of the states in 1597, which was intended to set them at rest. In 1673 the town was besieged by the bishop of Munster, and after a long resistance, it was taken, and the French soldiers were implored under Coehorn's direction. The French republicans planted there the tree of liberty in the Giant Market. The French evacuated the town in 1795, and the restoration autonomy was granted in November, 1814. The first constitution of the town was decreed in 1814, and the 18th of January 1874. Among the numerous causes of men of mark who have been natives of Gronningen it is enough to mention the names of the famous astronomer Olaf Struve, and the chemist and Schultze the Orientalists, and Remondin the physiologist.

GRONOVIVS, or GRONOV, JAKOB (1645-1716), was born, of the very great scholars of the 17th century, was born, on the 20th October 1645 at Deventer, where his father, J F F GRONOVIVS (qv), was at that time professor of rhetoric and history. On the completion of his studies at Leyden, where he had early distinguished himself by his powers of intellectual acquisition, he in 1698 visited England, where he became acquainted with Pocock, Pearson, and Moryson, Cassaubo, and where he devoted several months to the collation of rare manuscripts at Oxford and Cambridge. His edition of Polybius, published at Leyden in 1670, in

addition to his own and various notes, contained those which Casaubon to his death had bequeathed to him. Declining an invitation to a Chair at Deventer, he in 1671 visited France, and was brought into intimate relations with D'Haevelot, Theronot, and other distinguished scholars, and after another brief interval at Leyden in 1672 travelled in Spain, whence he passed into Italy. There he accepted from the grand duke of Tuscany a chair at the university of Pisa, which, however, he resigned at the end of two years. Having returned to Deventer by way of Germany, he had settled down with the purpose of working uninterruptedly at an edition of Livy, when in 1679 he was invited by the censors of the university of Leyden to occupy a professorial chair. Here, untamped by several pressing invitations to various foreign universities, he spent the remaining years of his life, in which the calmness which normally characterizes even the most ardent scholarly research was unfortunately too often broken by literary quarrels conducted on his part with excessive violence and acrimony. He died 21st October 1716.

The most celebrated as well as the most important of the works of J. Gionovius is the *Thesauri Antiquitatum Graecarum* (Leyden, 1608-1702, in 18 vols fol., and Veneziæ 1782-1787, also in 18 vols fol.) For this invaluable collection he adopted the plan traced out by Gavinius in the *Thesauri Antiquitatum Romanarum*. Gionovius published new editions of several of the oldest commentaries on the Greek geographers, and also of the *Periplus* of the Red Sea, by Macrobius. Polybius, Tacitus, Ctesio, Ammianus Marcellinus, Quintus Curtius, Suetonius, Ariani, Minutius Felix, Herodotus, Ctesio, and some ancient geographers, the poem of Aristo, on the stars, the *Dactylochoa* of Gollerus, the *Lesson* of Hippocrate, &c. &c. The other productions of Gionovius consist of theses, dissertations, &c. &c. of which a list will be found in the *Dictionnaire* of Gionovius.

GRONOVIVS, or GRONOV, JOHANN FRIEDRICH
(1613-1671), scholar and critic, was born at Hamburg,
20th September 1613. He went through his early studies
with great distinction at Biemen, and afterwards attended
the universities of Leipzig, Jena, and Altorf, whence he
extended his travels into France and Italy. In 1643 he
was appointed professor of rhetoric and history at Deventer,
and in 1658 he succeeded Daniel Heinsius in the Greek
chair at Leyden, where he died on the 28th of December
1671.

Besides editing, with notes, Statius, Plautus, Livy, Pliny, Tacitus, Aulus Gellius, and Seneca's tragedies, he was the author of numerous works which have been exhaustively catalogued by Chassignet and others. They include *De Scaetis libris, sine subsecutione*; *Peenae veteris Graeca et Romana Libri IV* (1643), and notes upon Seneca, Phaedrus, &c., which were subsequently utilized by his son Jacobus Gronovius in his editions of those authors.

GROET, GERHARD (1840-1884), in Latin *Gerardus Magnus*, founder of the society of "Bethmen of the Common Life," was born in Octobea, 1840, at Deventer, where his father held a good civic position. Other forms of the family name are Groote, Groet, and Groetse. He was educated at the University of Utrecht and resided partly at Aix-la-Chapelle and Cologne, Gerhard ("Gerit" or "Geert") in his fifteenth year entered the university of Paris, where he became firmly attached to the nominalism then in vogue, and where he made distinguished progress in almost all the branches of learning then cultivated,—canon law, medicine, astrology, and even magic being studied at the Sorbonne. He was a member of the "Société des Sciences" after his graduation in 1856, he returned to his father's house at Deventer, where, however, his stay was comparatively brief. We next hear of him as learning and teaching in Cologne, according to one account he studied also at Prague, and in 1866 he visited, on public business at it is presumed, the papal court at Avignon. About this time he was appointed to a couple of professorships at Aix-la-Chapelle, and returned to Cologne, and the life of the brilliant young scholar was rapidly becoming luxurious, seelier, and solider, when a great spiritual change passed over him which

resulted in a final renunciation of every worldly enjoyment. This conversion, which took place in 1374, appears to have been due partly to the effects of a dangerous illness, and partly to the influence of the learned and pious prior of the Cistercian monastery at Munsterhuizen near Arnhem, who had seasonally communicated with him on the vanity of his life. During the next five years he devoted a considerable portion of his time to repeated and prolonged visits to the monastery of the Augustinian canons regular at Vrieke Vallis (Gronsdal near Bussela), whose prior, Johann Ruyssbroek, a man of deep though somewhat mystical piety and of considerable literary power, could not fail to impress those who came in contact with him, and many of whose special views are unmistakably reproduced in the writings of Groot and his "fratres devoti." Between 1374 and 1379 Groot had also spent some three years in all at Munsterhuizen in study and prayer, and in the course of the last-mentioned year he left the privacy of the cloister, and having received ordination as a deacon, became a missionary preacher within the diocese of Utrecht. The success which followed his labours, not only in the town of Utrecht itself, but also in Zwolle, Kampen, Leyden, Delft, Gouda, Amsterdam, and many other places, was immense, according to Thomas a Kempis, the people left their business, and their meals to hear his sermons, so that the churches could not hold the crowds that flocked wherever he came. The impartiality of the century, however, which he disavowed, not only against the prevailing sins of the last, but also against the heresy, anarchy, avarice, and impurity of the secular and regular clergy, soon provoked the uncompromising hostility of the entire body of the latter, and accusations of heterodoxy speedily began to be brought against him. It was in vain that Groot emitted a *Publica Protestatio*, in which he declared that Jesus Christ was the great subject of his discourses, that in all of them he believed himself to be in harmony with the Catholic doctrine, and that he willingly subjected them to the candid judgment of the Roman Church. By a skillfully framed episcopal edict of 1383, which excluded from the pulpit all who had not received priest's orders, his public preaching was brought abruptly to an end, an appeal to Urban VI was made in vain. Compelled thus to search for some other field of usefulness, Groot, in conjunction with his friend Florentinus, a canon of Utrecht, began to superintend the labours of certain young men who employed themselves in transcribing manuscripts of church fathers and other authors, from time to time as they met to receive payment for their work, he sought to edify them with religious exhortation. Ultimately the idea suggested itself that the little band might throw their earnings into a common fund and live together according to a fixed rule. The house of Florentinus forthwith became a cloister of "fratres vive communia," who were speedily joined by many new members, both clerical and lay, practised in a considerable variety of handicrafts, the general rule of the Augustinian order was adopted, it was also agreed that their daily bread should be shared in common, and that it should be earned, not begged. Groot's private estate sufficed for the establishment on like principles of a sisterhood who supported themselves by spinning, weaving, and needlework. After a comparatively brief life of singular energy, patience, and self-denial, Groot fell a victim to the plague at Deventer on the 26th of August 1384. Within fifty years of his death the "Bethuim of the Common Life," also called "Fraterne bone voluntate" or "Fraterne Collationari," numbered seventeen collegiate churches in the Netherlands, and contributed somewhat extensively to theological literature. Thomas a Kempis, who wrote a *Vita Gerardi Magni*, was trained under Gerhardt himself at Deventer. The order disappeared at the time of the Reformation.

For a very clear and full account of the life of Groot, with an analytic and exhaustive catalogue of his extant works, reference may be made to the article on the "Bethuim of the Common Life," by Hirsch, in *Illinois's Real Encyclopedia*, ii. 678-696 (1878). The principal original authority is the work of Thomas a Kempis already alluded to. See also Ullmann's *Reformation before the Reformation*, whose somewhat *ex parte* exposition of Groot's theological views, however, must be taken with reservations.

GROS, ANTOINE JEAN, BARON (1771-1835), the pupil of David and the forerunner of Gérardin, occupies a peculiar position between the classic and romantic schools which divided opinion at the beginning of the present century. He was born at Paris in 1771. His father, who was a miniature painter, began seriously to teach him to draw at the early age of six, and showed himself from the first an exacting master. Towards the close of 1785 Gros, by his own choice, entered the studio of David, which he frequented assiduously, continuing at the same time to follow the classes of the Collège Mazarin. The death of his father, whose circumstances had been embarrassed by the Revolution, threw Gros, in 1791, upon his own resources. He now devoted himself wholly to his profession, and completed in 1792 for the *grand prix*, but unsuccessfully. About this time he was, however, on the recommendation of the *École des Beaux Arts*, employed on the execution of portraits of the members of the Convention, and when—disturbed by the development of the Revolution—Gros in 1793 left France for Italy, he supported himself at Genoa by the same means, producing a great quantity of miniatures and *studies*. He visited Florence, but returning to Genoa made the acquaintance of Josephine, and followed her to Milan, where he was well received by her husband. On November 15, 1796, Gros was present with the army near Acolea when Bonaparte planted the tricolor on the bridge. Gros seized on this incident, and showed by his treatment of it that he had found his vocation. Bonaparte at once gave him the post of "inspecteur aux levées," which enabled him to follow the army, and in 1797 nominated him on the commission charged to select the spoils which should enrich the Louvre. In 1799, having escaped from the besieged city of Genoa, Gros made his way to Paris, and in the beginning of 1801 took up his quarters in the Capucins. His "esquisse" (*Musée de Nantes*) of the Battle of Nazareth gained the prize offered in 1802 by the consuls, but was not carried out, owing to it is said to the jealousy of Janet felt by Napoleon, but he indemnified Gros by commissioning him to paint his own visit to the post-houses of Jaffa. The *Pasquades de Jaffa* (Louvre) was followed by the Battle of Aboukir (1806 (Versailles)), and the Battle of Eylau, 1808 (Louvre). These three subjects—the popular leader facing the pestilence unmoved, challenging the splendid instant of victory, heart-sack with the bitter cost of a hard-won field—gave to Gros his chief titles to fame. As long as the military element remained bound up with French national life, Gros received from it a fresh and energetic inspiration which carried him to the very heart of the events which he depicted, but as the army and its general separated from the people, Gros, called on to illustrate episodes representative only of the fulfilment of personal ambition, ceased to find the nourishment necessary to his genius, and the defect of his artistic position became evident. Trained in the sect of the Classicists, he was shackled by their rules, even when—by his naturalistic treatment of types, and appeal to picturesque effect in colour and tone—he seemed to run counter to them. In 1810 his *Madrid* and Napoleon at the Pyramids (Versailles) show that his star had deserted him. His *Francis I* and *Charles V*, 1812 (Louvre), had considerable success, but the decoration of the dome of St Geneviève (begun in 1811 and completed in 1824) is the only work of Gros's later years which

shows his early force and vigour, as well as his skill. The Dupaire of Louis XVIII (Vieville), the Embarkation of Madame d'Angoulême (Beaulieu), the plafond of the Egyptian room in the Louvre, and finally his Hieroglyphs and Diomedes, exhibited in 1835, testify only that Gros's efforts—in accordance with the frequent councils of his old master David—to stem the rising tide of Romanticism served but to damage his once brilliant reputation. Exasperated by criticism and the consciousness of failure, Gros sought refuge in the grosser pleasures of life, but suddenly his vital forces failed him, and on the 25th June 1835 he was found drowned on the shores of the Seine near Sèvres. From a paper which he had placed in his hat it became known that "à la fin de la vie, et après les dernières facultés que lui laissait son talent, il avait voulu se donner la mort." The number of Gros's pupils was very great, and was considerably augmented when, in 1815, David quitting Paris made over his own classes to him. Gros was decorated and named Baron of the Empire by Napoleon, after the Salon of 1808, at which he had exhibited the Battle of Eylau. Under the Restoration he became a member of the Institute, professor at the École des Beaux Arts, and was named Chevalier of the order of St Michel.

M. Deloche gives a brief notice of his life in *Louis David et Son Temps*, and Jules Meyer, *Gros, école des maîtres sans maîtres*. *Mémoires* contains an excellent criticism on his work.

GROSBEAK (French, *Grosbeak*), a name very indefinitely applied to many birds belonging to the families *Prinçillidae* and *Ploceidae* of modern ornithologists, and perhaps to some members of the *Emberizidae* and *Troglodytidae*, but always to birds distinguished by the great size of their bill. Taken alone it is commonly a synonym of *HAWRITON* (*g v*), but a prefix is most usually added to indicate the species, as Pine-Grosbeak, Cardinal-Grosbeak, and the like. By earlier writers the word was generally given as an equivalent of the Linnaean *Lanius*, but that genus, as first established, has been found to include many forms which, according to more recent notions, cannot properly be placed in the same family.

The **PINE-GROSBEEK** (*Pinicola enucleator*) is, with the exception of the Hawfinch just mentioned, the best known species to which the name is applied. It inhabits the conifer-zone of both the Old and the New Worlds, seeking, in Europe and probably elsewhere, a lower latitude as winter approaches—often journeying in large flocks, and straggles have occasionally reached the British Islands, though the records of not more than half a dozen such occurrences can be wholly trusted (Tyrrell, *Br Birds*, ed 4, n pp 177-179). In structure and some of its habits much resembling the Bullfinch (see *Exon*, vol iv p 129), but much exceeding that bird in size, it has the plumage of a Crossbill (vol vi p 614), and appears to undergo exactly the same changes as do the members of the restricted genus *Lanius*—the young being of a dull greenish-grey streaked with brownish-black, the adult being tinged with golden-green, and the cocks glowing with crimson-red on nearly all the body-feathers, this last colour being replaced after moulting in confinement by bright yellow. Nests of this species were found in 1821 by Zettersstedt near Juckajärvi in Swedish Lapland, but little was really known with certainty concerning its nidification until 1856, when the late Mr Wolley, after two years' ineffectual search, succeeded in obtaining in the not very distant district of Munomonska well-entrenched specimens with the eggs, both of which are like exaggerated Bullfinches' The food of this species seems to consist of the seeds and buds of many sorts of trees, though the staple may very possibly be those of some kind of pine. The cock has a clear and pleasing song, which makes him in many countries a favourite cage-bird, and the notes of the hen may even be deemed to qualify her as a musician of no small merit.

Allied to the Pine-Grosbeak are a number of species of smaller size, but its equals in beauty of plumage. These have been referred to several genera, such as *Carpodacus*, *Popassus*, *Bycanetes*, *Uragus*, and others, but possibly *Carpodacus* is sufficient to contain all. Most of them are natives of the Old World, and chiefly of its eastern division, but several inhabit the western portion of North America, and one, *C. guthriei* (of which there seem to be at least two local races), is an especial native of the deserts, or their borders, of Arabia and North Africa, extending even to some of the Canary Islands—a singular modification in the *habitat* of a form which one would be apt to associate exclusively with forest trees, and especially conifers.

The **VIRGINIAN GROSBEEK**, or *Virginian Nightingale* of many writers, *Caulothra virginiana*, next claims notice here, though doubts may be entertained as to the family to which it really belongs. No less remarkable for its bright crimson attire, and the additional embellishment of an elongated crest of the same colour, than for its fine song, it has been an object of attraction almost ever since the settlement of its native country by Europeans. All American ornithologists speak of its easy capture and its ready adaptation to confinement, which for nearly three centuries have helped to make it a popular cage bird on both sides of the Atlantic. The vocal powers possessed by the cock are to some extent shared by the hen, though she is denied the vivid hues of her partner, and her plumage, with exception of the wings and tail, which are of a dull red, is light olive above and brownish-yellow beneath. This species inhabits the eastern parts of the United States southward of 40° N lat., and also occurs in the Bermudas. It is represented in the south-west of North America by other forms that by some writers are deemed species, and in the northern parts of South America by the *C. phoeniceus*, which would really seem entitled to distinction. Another kindred bird, placed from its short and broad bill in a different genus, and known as *Tyr. hirtus* or *viratus* or the Texas Cardinal, is found on the southern borders of the United States and in Mexico, while among North American "Grosbeaks" must also be named the birds belonging to the genera *Guniaca* and *Hedymeles*—the former especially exemplified by the beautiful blue *C. cinerea*, and the latter by the brilliant rose-breasted *H. ludovicianus*, which last extends its range into Canada.

The species of the Old World which, though commonly called "Grosbeaks," certainly belong to the family *Ploceidae*, may be in this work more conveniently treated under the title of **WEAVER-BIRDS** (*g v*) (A 8).

GROSE, FRANCIS (c 1700-1791), a celebrated English antiquary, son of a wealthy Swiss jeweller settled in England, was born at Greenford in Middlesex, about the year 1730. The bias of his mind towards heraldry and antiquities showed itself early, and his father, indulging it, procured him a position in the Herald's College. In 1763, being then Richmond Herald, he sold his tabard, and shortly afterwards became adjutant and paymaster of the Hampshire militia, whereas, as he himself humorously observed, the only account-books he kept were his right and left pockets, into the one of which he received, and from the other of which he paid. This carelessness exposed him to serious losses, and after a vain attempt to repair them by accepting a captaincy in the Surrey militia, the complicity left him by his father being acquainted, he began to turn to account his excellent education and his powers as a draughts-

¹ Many of them are described and beautifully figured in the *Iconographie des Laniens* of the late Prince O L Bonaparte and Pictet-aux-Schlegel (Leyden and Düsseldorf, 1860), a work which includes, how ever, all the Crossbills, Redpolls, and numerous others. The authors, while it excludes many birds that an English writer would have to call "Grosbeaks."

man. In 1757 he had been elected fellow of the Society of Antiquaries. In 1773 he began to publish his *Antiquities of England and Wales*, a work which brought him money as well as fame. This, with its supplementary parts relating to the Channel Islands, was not completed till 1787. In 1789 he set out on an antiquarian tour through Scotland, and in the course of this journey met Burns, who composed in his honour the famous song beginning "Ken ye naught o' Captain Grose," and in that other poem, still more famous, "Hear, land o' cakes, and bither Scots," warned all Scotchmen of this "chield among them taking notes." In 1790 he began to publish the results of what Burns calls "his peregrinations through Scotland," but he had not finished the work when he befooled himself of going over to Ireland and doing for that country what he had already done for Great Britain. About a month after his arrival, however, while in Dublin at the table of his friend Hume, he was seized with an apoplectic fit, and died in a moment, June 12, 1791.

Grose was a sort of antiquarian Falstaff,—at least he possessed in a striking degree the knight's physical peculiarities, but he was a man of true honour and charity, a valuable friend, "overlooking little faults and seeking out greater virtues," and an unmitigated bon companion. His professional merits were lost from contemptible, he was a clever draughtsman, and had considerable powers of poetic composition. While most of his writings concern only the local, other exhibit strong satiric power. But he showed to greatest advantage as a social being, his humour, his varied knowledge, and his good nature were all eminently calculated to make him a favourite in society. As Burns says of him—

But wad ye see him in his glae,
For muckle glee and fun he hae,
Then set him down, and live at ease
Guid fellows are ye him,
And yeot, O yeot! shine thou a wee,
And mair ye'll see him!"

Grose published *The Antiquities of England and Wales*, 6 vols fol., 1778-87. In 1783 appeared *Advice to the Officers of the British Army*, a volume in the manner of Swift's *Drummers to Bed*, which is very consistently attributed to Grose, in 1788, *A Guide to Health, Beauty, Riches, and Honour*, a collection of advertisements of the period, with characteristic satiric touches, in 1788, *A General Dictionary of the Vulgar Tongue*, 8vo, 1788-89, *A Treatise on Ancient Manners and Manners*, in 1789, *Daniel's History of Dogs*, 1789-88, *Military Antiquities*, 2 vols 4to, 1787, *A Poetical Dictionary*, 1788, *Remarks on English Grammar*, 8vo, 1789-91, *The Antiquities of Scotland*, 2 vols 4to, 1791, *Antiquities of Ireland*, 2 vols 4to, edited and partly written by Leitch, *The Grumbler*, sixteen clever humorous essays by Grose appeared in 1791 and 1792, and in 1793 *The Olio*, a collection of essays, jests, and small pieces of poetry, highly characteristic of Grose, though certainly not all by him, was put together from his papers by his publisher, who was also his executor. A capital full length portrait of Grose by Dance is in the first volume of the *Antiquities of England and Wales*, and another is among King's *Portraits*. A detailed sketch of him appeared in the *Gentleman's Magazine*, vol. lvi p. 660. See *Gentleman's Magazine*, vol. lvi pp. 498, 599, *Nobles' Hist. of the College of Arms*, p. 481.

GROSSENHAIN, a town in the circle of Dresden, Saxony, is situated on the Rode, an affluent of the Elbe, 20 miles N W of Dresden. It has manufactures of woollen and cotton stuffs, bookskin, silk thread, and warcloth. The principal buildings are the church of Our Lady completed in 1748, the real school of the second order, the new town-house completed in 1876, the infirmary, and the posthouse. The population in 1875, including the garrison, was 10,686.

Grosenhain owes its origin to the Sorbs, and obtained the rank of a town in the 10th century. It is in fact presided by the Bohemians, by whom it was strongly fortified. It afterwards came into the possession of the counts of Meissen, from whom it was taken in 1313 by the margraves Waldemar and John of Brandenburg. It suffered considerably in all the great German wars, and in 1744 was nearly destroyed by fire.

GROSSETESTE, ROBERT (c. 1175-1553), in some respects the most distinguished of all the English medieval prelates as regards his personal influence both over the men of his time and on its literati, was born of humble parents at Stradbroke in Suffolk about the year 1175. All that is known of his early years is (from his own account) that he studied the characters of the best men in the Scriptures, and endeavoured to conform in his actions to theirs. He was sent by his friends to Oxford, where he studied law and medicine, and seems to have finished his education at Paris, where he probably laid the foundation of his knowledge of Greek and Hebrew. His first patron was William de Vere, bishop of Hereford, to whom he was introduced by Cuthbert Cambricensis, but who died in 1189, and thus had little opportunity of assisting the young scholar. From Paris he returned to Oxford, graduated in divinity, and became master of the schools (*lector scolasticus*) or chancellor. He also became the first rector of the Franciscans at Oxford. Here he probably wrote his commentaries on Aristotle, and laid the foundations of his fame as a preacher. His earliest pretension of which we can speak with certainty was the archdeaconry of Wilts, which he held in 1214 and 1220, he was archdeacon of Northampton in 1221, holding at the same time the prebend of Empingham, which belonged to the archdeaconry. This he exchanged for the archdeaconry of Leicester, which he probably held till 1232. In May 1225 he was collated by Hugh de Wells, bishop of Lincoln, to the church of Abbotsey, Hunts, and at one time he held the rectory of St Margaret's, Leicester. In 1231 he probably wrote his treatise *De Cessionibus Legalium* with the view of converting the Tows, for whose benefit the *Domus conversorum* was established in London this year. A fever in November 1232 induced him to resign all his preferments excepting his Lincoln prebend, and the leisure he thus obtained was spent at Oxford, and probably employed in writing his mathematical treatises and his theological *Diata*. On the death of Bishop Hugh de Walsingham in February 1235, the chapter of Lincoln elected Grosseteste to the see, the election took place on March 27, and he was consecrated at Reading on June 17. His administration of his diocese, then the most extensive in the country, was characterized by great vigour. Within a year of his consecration he visited the monasteries, removing seven abbots and four priors, and in 1238 he issued his constitutions, embodying the points discussed at the great council of the Church of England held in London in 1237, concerning which he had already written to his archdeacons, at the same time, as diocesan of Oxford, he exercised a watchful supervision over the university, protecting the scholars who were in trouble for their attack on the legate Otto in 1235, and even entering into such matters of detail as the place where the university chest should be kept. His energy in his visitations did not pass without opposition, an attempt on his life by poison was made in 1237, from which he recovered with difficulty through the help of John de St Giles, and in 1239 began the quarrel with the chapter of Lincoln, which lasted six years, and was only quelled by the decision of the pope himself. They claimed exemption from episcopal visitation, and spoke of the bishop's demanding what had never from the earliest times been the custom. He would not tolerate an *imperium in imperio*, a body of men joined by common interests, who declined to submit to his jurisdiction, and who might be in need of visitation and correction as much as any others. Full details are given in the bishop's letters of the progress of the quarrel, appeals to Canterbury and the Roman court were followed by excommunications on both sides, the chapter even condescending to exhibit a forged paper as to the history of the church and see of Lincoln. The question was at length settled by a personal appeal to Pope Innocent IV at Lyons. In a

bull of August 25, 1245, he decided almost all the points at issue in favour of the bishop, who lost no time in putting his powers into execution. Of his own view of the matter a very curious exemplification is given in the letter or pamphlet sent to the chapter (quart 127), where his right to visit them is proved by all kinds of mystical arguments and scriptural examples. In 1242, with the help of one Nicholas, a Greek, clerk of the abbey of St Alban's, he translated the *Treatments XII Patris christi*, which had been brought from Athens by John of Beasingtoke. In 1243 occurred the serious quarrel with the chapter of Canterbury (the see being practically vacant, as Boniface was not yet consecrated) respecting the abbey of Badney, — the bishop deposing the abbot in spite of his appeal to Canterbury, and the monks in an especially solemn manner excommunicating the bishop. On receiving the letters from the convent, he threw them on the ground, in spite of the seal containing the effigy of St Thomas, and paid no attention whatever to the sentence. Both parties appealed to the pope, and an arrangement was made between them. In 1244, being one of a committee of twelve chosen to determine what answer should be given to the king's demand of a subsidy, his influence kept the members from being separately won over by the king's endeavours to make parties among them, and the council broke up without giving way to the royal demands. The same year his examination of Robert Passelew, who through the king's influence had been elected bishop of Chichester, though utterly unfit, caused the election to be annulled. On returning from Lyons we find Grosseteste executing various commissions with which he was entrusted by the pope, urging on the archbishop of York the claims of the bishop of Cervia, endorsing and sending round the papal letter allowing Archbishop Boniface the revenues of all benefices in his province that should fall vacant within the next seven years till 10,000 marks should be collected, in order to free the see from its debts, and insisting on the bishops paying the subsidy demanded by the pope, in spite of the king's opposition. In this year (1248) he obtained a bull to prevent any of the Oxford scholars graduating in arts without passing through the usual examinations *secundum morem Parisiensem*, and without having been approved by the bishop himself or one appointed by him. In 1247 he delivered an address vindicating the genuineness of the relic (a portion of our Lord's blood) presented by the king to Westminster. His visitation of his diocese, especially of the monasteries in it, and his superintendence of the studies of Oxford, which went on without interruption during these years, while inducing others of the bishops to follow his example, were not accomplished without serious troubles, embroiling him even with the king. Thus, in 1250, his visitation having proved that many of the religious houses had converted to their own uses certain possessions which belonged to the parishes, which were thus impoverished and left without resident priests, he procured a papal letter authorizing him to revoke what they had thus obtained, citing all the beneficed monks in his diocese to hear the letter. Those who had exemptions appealed to the pope, and Grosseteste again crossed the sea to lay the case before him. But the gulf of the religious orders had been at Lyons before him, and the pope sent him away from his presence in confusion, hopelessly exclaiming against the power of money at the Roman court. He was not, however, downhearted, but busied himself in other affairs, and delivered before the pope and certain cardinals his celebrated sermon on the abuses of the papal court. Here he stayed till the end of September, and then returned in sad plight to England, almost thinking of resigning his see in despair. But he soon recovered from this, and pursued his visitation of the monasteries with still greater vigour, so as to be

accused by Matthew Paris of tyranny such as to make him be thought "not severe, but rather austere and inhuman." In 1251 he was suspended by the pope in consequence of his refusing to admit an Italian ignorant of English to such benefice in his diocese. The suspension was short, as he officiated at Ely this year, on the dedication of the church founded by Richard of Cornwall, his position among the bishops being shown by his celebrating mass at the high altar. In 1252 he obtained a papal letter authorizing the appointment of vicars, and their payment out of the revenues of their livings, and in the same year his influence kept the bishops together in their resistance to the royal demands of a tenth of church revenues for three years granted by the pope, nominally for the king's necessities on his intended crusade. He had also this year a calculation made of the revenues of the townships in England, which amounted to more than 70,000 marks. In 1253 the pope ordered him to induce by provision his nephew Frederick di Lavagna into a canonry at Lincoln, the bishop's answer to the requisition sent to the papal commissioners (the archdeacon of Canterbury, and Innocent, the pope's notary), though of less importance than many of his other letters, has done more to make his fame popular and permanent than any of his works. He is very decided in refusing to institute the candidate from his unfitness, at the same time that he expresses the utmost reverence for the pope and the Roman see. The letter made the pope very angry, and he was only quieted by the advice of the cardinals, who spoke in the highest terms of the bishop's character and position. Grosseteste was present at the parliament in May, when the violators of Magna Charta were again excommunicated, not content with this, he had the sentence read in every parish in the diocese of Lincoln. In October he fell ill at his manor of Buckden, where he died on October 9th. He was buried on October 13th in Lincoln Cathedral, the archbishop performing the service and many other bishops assisting. Bells were said to have been heard in the air on the night of his death, and miracles to have taken place at his tomb. The pope is said to have expressed joy at his death, and to have desired to have his bones cast out of the church. This story of the pope's dream, that the bishop appeared to him and struck him in such a manner as to cause his death, shows what the popular estimation of the two was. It is perhaps not to be wondered at that the attempt to procure the canonization of the bishop in 1807 failed.

How great the personal influence of Bishop Grosseteste was may be chiefly learnt from his letters: he was the instructor of the king (e.g., in one of his letters on the value of the royal anointing), the friend of the queen, the tutor of Simon de Montfort's sons, his warmer and cooler at different times, the correspondent of Adam de Marisco, the refuge of many as to spiritual difficulties. Of those who speak of him, one is especially struck by his courage, another by his universal knowledge, a third by his subtlety in interpreting scripture, a fourth by his frequent preaching. Even Matthew Paris, no favourable judge, warns into admiration in speaking of his character (*Chron. Maj.* v. p. 408). The popularity of Grosseteste as an author is proved by the number of manuscripts remaining of his works, and from the fact that very few writers for the two centuries following his death do not contain quotations from *Lancelotus*. His determination to root out all abuses is seen in his opposition to unjust demands of the king or the archbishop, to unfit nominees of the pope, indeed to the whole system of papal pretensions. That he was of a hasty temper, and harsh and severe at times, is true, but no one ever more thoroughly tried to do his duty, probably few have effected more.

equivalent to "great," is the same as that of Hugo Grotius, with whom the Grote would gladly have traced a relationship, but the evidence was wanting. George Grote's grandfather, Andreas (born in 1710), a merchant of Bremen, removed to England, and after some years of successful business joined Mr George Prescott in founding the banking house of "Grote, Prescott, & Company" (January 1, 1766). He was married twice. His eldest son by his second marriage, George (born in 1762), was married (in 1793) to Selina, daughter of the Rev Dr Peckwell, one of the countesses of Huntingdon's chaplains, whose portrait is preserved in the vestry of the chapel at Chichester, where he ministered. Dr Peckwell was descended on the mother's side from the French Protestant family of De Bloyet, who had left Touraine in consequence of the revocation of the edict of Nantes, and thus the husband, who was the son of George Grote and Selina Peckwell, had a share of that Huguenot blood which has been a rich source of intellectual as well as industrial life in England.

Like many other eminent men, George Grote owed much of his future intellectual greatness to his mother's careful training. Having a strong desire to see her son excel in learning, she taught him reading and writing herself, and even grounded him in the elements of Latin before he was sent to the grammar school at Sevenoaks, in his sixth year (1800). The four years spent there gave an earnest of his whole future life. In the language of his biographer, who has lately attained the end of a life inseparably interwoven with his, "he evinced a decided aptitude for study, being rarely found belinched with his tasks, and working habitually above boys of his age in the class to which he belonged." In his tenth year he was removed to the Chichester house, the headmaster of which, Dr Raine, had the honour of training, along with George Grote, Connop Thirlwall, Dean Waddington and his brother Horace, Sir Cresswell Cresswell, Sir Henry Halliwell, and other men of future distinction. Grote was not allowed to share the courses of most of his schoolfellows at a university, but this great privation was turned into a pre eminent distinction by the resolution with which his own strong will and untiring industry supplied the loss. The supposed advantage of an early application to business led the father to take George into the bank at the age of sixteen. But his six years at the Chichester house had not only imbued him with a strong taste for classical learning, but had supplied him with that motive to high culture, which forms the most convincing argument in its favour, and to which he remained faithful through a half century of educational disputes and heresies. It was not as an alternative to a life of business, but as its proper complement, that he chose and advocated ancient learning. "Looking for ward," says his biographer, "to a commercial course of life, certain to prove uninteresting in itself, he resolved to provide for himself the higher resources of intellectual occupation." Engaged in the bank throughout the day, he devoted his early mornings and evenings to a systematic course of reading, of which the chief subjects were the ancient classics, history, metaphysics, and political economy, to the last of which he was attracted by the writings of David Ricardo, whose personal acquaintance he formed in 1817. To these studies he added the learning of German by the aid of a Lutheran clergyman, which, together with his knowledge of French and Italian, placed the stores of Continental scholarship within his reach. His chief recreation was music, and he learned to play the violoncello, to accompany his mother, who was a fine musician. Arrived at the age of manhood (in the winter of 1814-1815), he formed the acquaintance of the young lady who afterwards became his wife, devoted to and worthy of him, the very complement of his life, intellectual as well as social, and finally his biographer in a spirit of loving but

not indiscriminate admiration. This was Miss Harriet Lewin, the daughter of Mr Thomas Lewin, of Dolevay, in Kent, a gentleman of old family and independent fortune. She was born at Southampton, July 1, 1762, and was consequently nearly two years older than Grote. From causes which need not be related here their intimacy was suspended for three years, during which Grote's studies made steady progress. To this period belongs his earliest literary composition, an essay on his favourite Lucretius, which still exists in MS. His letters also record the careful study of Aristotle, his final estimate of whom formed his last unfinished work. But the most interesting light is thrown on the method and course of his studies in the diary which he kept for Miss Lewin's information. This record bears witness, not only to the wide diversity of his studies in ancient and modern literature, philosophy, and political economy, but also to the fact that he read the authors themselves whom he wished to know,—read them as a whole, instead of merely reading what others had written about them.

An epoch, perhaps the most critical turning point of Grote's intellectual life, was formed by his introduction, through David Ricardo, to James Mill, who was then composing his metaphysical work entitled *An Analysis of the Human Mind*. Already attracted to this study, Grote became Mill's admiring disciple in mental and political philosophy. From this time he adopted the broad principles, from which he never receded, of experience as the source of all knowledge, and utility as the foundation of morals. The views derived from Mill were confirmed by the teaching of Jeremy Bentham, and by intercourse with a band of young disciples, over whom the two philosophers wielded an unbounded influence. Among these John Stuart Mill began now to make his appearance as a boy of twelve years old. It is important to note the influence which the study of metaphysics exercised upon the development of Grote's intellectual character. To the general public he is chiefly known as an historian, but he was equally distinguished as a metaphysical philosopher. To the teaching of James Mill may also be traced his democratic principles and his zeal for freedom of thought, hardening into intolerance of all religious systems and their ministers. But, however, they may have determined his course upon certain occasions, these antipathies never struck their root down into the real soil of his gentle and conscious nature.

In 1820, at the age of twenty-four, he was married to Miss Harriet Lewin. They lived at first at the banking house in Threadneedle Street. The confined situation soon told on Miss Grote's health, and the death of her only child, a week after its birth, was followed by a dangerous illness. It was at her bedside at Hampstead, during his slow recovery, that Grote composed the first work he published, an *Essay on Parliamentary Reform*, in reply to an article by Sir James Mackintosh in the *Edinburgh Review*, No 61 (1821). The pamphlet is a vigorous assertion of the broadest principles of popular representation, in opposition to a scheme of class representation sketched by the reviewer. It proclaimed Grote's adherence to those political views held by the party afterwards called the "philosophical radicals," and it strongly pleaded for the vote by ballot, of which he afterwards became the parliamentary advocate. The most important parts of this pamphlet were embodied in his later essay on the *Essentials of Parliamentary Reform* (1831), reprinted in his *Miscellaneous Works*. In April 1832 Grote sent a vigorous letter to the *Morning Chronicle* in reply to Canning's speech against Lord John Russell's motion for reform. In the same year he spent much time upon some MSS of Jeremy Bentham, which the aged philosopher entrusted to his young disciple to put into a readable form. After carefully digesting and

arranging them, he published them anonymously in a small 8vo volume, entitled *Analysis of the Influence of Natural Religion on the Temporal Happiness, or Misconduct, by Philip Beauchamp*. Meanwhile the quiet course of life went on in the Calverley Street. The scanty leisure of each day was devoted to the joint studies of husband and wife, for "Mr. George Grote was industriously studious, after his fashion, under the direction of her husband, who laid great stress upon her cultivating the attentive vein of instruction—above all, logic, metaphysics, and politics, and she accordingly strove to win him these subjects, out of deference to his wish, and in order to qualify herself to be associated with his intellectual labours as time wore on." Then pleasures were likewise in common, the wife, who was an accomplished musician, learnt the violoncello to accompany her husband, but he dropped his music in 1830. A circle of congenial minds frequented the house in Thackeray Street from 1822 to 1830. Within that choice society there was a narrower circle of students, who met there twice a week at half past eight in the morning for an hour or two's reading. Among others were John Stuart Mill, Charles Bulbin, and John Arthur Roebuck. They read the most recent works on metaphysics and kindred subjects in the light of their adored teachers, Bentham and James Mill, beyond whom they believed all to be in Christian darkness.

The year 1823 marks the epoch of the first conception of Grote's great work, and an extant letter shows the spirit in which he approached it. On January 14th he writes—"I am at present engaged in the fabulous ages of Greece, which I find will be required to be illustrated by bringing together a large mass of analogous matter from other early histories, in order to show the entire uncertainty and worthlessness of tales to which early associations have so long familiarized all classical minds. I am quite amazed to discover the extraordinary goodness and facility with which men assert, believe, reassert, and re-believe. The weakness appears to be next to universal, and I really think that one ought to write on the walls of one's dressing-room the caution of the poet Epicharmus—

Ἥβη, καὶ μὴ μὲν ἀνέστης, ἔκπλην ταῖς τὰν ὀφθαλμῶν

The subject ever presents to his thoughts; came up so often in the discussions with his friends as to suggest to his wife's sympathy and ambition for his fame the definite work of his future life. One day she said to him—"You are always studying the ancient authors whenever you have a moment's leisure, now here would be a fine subject for you to treat. Suppose you try your hand!" "The idea," she adds, "proved acceptable to the young student, and, after reflecting for some time, he came to the resolution of entering upon the work."

Henceforth this definite aim prevailed amidst the still wide range of reading which threw new light from all quarters upon the central object, and the mass of notes and extracts still preserved attest the diligence with which he prepared for it. Happily for himself and for the world, he was diverted from the work till he could resume it, not only with that clearer mental perspective in which a long meditated object appears when we return to it afresh, but with the enlarged experience of nearly twenty years occupied in practical politics and converse with statesmen, abroad as well as at home. Meanwhile he gave the world an earnest of his work in an exhaustive review of Mitford's *History of Greece* in the *Westminster Review* for April 1826,—one result of which was a letter from Niebuhr, clearly designating Grote as the historian of Greece, and trying him to a visit which events never permitted him to pay.

From 1825 to 1827 Grote took part in the scheme of founding the "University of London" in Gower Street, with the management of which institution he became after-

wards intimately connected. As the political crisis of 1830 approached, public and private events conspired to draw Grote into the vortex of politics. The failure of his father's health gave him a new position in the bank, and in the spring of 1830 he was able to arrange for a visit to the Continent, which brought him into connexion with the liberal politicians of Paris on the eve of the revolution. An interesting record of the state of affairs and of the impressions of this visit are preserved in Mrs. Grote's *Life of Amy Schlegel*, published in 1860. The travellers were recalled in June by the illness of Grote's father, who died before their arrival at the age of 70.

Thus, in his 36th year, George Grote, now the head of the family, found himself master of his own affairs, and of about £40,000 personal property, besides the family estates in Lincolnshire and Oxfordshire. His business and studies alike led him to fix his residence in London, and the first use he made of his wealth was to subscribe £500 to the revolutionary committee of the Hôtel de Ville, with an offer to come himself to Paris if his presence would be of any use. The pressure of business as his father's executor kept him, in spite of strong solicitations, out of any active part in the agitation for reform, but did not prevent the steady progress of the *History*, which Mrs. Grote writes (February 1, 1831), "must be given to the public before he can embark in any active scheme of a political kind." He refused an invitation to stand for the city in 1831, but he made an able contribution to the argument in a statement of the *Essentials of Parliamentary Reform*, published this year, to which reference has already been made. His reluctance to enter parliament was overcome after the passing of the Reform Act in 1832, and, being returned at the head of the poll, he appeared as one of the members for the city of London in the first reformed parliament, which met on February 4, 1833. He at once gave notice of a motion for the vote by ballot in parliamentary elections, which he brought before the house on the 25th of April following. His speech on that occasion was prepared with great care, and displayed that cogent reason and calm earnest eloquence which marked all his efforts in debate. The substance of the argument, and a notice of his principal speeches in parliament, will be found in Professor Bain's sketch of his character and writings prefixed to his "minor works." Earnest as were his political convictions, and faithfully as he discharged the duties which he had undertaken, Grote's parliamentary career forms only an episode in his life, but an episode which contributed to refresh and qualify him for his main work. He sat in three successive parliaments, from 1833 to 1841, witnessing the gradual passage from the first triumph of reform to the Conservative reaction under Sir Robert Peel, and the steady decay of his own sect of philosophic radicalism, which never had a root in popular opinion. He was returned the last time by a bare majority of six, and his party numbered just the same figure. Charles Bulbin said to him one evening "I see what we are coming to, Grote, in no very long time from this, you and I shall be left to 'tell' Moleworth."

During the eight years and a half of his parliamentary life, Grote kept up his varied reading, and formed a growing desire for a knowledge of physical science. But the staff of his mental diet, and his refuge from all meaner objects of thought, was still the same. In the weary intervals of attendance on parliament a Tauchnitz copy of Plato was ready in his pocket, and when snored up in the country during the vacation he writes—"A Greek hook is the only refuge." His hospitalities expanded with his social position, and among his new friendships the one he most valued was that formed in 1835 with Mr. (afterwards Sir) George Cornewall Lewis, the letters exchanged with whom on various points in classics and philosophy enrich

this narrative of his *Life*. Among the other objects of his literary interest at that time was Sir William Moksforth's collected edition of the works of Hobbes, dedicated to Grote, whose review of the first two volumes in the *Spectator* (1839) is reprinted among the *Minor Works*.

During the whole period of Whig decay, and especially from the beginning of the present reign, Grote felt a declining interest in politics, and accordingly, on the dissolution in June 1841, he determined to retire from parliament. Thus at the age of forty-six he was yet free to spend the remaining thirty years of his life in the work long prepared and contemplated. In half that period the *History of Greece* was finished, the remaining half was devoted to the two works on *Plato* and *Aristotle*, which made up the Hellenic "trilogy" of his life-long studies.

After a six months' holiday (1841-1842) for the long desired purpose of visiting Italy and studying the antiquities of Rome upon the spot, he returned to his business at the bank, and set vigorously to work on the new plan for the first two volumes of his *History*—repeating the authorities, revising his notes, and rewriting the whole. The greater part of these two volumes was occupied with the first division of his subject, which was now for the first time severed from actual history, and placed in its proper mythical light, under the title of "Legendary Greece." The closing months of 1842 were employed in sending forth a sort of "funeral vessel" in the form of a review of Niebuhr's *Griechische Historie-Geschichte*, which appeared in the *Westminster Review* (May 1843) under the title of "Grecian Legends and Early History," and is reprinted in the *Minor Works*. His biographer states that, "this article, wherein the collected Grote of Grote's long and assiduous studies on the subject found a vent, was written with uncommon zest, and he anticipated with lively curiosity the effect it would produce over the learned world." It was received as a striking promise of the new light in which he was about to place the primeval ages of Grecian history. It is important to record an incidental remark, which shows that, amidst his uncompromising severance of legend from real history, Grote adhered to the great principle avowed alike by Herodotus and by Bode: "An historian is bound to produce the materials upon which he builds, be they never so fantastic, absurd, or incredible."

With the beginning of 1843, exactly ten years after the interruption caused by his entrance into parliament, the composition of the first volume for the press was vigorously begun, and at midsummer he further cleared his path by retiring from the banking-house of Prescott, Grote, & Company. While still at work upon the *History*, he published in the *Classical Museum* (1843) an important essay on ancient weights and measures, reviewing Roschke's *Metrische Untersuchungen*, which is reprinted among his *Minor Works*.

The first two volumes of the *History* were completed early in 1845, and published in March 1846. Their reception is well known, and the effect of their success upon Grote himself was thoroughly characteristic of the man—"From all sides congratulation and eulogy flowed in upon the author, inasmuch that he himself now began to feel something like confidence in the success of his long-drawn work. Thus I became" (writes Mrs Grote) "for once witness of a state of feeling on his part approaching to gratified self-love, which at times would pierce through that imperishable veil of modesty habitually present with him." The first volume and nearly half of the second are occupied with "Legendary Greece," the latter half of the second volume begins "Historical Greece," and consequently contains only a small portion of the real history. These volumes were reviewed with great praise by John Stuart Mill in the *Edinburgh Review*, and by Dean Milman in the *Quarterly Review*.

The success of the first two volumes incited Grote to prosecute the work with indefatigable industry, and such progress had been already made that the third and fourth volumes, bringing the narrative down to the battle of Marathon, and containing an account of Grecian poetry and philosophy in its earliest stages, appeared in the following year (1847). Two more volumes, the fifth and sixth, coming down to the eleventh year of the Peloponnesian war, were published in 1849. These two volumes, together with the two preceding ones, were reviewed in the *Edinburgh Review* by Sir George Cornewall Lewis. The seventh and eighth volumes, which brought the Peloponnesian war to the end, and which contained the thrilling and original view of the Sophists and of Socrates, appeared in 1850. Two articles in the *Quarterly Review* upon this portion of the work, one upon the history, and the other upon Socrates and the Sophists, were written by Dean Stanley. The ninth and tenth volumes were published in 1853, the eleventh in 1853, and the last and twelfth in 1856, just ten years after the appearance of the first two volumes. The work closes with the generation contemporary with Alexander the Great, "an epoch," the historian observes, "from whence dates not only the extinction of Grecian political freedom and self-action, but also the decay of productive genius, and the desolament of that consummate literary and rhetorical excellence which the 4th century B.C. had seen exhibited in Plato and Demosthenes."

The peculiar merits of Grote as an historian are discussed at length by the writer of the present notice in a review of the whole work in the *Quarterly Review* in 1856. It is sufficient to state here that the quality in which he surpassed all his predecessors in Grecian history, and which achieved for him a success that can never be undone or superseded, lies in his placing his whole subject in the full light of historic truth apart from partial judgments, looking at the actions of men from their own points of view and not only from ours, and having constant regard to those ethical principles of human nature which his twofold training as a philosopher and politician qualified him to estimate. Many of his details may be disproved and his judgments reversed, but his work will last for ever. The opinion of scholars may be summed up in Bishop Thirlwall's "hearty congratulations on the completion of this glorious monument of learning, genius, and thought, to which I believe no other literature can exhibit a parallel."

An episode during the progress of the *History* is characteristic of the wide range of political observation which Grote brought to bear upon his work. In the Swiss discussions during 1847, which led to the war of the "Sonderbund," he saw so close a resemblance to the conflicts of the Greek republics that he resolved to study the question on the spot. His *Lettres* on the subject, which originally appeared in the *Spectator* newspaper, were collected into a volume, which was reprinted in 1876 by Mrs Grote, with the addition of a letter written by him to M. de Tocqueville after the termination of the war.

On the completion of the *History*, Grote contributed to the *Edinburgh Review* (1856) a criticism of Sir George Cornewall Lewis's *Enquiry into the Credibility of the early Roman History*, which is reprinted in his *Minor Works*, a most interesting study of the points in which the two scholars agreed and differed, Grote stopping short of his friend's scepticism in some cases.

After a well-earned holiday on the Continent in the summer of 1856, Grote set steadily to work upon his *Plato*, which occupied him nine years, and appeared in 1865 in three volumes 8vo, under the title of *Plato and the other Companions of Sokrates*, when the author had completed his

seventieth year. This work, he remarks, was "intended as a sequel and supplement to his *History of Greece*." After giving an exhaustive review of early Greek philosophy, from Thales to Democritus, and an account of the life of Plato, of the Platonic Canon, and of Platonic compositions generally, he analyses at great length each of the dialogues, with illustrative remarks, unfolding a number of his own philosophical views. The work concludes with two chapters, one on the "Other Companions of Socrates," and another on "Xenophon."

On the completion of this work, Grote wrote in the *Westminster Review* (1856) an elaborate criticism of John Stuart Mill's *Examination of Sir William Hamilton's Philosophy*. "At the same time, though in his seventy-first year, he set to work upon Aristotle, hopeful in the continuance of those powers which he thus described three years later:—"My power of doing work is sadly diminished as to quantity, as my physical powers in walking are, but as to quality (both perspicacity, memory, and suggestive association bringing up new communications), I am sure that my intellect is as good as it ever was, and all who knew him well can attest the accuracy of this judgment. But he did not live to complete the third portion of his "trilogy," though he had been studying the Aristotelian treatises from his earliest manhood. The fragment of his Aristotelian labours was published in 1872, the year after his death, in two volumes, edited by Professors Bain and Robertson. Besides the life of Aristotle and the canon of his works, these volumes are chiefly occupied with an examination of the logical treatises of the great philosopher, but the editors have been able to give, from the MSS of the author and from the contributions which he made to Professor Bain's *Manual of Mental and Moral Science*, some account of Aristotle's other works. There are also two valuable essays on the ethics and politics of Aristotle, found among the author's MSS after the publication of Aristotle, which were printed in 1870 in the *Fragments on Ethical Subjects by the late George Grote*.

During the composition of the Plato and the Aristotle Grote resided in London, at 12 Savile Row, and in two country houses, which he occupied in succession, first at Butlow Green in Kent from 1859 to 1863 (where Jeremy Bentham had once lived), and afterwards at Shere among the Surrey hills, in which places his day was divided between regular work, exercise as regular, and the society of congenial friends. Many a work of social duty and benevolence found prompt performance, and he paid unremitting attention to the business of his three favourite institutions—the University of London, University College, and the British Museum, of which last he became a trustee on the death of Henry Hallam in 1860. But his connexion with the two former bodies was so close, and he made them administration so completely the chief business of his life after his literary works, that a few words upon the subject are necessary.

It has been already mentioned that he took an active part in the foundation of the university of London in Cowes Street. He was a member of the original council of that institution from 1837 to 1881, from which he retired upon entering parliament. This institution exchanged its name for that of "University College" before the foundation in 1856 of the "University of London," which now conducts its business in Burlington House. Grote joined again the council of University College in 1849, and from that time till his death he took a leading part in the administration of its affairs. He became treasurer in 1860, and president in 1868, on the death of Lord Brougham. Grote was one of the seven new members added by the crown to the senate of the "University of London" in 1860. From 1862, when he was elected vice-chancellor, on the

resignation of Sir John Slaw Lewtiev, he became the leading spirit of the university.

In both University College and the university of London he was the constant advocate of the threefold cord of knowledge—literature, philosophy, science,—which he held to be united by tampering with any one of them,—earnestly upholding what he regarded as sound metaphysics, supporting the establishment of degrees in science, and opposing, to the last of his life and strength, the omission of Greek from the examination for matriculation. He left his library to the university, and he showed his attachment to the college and to metaphysical studies by bequeathing to it a sum of £6000 for the endowment of a professorship of mental philosophy. He continued to labour in the discharge of his duties to these institutions, even when fast gone in the malady which appeared in 1870, and carried him off on the 18th of June 1871, in his seventy-seventh year. He found his fitting resting place in Westminster Abbey, just beneath Camden's monument, and near Macaulay's grave. His portrait by Mr. Millais, taken the year before his death, is preserved in the senate-room of the university of London.

Grote's great literary merits received due and fitting acknowledgment from his contemporaries. He was elected a member of the Royal Society, received from the university of Oxford the honorary degree of D.C.L., and from that of Cambridge the honorary degree of LL.D., was made a foreign member of the French Institute in the place of Macaulay, and lastly was offered a peerage by Mr. Gladstone in 1869, an honour which he declined. His personal character cannot be better described than in the words of his friend Professor Bain—"In the depths of his character there was a fund of sympathy, generosity, and self denial rarely equalled among men, on the exterior, his courtesy, affability, and delicate consideration for the feelings of others were indelibly impressed upon every beholder, yet this amiability of demeanour was never used to mislead, and in no case relaxed his determination for what he thought right. Fervent and exact in his engagements, he inspired a degree of confidence and respect which did most beneficially on all the institutions and trusts that he took a share in administering, and his loss to them was a positive calamity."

The authorities for Grote's life are—*The Personal Life of George Grote*, by Mrs. Grote, 1873, and the *Critical Remarks on his Intellectual Character, His Works, and Speeches* (770 p. pp.), by Prof. van Buren, prefixed to *Grote's Works*, 1874, 1875.

The following is a list of Grote's works, most of which have been noticed in the course of the preceding mention:—*A History of Greece*, in 12 vols. 8vo, 1816-1826, republished in 1862 in 8 vols. 8vo, in 1869 in 13 vols. 12mo, and lately in 1871 in 19 vols. 8vo, *Plato and the Other Companions of Socrates*, in 2 vols. 8vo, 1865, republished in the same form in 1867, and a third time in 1871, *Aristotle*, edited by Alexander Bain and G. Croom Robertson, 2 vols. 8vo, 1872, *The Athenian Works of George Grote*, edited by Professor Bain, 1871, containing—(1) "Essentials of Parliamentary Reform," (2) "Notes of Sir William Molesworth's edition of the Works of Hobbes," (3) "Grecian Legends and Early History," (4) "Review of Beck on Ancient Weights, Coins, and Measures," (5) "The Mental Address in commemoration of the twenty-first Anniversary of the London Scientific Institution," (6) "Address on delivering the present University College," (7) "Review of Sir C. Lewis on the Credibility of Early Roman History," (8) "Platonic Institute respecting the Relation of the Truth and Aristotle's Communion with Doctrines," (9) "Review of John Stuart Mill on the Philosophy of Sir William Hamilton," (10) "Papers on Philosophy," *Seven Letters concerning the Politics of Sparta*, printed by the *Outlook of the Grand Hall* in 1837, 1857, republished in 1876, with the addition of an unpublished letter written by the author to M. de Tocqueville shortly after the termination of the war, *Fragments on Ethical Subjects*, 1870 (a selection from his posthumous papers).

Mrs. Grote survived her husband upwards of seven years, and died on the 26th of December 1878, at her residence in Shere. She was one of the most remarkable

English-women of the present century. Endowed in youth with great personal beauty, which matured into a grand expression and noble presence in advanced age, she possessed intellectual powers of the highest order, combined with a lofty sense of duty and the strictest regard to truth. The chief events of her life have been already related in the preceding notice of her husband. Her own writings, besides the biography of Mr Grote, are *A Memoir of the Life of An Scherffer* (1860), and *Collected Papers (original and printed) on Poesie and Verse* (1863), of which the most important are a "Review of M. Lavigne's Essay on the Mutual Economy of England," "Case of the Poet against the Rich correctly stated," a "Review of Thomas Moore's Life and Works," and the "History of East Dindham." But though she wrote lucidly and powerfully, it has been well observed by one of her friends that "her writings fail to give a just idea of the irresistible fascination of her conversation. That she never succeeded in fully transmitting to paper, and it remains a thing of unapproachable excellence and tender memory, only understood by those to whom it offered the highest mental enjoyment" (W. SM.).

GROTEFEND, GEORG FRIEDRICH (1778-1853), to whose persistence and ingenuity the decipherment of the cuneiform inscriptions originally due, was born at Münden in Hanover, June 9, 1778. He was educated partly in his native town, partly at Hild, where he remained till 1793, when he entered the university of Göttingen, and there became the friend of Heyne, Tychoen, and Heeren. Heyne's recommendation procured for him an assistant tutorship in the Göttingen gymnasium in 1797. While there he published his work *De Pausaniasive sine Scriptura Universale* (1799), which first brought him into notice, and led to his appointment in 1803 as professor of the gymnastics of Frankfurt-on-the-Main, and shortly afterwards as professor. Grotefend was best known during his lifetime as a Latin and Italian philologist, though the attention he paid to his own language is shown by his *Anfangsgründe der deutschen Poesie*, published in 1816, and his foundation of a society for investigating the German tongue in 1817. In 1821 he became director of the gymnasium at Hanover, a post which he retained till his retirement in 1849, four years before his death. In 1823-4 appeared his revised edition of Wenzel's Latin grammar, in two volumes, followed by a similar grammar for the use of schools in 1826, in 1835-8 a systematic attempt to explain the fragmentary remains of the Umbrian dialect, entitled *Reste der Etruskischen Sprache* (Umbrian *ex Inscriptionibus antiques enodatis* in eight parts), and in 1839 a volume of similar character upon Oscean (*Reste der Etruskischen Sprache*). In the same year he published an important memoir on the coins of Bactria, under the name of *Die Münzen der griechischen, parthischen, und indoskythischen Könige von Bactrien und den Ländern am Indus*. He soon, however, returned to his favourite subject, and brought out a work in five parts, *Zur Geographie und Geschichte von Altitalien* (1840-3). Previously, in 1836, he had written a preface to Wagenfeld's translation of the spurious *Stachmarchian* of Pseudo-Byzantium, which professed to have been discovered in the preceding year in the Portuguese convent of Santa Maria de Matinhao. But it was in the East rather than in the West that Grotefend did the work which has given him a lasting name. The mysterious cuneiform inscriptions of Persia had for some time been attracting attention in Europe, exact copies of them had been published by the elder Niebuhr, who lost his eyesight over the work, and Grotefend's friend, Tychoen of Rostock, believed that he had ascertained the characters in the column now known to be Persian to be alphabetic. At this point Grotefend took the matter up. His first discovery was communicated to the Royal Society of Göttingen in 1800, and reviewed by Tychoen two years

afterwards. In 1815 he gave an account of it in Heeren's great work on ancient history, and in 1837 published his *Neue Beiträge zur Erläuterung der persisch-altiranischen Keilschrift*. Three years later appeared his *Neue Beiträge zur Erläuterung der babylonischen Keilschrift*. His discovery may be summed up as follows—(1) that the Persian inscriptions contain three different forms of cuneiform writing, so that the decipherment of the one would give the key to the decipherment of the others, (2) that the characters of the Persian column are alphabetic and not syllabic, (3) that they must be read from left to right, (4) that the alphabet consists of forty letters, including signs for long and short vowels, and (5) that the Persian inscriptions are written in Zend (which, however, is not the case), and must be ascribed to the age of the Achaemenian princes. The process whereby Grotefend arrived at these conclusions is a prominent illustration of persevering genius. History made it clear that the monuments to which the inscriptions were attached belonged to Cyrus and his successors, whose names ought accordingly to be found in them. By a comparison of texts Grotefend determined the groups of characters by which these names were expressed, and by further observing what characters were common to the several groups, and of how many characters each group consisted, he was able to assign the conjoined values of D U S N D U S C I T to D A I U S, the letters of a frequently recurring one. The native pronunciation of Darius was furnished by Strabo and the Old Testament. The names of Xerxes and Artaxerxes were next deciphered, and the phonetic power of a good many characters was thus ascertained. The correctness of the decipherment was verified, not only by the fact that the right letters were always found in the right places in each name, but also by the discovery that the word which invariably followed each name, and therefore presumably meant "king," when read by the new alphabet, presented the same form as the Zend term for "monarch." It was clear that a solid basis had been laid for the interpretation of the Persian inscriptions, and all that remained was to work out the results of Grotefend's brilliant discovery, a task ably performed by Burnouf, Lassen, and Rawlinson. Grotefend died the 15th of December 1853.

GROTIUS, HUGO (1583-1645), in his native country Hug van Groot, but known to the rest of Europe by the Latinized form of the name, was one of the famous men of the 17th century, almost equally eminent in public services and as a writer. He was born at Delft on Easter day, 10th April 1583. The Groot was a branch of a family of distinction, which had been noble in France, but had removed to the Low Countries more than a century before. Thon French name was De Combet, and this cadet branch had taken the name of Groot on the marriage of Hugo's great-grandfather with a Dutch heiress. The father of Hugo was a lawyer in considerable practice, who had four times served the office of burgomaster of Leyden, and was one of the three curators of the university of that place.

In the annals of precocious genius there is no greater prodigy on record than Hugo Grotius, who was able to make good Latin verses at nine, was ripe for the university at twelve, and at fifteen edited the encyclopedic work of Marinus Capella. At Leyden he was much noticed by J. J. Scaliger, whose habit it was to engage his young friends in the editing of some classical text, less for the sake of the book so produced than as a valuable education for themselves. At fifteen Grotius accompanied Count Justin of Nassau, and the grand pensionary Oldenbarnevelt on their special embassy to the court of France. After a year profitably spent in that country in acquiring the language and making acquaintance with the leading

men, Grotius returned home. He took the degree of doctor of law at Leyden, and entered on practice as an advocate.

Notwithstanding his successes in his profession, which seemed to open the most brilliant career to his ambition, he was in secret hankering after the pleasures of literature. In 1600 he edited the remains of Aianus, with the versions of Cicero, Germanicus, and Avianus. Of the *Germanicus* Scaliger says—"A better taste than that which Grotius has given, it is impossible to give," but it is probable that Scaliger had himself been the reviser. Grotius vied with the Latinists of his day in the composition of Latin verses. Some lines on the siege of Ostend were greatly admired, and spread his fame beyond the circle of the learned. He wrote three dramas in Latin.—*Christus Patiens*, *Sophomphaneas*, on the story of Joseph and his brethren, and *Adamus Exul*, a production which is still remembered as having given hints to Milton. The *Sophomphaneas* was translated into Dutch by Vondel, and into English by Francis Goldsmith (1663), the *Christus Patiens* into English by George Sandys (1640).

In 1603 the United Provinces, desiring to transmit to posterity some account of their struggle with Spain, determined to appoint a historiographer. Several candidates appeared, Dominicus Bandius of course among them. But the choice of the states fell upon Grotius, though only twenty years of age, and not having offered himself for the post.

There was some talk at this time in Paris of calling Grotius to be librarian of the royal library. But it was never meant seriously. It was a ruse of the Jesuit party, who wished to persuade the public that the opposition to the appointment of Isaac Casaubon did not proceed from theological motives, since they were ready to appoint a Protestant in the person of Grotius.

His next profecment was that of advocate general of the sea for the provinces of Holland and Zealand. This was followed by his marriage, in 1608, to Mary van Bengeberg, a lady of family in Zealand, a woman of great capacity and noble disposition, who proved every way worthy to be the wife of Grotius.

He had already passed from occupation with the classics to studies more immediately connected with his profession. In the winter of 1601 he composed a treatise entitled *De jure pædæ*. This treatise he did not publish, and the MS of it remained unknown to all the biographers of Grotius till 1868, when it was brought to light, and printed at the Hague under the auspices of Professor Finck. It discovers to us that the principles and the plan of the celebrated *De jure belli*, which was not composed till 1625, more than twenty years after, had already been conceived by a youth of twenty-one. It has always been a question among the biographers what it was that determined Grotius, when an exile in Paris in 1625, to that particular subject, and various explanations have been offered, among others we have been referred to a casual suggestion of Paresce in a letter of early date. The discovery of the MS of the *De jure pædæ* discloses to us the whole history of Grotius's ideas, and shows us that from youth upwards he had steadily read and meditated in one direction, that, namely, of which the famous *De jure belli* was the mature product. In the *De jure pædæ* of 1604 we have much more than the germ of the later treatise *De jure belli*. Its main principles, and the whole system of thought implied in the later work, are anticipated in the earlier work. The arrangement even is the same. The chief difference between the two treatises is one which twenty years' experience in affairs could not but bring,—the substitution of more cautious and guarded language, less dogmatic affirmation, more allowance for exceptions and deviations. The *Jus pædæ*

was an addition introduced first in the later work, an insertion which is the cause of not a little of the confused arrangement which has been found fault with in the *De jure belli*.

We learn further from the *De jure pædæ* that Grotius was originally determined to this subject, not by any speculative intellectual interest, but by a special occasion presented by his professional engagements. He was retained by the Dutch East India Company as their advocate. The company had been formed for the peaceful purposes of commerce, but had found itself compelled by the aggressions of the Portuguese to repel force by force. One of their captains, Heemskerk, had captured a rich Portuguese galleon in the Straits of Malacca. The right of a private company to make prizes was hotly contested in Holland, and denied by the strictest theologians, especially the Mennonites, who considered all war unlawful. Grotius undertook to prove that Heemskerk's prize had been lawfully captured. In doing this he was led to investigate the grounds of the lawfulness of war in general. Such was the casual origin of a book which long enjoyed such celebrity that it used to be said, with some exaggeration indeed, that it had founded a new science.

A short treatise which was printed in 1609, Grotius says without his permission, under the title of *Mare Liberum*, is nothing more than a chapter of the 12th—of the *De jure pædæ*. It was necessary to Grotius's defence of Heemskerk that he should show that the Portuguese pretence that Eastern waters were their private property was untenable. Grotius maintains that the ocean is free to all, and cannot be appropriated by any one nation. The occasional character of this piece explains the fact that at the time of its appearance it made no sensation. It was not till many years afterwards that the jealousies between England and Holland gave importance to the novel doctrine broached in the tract by Grotius, a doctrine which Selden set himself to refute in his *Mare clausum*, 1633.

Equally due to the circumstances of the time was his small contribution to constitutional history entitled *De antiquitate reipublice Batavæ* (1610). In this he vindicates, on grounds of right, prescriptive and natural, the revolt of the United Provinces against the sovereignty of Spain.

On the death of Elias Oldenbarnevelt, Grotius, though only thirty, succeeded him as pensionary of the city of Rotterdam. Foreseeing the troubles impending from the growing theological fermentation, he made the stipulation that he should be removable by the municipal authorities—a stipulation certain not to be respected should it ever be wanted for his protection.

In 1613 he formed one of a deputation to the court of England, for the purpose of adjusting those differences which were already beginning to arise between the two young maritime powers, and which gave rise afterwards to a naval struggle disastrous to Holland. He was received by James with every mark of distinction due to his young reputation. He also cultivated the acquaintance of the Anglican ecclesiastes Overall and Andrewes, and was much in the society of the celebrated scholar Isaac Casaubon, with whom he had been in correspondence by letter for many years. Though the mediating views in the great religious conflict between Catholic and Protestant, by which Grotius was afterwards known, had been arrived at by him by independent reflexion, yet it could not but be that he would be confirmed in them by finding in England a developed school of thought of the same character already in existence. How highly Casaubon esteemed Grotius appears from a letter of his to Daniel Heinsius, dated London, 13th April 1613. "I cannot say how happy I esteem myself in having seen so much of one so truly great

as Grotius. A wonderful man! This I knew him to be before I had seen him, but the rare excellence of that divine genius no one can sufficiently feel who does not see his face, and hear him speak. Piety is stamped on his features, his conversation savours of true piety and profound learning. It is not only upon me that he has made this impression, all the pious and learned to whom he has been here introduced have felt the same towards him, the king especially so!"

After Grotius's return from England the exasperation of theological parties in Holland gradually rose to such a pitch that it became clear that an appeal to force would sooner or later be made. This Grotius must have foreseen, but he could hardly have anticipated that he himself would be one of the first and principal victims. Grotius was not sufficient of a philosopher to rise above the level of a mere theological wrangle. But from a natural moderation of temper he sought to find some mean town in which the two hostile parties of Remonstrants and Antiremonstrants, or as they were subsequently called Arminians and Gomaiists (see REMONSTRANTS), might agree. A form of edict drawn by Grotius was published by the states, recommending mutual toleration, and forbidding ministers in the pulpit from handling the disputed dogmas. To the orthodox Calvinists the word toleration was insupportable. They had the populace on their side. This fact determined the stadtholder, Maurice of Nassau, to support the orthodox party—a party to which he inclined the more readily that Oldenbarnevelt, the grand pensionary, the man whose uprightness and abilities he most admired, sided with the Remonstrants.

In 1618 Prince Maurice set out on a sort of pacific campaign, disbanding the civic guards in the various cities of Guelders, Holland, and Zealand, and occupying the places with troops on whom he could rely. The states of Holland sent a commission, of which Grotius was chairman, to Utrecht, with the view of strengthening the hands of their friends, the Remonstrant party, in that city. Feeble plans were formed, but not carried into effect, for shutting the gates upon the stadtholder, who entered the city with troops on the night of 20th July 1618. There were conferences in which Grotius met Prince Maurice face to face, and taught him that Oldenbarnevelt was not the only man of capacity in the ranks of the Remonstrants whom he had to fear. On the early morning of 31st July the prince's *coup d'état* against the liberties of Utrecht and of Holland was carried out, the civic guard was disarmed,—Grotius and his colleagues saving themselves by a precipitate flight. But it was only a reprieve. The grand pensionary, Oldenbarnevelt, the leader of the Remonstrant party, Grotius, and Hoogheboez were arrested by order of the stadtholder, brought to trial, and condemned,—Oldenbarnevelt to death, and Grotius to imprisonment for life and confiscation of his property. In June 1617 he was imprisoned in the fortress of Lovestein near Gozium. His confinement was rigorous, but after a time his wife obtained permission to share his captivity, on the condition that if she came out, she should not be suffered to return.

Grotius had now before him, at thirty-six, no prospect but that of a lifelong captivity. He did not abandon himself to despair, but sought refuge in returning to the classical pursuits of his youth. Several of his translations (into Latin) from the Greek tragedians and other writers, made at this time, have been printed. They are without any philological value, and only prove his taste and facility in the classical languages. "The Muses," he writes to Voss, "were now his consolation, and appeared more amiable than ever."

The address and ingenuity of Madame Grotius at length devised a mode of escape. It had grown into a custom to send, at stated intervals, the books which he had done with,

in a chest, along with his linen to be washed at Gozium. For many months the wardens of the fortress were very exact in searching the chest. But never finding anything but books and linen they grew careless, and began to let the chest pass without opening it. Madame Grotius, perceiving this, prevailed on her husband to allow himself to be shut up in it at the usual time. The two soldiers who carried the chest out complained that it was so heavy "there must be an Arminian in it." "There are indeed," said Madame Grotius, "Arminian books in it." The chest was carried by canal to Gozium. When it came there they wanted to put it on a sledge, but the maid telling the women there that she perceived some little things in it, it was put on a horse, and so carried to the house of a friend, where it was opened, and Grotius released. He was then dressed up like a mason with hod and trowel, and so conveyed in disguise over the frontier. His first place of refuge was Antwerp, from which he proceeded to Paris, where he arrived in April 1621. In October he was joined by his wife. There he was presented to the king, Louis XIII., and a pension of 3000 livres conferred upon him. French pensions were easily granted, all the more so as they were never paid. Grotius was now reduced to great straits. He had not the means of procuring the bare necessities of life. His family was a growing one, and it was with difficulty that he procured them clothes. His relations in Holland sent him occasionally small remittances in money, clothes, or Dutch butter. He looked about for any opening through which he might earn a living. There was talk of something in Denmark, or he would settle in Spain, and practise in the court there. Some little relief he got through the intervention of D'Aligre, the new chancellor, who procured a royal mandate which enabled Grotius to draw, not all, but a large part of his pension. In 1623 the president Henri de Mesme lent him his chateau of Balagni near Sens (Dep Oise), and there Grotius passed the spring and summer of that year. De Thou gave him facilities to borrow books from the superb library formed by his father.

Under these circumstances the *De jure belli et pacis* was composed. The biographers are naturally astonished by the fact that a work of such immense reading, consisting in great part of quotation, could have been written in little more than a year. The achievement would have been, not wonderful, but impossible, but for the fact above mentioned that Grotius had with him the first draft of the work made in 1604. He had also got his brother William, when he was reading his classics, to mark down all the passages which touched upon law, public or private. In March 1625 the printing of the *De jure belli*, which had taken four months, was completed, and the edition despatched to the fair at Frankfurt. His own honorarium as author consisted of 200 copies, of which, however, he had to give away many to friends, to the king, the principal courts, the papal nuncio, &c. What remained he sold for his own profit, at the price of a crown each, but the sale did not recoup him his outlay. But though his book brought him no profit it brought him reputation, so widely spread, and of such long endurance, as no other legal treatise has ever enjoyed.

Grotius naturally hoped that his fame would soften the hostility of his foes, and that his country would recall him to her service. In this he was disappointed. Theological rancour prevailed over all other sentiments. After some fruitless attempts to re-establish himself in Holland, Grotius was fain to accept an office under the crown of Sweden, in the capacity of ambassador to the court of France. He was not very successful in negotiating the treaty on behalf of the Protestant interest in Germany, Richelieu having a special dislike to him. He never enjoyed the confidence

of the court to which he was accredited, and flattered away his influence in disputes about precedence, which seem little worthy of his reputation.

In 1615 he demanded and obtained his recall. He was received at Stockholm with all the honours due to him. But neither the climate nor the tone of the court suited him, and he demanded permission to leave. He was driven by a storm on the coast near Dantzic. He got as far as Stockholm, where he found himself very ill. Stockman, a Scotch physician who was sent for, thought it was only weakness, and that rest would restore the patient. But Grotius sank rapidly, and died on 29th August 1645.

Grotius was a man of varied interests and accomplishments, combining a wide circle of general knowledge with a profound study of one branch of law. History, theology, jurisprudence, politics, classics, poetry—all these fields he cultivated, and has left numerous works in each kind.

His commentaries on the Scriptures were the first application on an extensive scale of the principle affirmed by Scaliger, that, namely, of interpretation by the rules of grammar, with its dogmatic assumptions. Grotius's philological skill, however, was not sufficient to enable him to work up to this ideal.

As in many other points Grotius inevitably recalls to us Erasmus, so he does in his attitude towards the great schism. Grotius was indeed a man of profound religious sentiment, which Erasmus was not, but he had an indifference to dogma equal to that of Erasmus, although his disregard sprang from another source. Erasmus felt the contempt of a man of letters for the barbarous dissension of the monkish wrangle. Grotius was animated by an ardent desire for peace and concord. He thought that a basis for reconciliation of Protestant and Catholic might be found in a common study, combined with reticence upon discrepancies of doctrinal statement. His *De veritate religionis Christiane* (1627), a presentation of the evidences, is so written as to form a code of common Christianity, irrespective of sect. The little treatise diffused itself rapidly over Christendom, gaining rather than losing popularity in the 18th century. It became the classical manual of apologetics in Protestant colleges, and was translated for missionary purposes into Arabic (by Pococke, 1660), Persian, Chinese, &c. His *Via ad evanum ad pacem ecclesiasticam* (1642) was a detailed proposal of a scheme of accommodation. Of course, like all men of moderate and mediating views, he was charged by both sides with vacillation. An Amsterdam minister, James Leusden, published his *Grotius paganus* (1642), and it was continually being announced from Paris that Grotius had "gone over." Hallam, who has collected all the passages from Grotius's letters in which the prejudices and narrow tenets of the Reformed clergy are condemned, thought he had a "bias towards popery" (*Lit. of Europe*, ii. 312). The true interpretation of Grotius's mind appears to be an indifference to dogmatic propositions, produced by a profound sentiment of piety. He rose above the sectarian bigotry of the vulgar theologian, but did not ascend into that philosophical region in which dogma is transcended and dissolved. He approached parties as a statesman approaches them, as facts which have to be dealt with, and governed, not suppressed in the interests of some one of their number.

His editions and translations of the classics were other juvenile exercises prescribed by Scaliger, or "Latin poetry," the amusement of vacant hours. Grotius read the classics as a humanist, for the sake of their contents, not as a professional scholar.

His *Annals of the Low Countries* was begun as an official duty while he held the appointment of historiographer, and was being continued and retouched by him to the last. It was not published till 1657, by his sons Peter and Cornelius.

But the high reputation which Grotius attained in his lifetime, though it rests in part, like that of Erasmus, on the diversity of his accomplishments and the comprehensiveness of his literary work, had also a scientific basis in a professional specialty. Grotius was a great jurist, and his *De jure belli et pacis* (Paris, 1625), though not by any means the first attempt in modern times to ascertain the principles of jurisprudence, went far more fundamentally into the discussion than any one had done before him. The title of the work was so far misleading that the *ius belli* was a very small part of his comprehensive scheme. In his treatment of the natural law question he borrows the work of Albericus Gentili (1588), and Ayala (1597) before him, and has acknowledged his obligations to them. But it is in the larger questions to which he opened the way that the merit of Grotius consists. It was the first attempt to obtain a principle of right, and a basis for society and government, outside the church or the Bible. The distinction between religion on the one hand and law and morality on the other is not indeed clearly conceived by Grotius, but he wrestles with it in such a way as to make it easy for those who followed him to seize it. The law of nature is unalterable, God Himself cannot alter it any more than He can alter a mathematical axiom. This law is its source in the nature of man as a social being, it would be valid even were there no God, or if God did not interfere in the government of the world. These positions, though Grotius's religious temper did not allow him to rely unreservedly upon them, yet, even in the partial application they find in his book, entitle him to the honour of being held the founder of the modern science of the law of nature and nations. The *De jure* exerted little influence on the practice of belligerents, yet its publication was an epoch in the science. "The elegance of his diction," says Bluntschli, "the pearls from classical antiquity with which he adorned his pages, the temper of humanity which pervaded his arguments, his effort to mitigate the horrors of the Thirty Years' War in the midst of which he wrote, and the warmth of his general sympathy for a moral as opposed to a material order, enlisted men's hearts on the side of his reasoning, while the deficiencies of his doctrine were not as yet detected." These defects are probably now, at 250 years' distance of time, more palpable than the merits of the work. But only in the heat and impetuosity of irresponsible periodical criticism could it be said, as De Quincey has said, that the book is equally divided between "empty truths and time-serving Dutch falsehoods." For a saner judgment and a brief abstract of the contents of the *De jure*, the reader is referred to Bluntschli, *Geschichte des allgemeinen Staatsrechts* (Munich, 1861). A fuller analysis, and some notice of the predecessors of Grotius, will be found in Helly, *Histoire du droit de la guerre et de la paix* (Paris, 1875). The writer, however, with the usual misapprehension of Frenchmen with everything which goes on outside France, has never heard of the *De jure pacis*, published in 1669. Hallam, *Lit. of Europe*, ii. p. 513, has an abstract done with his usual conventional panegyric David Stewart (*Collected Works*, i. 370) has dwelt upon the confusion and defects of Grotius's theory. Mackintosh (*Miscell. Works*, p. 166) has defended Grotius, affirming that his work "is perhaps the most complete that this world has yet owed, at so early a stage in the progress of any science, to the genius and learning of one man."

The chief writings of Grotius have been named in the course of our article. For a complete bibliography of his works, published in the edition of his works by his son, *Opera et scripta Grotiana*, Paris, 1727, which also contains a full bibliography. Of this Latin list De Bary published a translation in French, 2 vols. 8vo, Paris, 1762. Other lists are—Van Thun, *Historie van het Leven en de Geschiedenis*, 2 vols. 8vo, Amsterdam, 1727; Von Laun, *Leben Grotius nach seinen Schriften*, und

Schizium doryfolium, Sw., Berlin, 1806, *Life of Hugo Grotius*, by Charles Buckle of Lincoln Inn, 8vo., London, 1824. The vol. of the Abbe. Hely already mentioned contains a life of Grotius Grotius's theological works were collected in 8 vols fol. at Amstelr. 1644-46 (quoted London, 1800, Amsterdam, 1679, and again Amsterdam, 1698). His letters were printed first in a selection, *Epistolæ ad Gallos*, 12mo., Leyden, 1618, abounding, though an *hlevit*, in errors of press. They were collected in *H. Grotius Epistolæ quædam selectæ*, 4to., fol., Amsterdam, 1687. A *lex* may be found, either in other collections of *Statuta* Supplements to the huge collection of 1687 were published at Harlem, 1806, Leyden, 1809, and Harlem, 1829. The *De jure belli* was translated into English by Whewell, 8 vol. 8vo., Camb., 1868, into French by Bulygaev, 3 vol. 8to., Amat., 1721, into German in Kirchmann's *Philosophische Bibliothek*, 8 vols 12mo., Leipzig, 1799. (M P)

GROTON, a post town of New London county, Connecticut, U S, is situated on the rivers Myxide and Pequonock, opposite New London, and on the east side of the river Thames at its junction with Long Island Sound. There are granite quarries in the neighbourhood, and the town possesses manufactures of cotton goods, batanna ware, cutlery, and sashes and blinds, and brass and iron foundries. There is also a considerable coasting trade, and shipping and fishing are carried on to a small extent. On the heights behind the town stands Fort Griswold, which surrendered to the British troops, September 6, 1781. The majority of its defenders, including the commander Colonel Ledyard, were put to death after they had surrendered, and a granite monument was erected in the town to their memory in 1830. The population in 1870 was 5124.

GROTTAGLIE, a small city of Italy, in the province of Lecce and circondario of Taranto, about 14 miles N E of Taranto. It probably occupies the site of Rudia, the birth place of the Latin poet Ennius, afterwards known as Castell Rodella. The name Grottaglie is due to the number of caves in the vicinity. In modern times the place is worthy of note mainly because it has given birth to several men of considerable national eminence, as is set forth in detail in Pignatelli's history of the town. An excellent road lay for the manufacture of earthenware is found at Grottaglie. The inhabitants numbered 8747 in 1871.

GROUND NUT (synonyms, Earth Nut, Pistachio de Totto, Monkey Nut, Fox Nut, Manilla Nut), a nut or pod the produce of the *Arachis hypogæa*, L. (Nat. Ord. Leguminosæ). The plant is an annual of diffuse habit, with hairy stem, with two-paired, abruptly pinnate leaflets. The flowers above ground are sterile, and the pods or legumes are stalked, oblong, cylindrical, about 1 inch in length, the thin reticulated shell containing one or two irregularly ovoid seeds. After the flower withers, the stalk of the ovary has the peculiarity of elongating and bending down, forcing the young pod under ground, and thus the seeds become matured at some distance below the surface. Hence the specific and vernacular names of the plant. Two varieties are recognized in Malacca and Java, a white and a brown, and the seeds are known as *mynah katung* (oil bean). Of the history of this plant much has been written. Monardes in 1596 writes of having seen it largely used about the river Maafion in Brazil, and Maiegraf in 1648 gave a description and figure of it. To M. Joubert, however, a colonist at Godee near Cape Verd, seems to belong the honour of first recommending it as of commercial value. As to its native country the opinions of botanists are divided between Africa and America. It is extensively cultivated in all tropical and subtropical countries, especially in America, Africa, India, the Malayan Archipelago, and China. The plant affects a light sandy soil, and is very prolific, yielding in some instances 30 to 38 bushels of nuts per acre. The pods when ripe are dug up and dried. The seeds when fresh are largely eaten in tropical countries, and in taste are almost equal to almonds, when roasted they are used as a substitute for chocolate. Even in England large

quantities of these "monkey nuts" are consumed by the poorer children. By expression the seeds yield a large quantity of oil, which is used by natives for lamps, as a fish or curry oil, and for medicinal purposes. The leaves form an excellent food for cattle, being very like clover.

Large quantities of seeds are imported to Europe, chiefly to Marseilles, London, Hamburg, and Berlin, for the oils of them contained oil. The seeds yield from 42 to 50 per cent of oil by cold expression, but a larger quantity is obtained by heat, although of an inferior quality. The seeds being soft facilitate mechanical expression, and when sulphuric acid or other solvent is used, a very pure oil is obtained.

The expressed oil is limpid, of a light yellowish or straw colour, having a faint smell and bland taste, it forms an excellent substitute for olive oil, although in a slight degree more prone to rancidity than the latter. Its specific gravity is 0.918 to 0.918, it becomes turbid at 3° C., concretes at +3° to -4° C., and hardens at +7° C. It is a non-drying oil. Ground nut oil consists of (1) oleic acid ($C_{18}H_{34}O_2$), (2) hypogæic acid ($C_{18}H_{32}O_2$), by some supposed to be identical with a fatty acid found in whale oil, (3) palmitic acid ($C_{16}H_{32}O_2$), and (4) arachic acid ($C_{26}H_{52}O_2$). The oil is official in the Indian pharmacopœia, replacing olive oil, and it is also used in the adulteration of gummy oil. In 1874 about 145 million lb of ground nuts, valued at £1,040,000, were exported from the west coast of Africa, chiefly to Marseilles, London, Hamburg, and Berlin.

GROUNDSEL (*Gaumen*, *Krauswurtz*, French, *Senecio*), *Senecio vulgaris*, Linn., is an annual, glabrous or more or less woolly plant of the natural order Compositæ, series *Tubulifloræ* and tribe *Senecioideæ*, having a branched succulent stem 6 to 15 inches in height, pinnatifid and irregularly and coarsely toothed leaves, flowers in separate corymbs, with involucre of about 20 equal and several external and smaller bracts, and florets yellow and tubular, rarely ligulate in the marginal row, and ribbed and silky fruit. The plant is indigenous to Europe, whence it has been introduced into all temperate climates. It is a troublesome weed, flowering throughout the year, and propagating itself rapidly by means of its light feathery fruits, it has its use, however, as a food for sage-birds. *Senecio sylvestris* and *S. jacobæ* are known respectively as mountain groundsel and stinking groundsel. Many species of the genus are handsome florists' plants. The groundsel tree, *Baccharis halimifolia*, Linn., a native of the North American sea-coast from Massachusetts southward, is a Composite shrub, attaining 6 to 12 feet in height, and having angular branches, obovate or oblong-lanceolate, somewhat scurfy leaves, and flowers larger than but similar to those of common groundsel. The long white pappus of the female plant renders it a conspicuous object in autumn. The groundsel tree has been cultivated in British gardens since 1683.

See London, *Arborescens*, vol. ii., 1888, *Synonymy*, *English Botany*, vol. v., 3d ed., 1866.

GROUSE, a word of uncertain origin,¹ now used generally by ornithologists to include all the "rough-footed" Gallinaceous birds, but in common speech applied almost

¹ It seems first to occur (*Inde* O. Sinsbury Breerton, *Archæologia*, in p. 157) in an ordinance for the regulation of the royal household dated "apud Eltham, mens Jan II^{us} Hen VIII," i. e., 1531, and considering the locality must refer to Black grouse. It is found in an Act of Parliament 1 Jac I cap 27, § 2, i. e., 1603, and, as is printed in the *Statutes at Large*, stands as now commonly spelt, but by many writers on printers the final *s* is now omitted. In 1611 Colgrave had, *Poule grousche*. A Moore has, the home of the *Grouse* in ed 1873 "Grouse" or "Moongrouse" (*Antiquities of the Welsh and English Tongues*, vol. v. 1866). The most likely derivation seems to be from the old French word *grouse*, *grouse*, or *Grouse* (meaning speckled, and cognate with *grasse*, grainy or grey), which was applied to some kind of Partridge, or according to *Etymologia*, p. 211) to a Quail, "porce que ele fu premiers trovée en Grece."

exclusively, when used alone, to the *Tetrao scoticus* of Linnaeus, the *Lagopus scoticus* of modern systematists—more particularly called in English the Red Grouse, but not a century ago almost invariably spoken of as the Moor-fowl or Moorgame. The effect which this species is supposed to have on the British legislature, and therefore on history, is well known, for it is the common belief that parliament in these days always rises when the season for Grouse-shooting begins; but even of old time it seems to have excited on one occasion a curious kind of influence, for we may read in the *Orkneyingay Saga* (ed. Jones, p. 366; ed. Anderson, p. 168) that events of some importance in the annals of North Britain followed from its pursuit in Caithness in the year 1167. The Red Grouse is found on moors from Monmouthshire and Derbyshire northward to the Orkneys, as well as in most of the Hebrides. It likewise inhabits similar situations throughout Wales and Ireland, but it does not naturally occur beyond the limits of the British Islands,¹ and is the only species among birds peculiar to them. The word "species" may in this case be used advisedly (since the Red Grouse invariably "breeds true," it admits of an easy diagnosis, and it has a definite geographical range); but scarcely any zoologist who looks further into the matter can doubt of its common origin

Red Grouse.

with the Willow-Grouse, *Lagopus albus* (L. subalpinus or L. sublectus of some authors), that inhabits a subarctic zone from Norway across the whole continent of Europe and Asia, as well as North America from the Aleutian Islands to Newfoundland. The Red Grouse indeed is rarely or never found away from the heather on which chiefly it subsists, and with which in most men's minds it is associated; while the Willow-Grouse in many parts of the Old World seems to prefer the shrubby growth of berry-bearing plants (*Vaccinium* and others) that, often thickly interspersed with willows and birches, clothes the higher levels or the lower mountain-slopes, and it contrives to flourish in the New World where heather scarcely exists, and a "heath" in its strict sense is unknown. It is true likewise that the Willow-Grouse always becomes white in winter, which the Red Grouse never does; but then we find that in summer there is a considerable resemblance between the two species, the cock Willow-Grouse having his head, neck, and breast of nearly the same rich chestnut-brown as his British

representative, and, though his back be lighter in colour, as is also the whole plumage of his mate, than is found in the Red Grouse, in other respects than those named above the two species are precisely alike. No distinction can be discovered in their voice, their eggs, their build, nor in their anatomical details, so far as these have been investigated and compared.² In connexion too with this matter it should not be overlooked that the Red Grouse, restricted as is its range, varies in colour not inconsiderably according to locality, so that game-dealers of experience are able to pronounce at sight the native district of almost any bird that comes to their hands.

Other peculiarities of the Red Grouse—the excellence of its flesh, and its economic importance, which is perhaps greater than that of any other wild bird in the world—hardly need notice here, and there is not space to dwell upon that dire and mysterious malady to which it is from time to time subject, primarily induced, in the opinion of many, by the overstocking of its haunts and the propagation of diseased offspring by depauperized parents.³

Though the Red Grouse does not, after the manner of other members of the genus *Lagopus*, become white in winter, Scotland possesses a species of the genus which does. This is the Ptarmigan, *L. montanus* L. *alpinus*, which differs far more in structure, and habits, from the Red Grouse than that does from the Willow-Grouse, and in Scotland is far less abundant, haunting only the highest and most barren mountains. It is said to have formerly inhabited both Wales and England, but there is no evidence of its appearance in Ireland. On the continent of Europe it is found most numerously in Norway, but at an elevation far above the growth of trees, and it occurs on the Pyrenees, and on the Alps. It also inhabits northern Russia, but its eastern limit is unknown. In North America, Greenland, and Iceland it is represented by a very nearly allied form—so much so indeed that it is only at certain seasons that

¹ A very interesting subject for discussion would be whether *Lagopus scoticus* or *L. albus* has varied most from the common stock of both. We can here but briefly indicate the more salient points that might arise. Looking to the fact that the former is the only species of the genus which does not assume white clothing in winter, an evolutionist might at first deem the variation greatest in its case; but then it must be borne in mind that the species of *Lagopus* which turn white differ in that respect from all other groups of the family *Troglodytidae*. Furthermore it must be remembered that every species of *Lagopus* (even *L. leucurus*, the whitest of all) has its first set of summer coloured feathers. These are dropped when the bird is about half-grown, and in all the species but *L. scoticus* white plumage is then produced. If therefore, as is generally held, the successive plumages are assumed by season in the course of its progress to maturity indicate the phases through which the species has passed, there may have been a time when all the species of *Lagopus* were a brown livery even when adult, and the white dress donned in winter has been imposed upon the species by causes that can be easily suggested, for it has been freely admitted by naturalists of all schools that the white plumage of the birds of this group protects them from danger during the snows of a protracted winter. On the other hand it is not at all inconceivable that the Red Grouse, instead of perpetuating directly the more ancient properties of an original *Lagopus* that underwent no great seasonal change of plumage, may derive its ancestry from the widely-ranging Willow-Grouse, which in an epoch comparatively recent (in the geological sense) may have stocked Britain, and left descendants that, under conditions in which the assumption of a white garb would be almost fatal to the preservation of the species, have reverted (though doubtless with some modification) to a comparative immutability essentially the same as that of the primal *Lagopus*.

² On the Grouse-disease the papers of Prof. Young in *Proc. Nat. Hist. Soc. Glasgow*, t. p. 225, and Dr Farguharson, *Edinb. Med. Journal*, No. 248, p. 268, may be advantageously consulted.

³ James I. (as quoted by Mr Gray, B. IV. *Scotland*, p. 280) writing from Whitehall in 1617 spelt the word "Ptarmigan," and in this form it appears in one of the Scots Acts in 1631. Taylor the "water poet," who (in 1680) seems to have been the first Englishman to use the word, has "Ptarmigan." How the unnecessary initial letter crept into the name is more than the writer knows. The word is admittedly from the Gaelic *Tormachan*, meaning, according to some, "a dweller upon heights," but thought by Dr T. M. Lachlan to refer possibly to the noise made by the bird's wings in taking flight.

¹ It has been successfully, though with much trouble, introduced by Mr Oscar Dickson on a tract of land near Gothenburg in Sweden (*Svenska Jägareförbundet's Års Tidsskrift*, 1868, p. 64 of *aktien*), and seems likely to maintain itself there, so long at least as the care hitherto bestowed upon it is continued.

the slight difference between them can be detected. This form is the *L. septentrionalis* of authors, and it would appear to be found also in Siberia (*Ibid.*, 1879, p. 148). Spitzbergen is inhabited by a large form which has received recognition as *L. hutchinsoni*, and the northern end of the chain of the Rocky Mountains is tenanted by a very distinct species,

PTARMIGAN

the smallest and perhaps the most beautiful of the genus *L. leucurus*, which has all the feathers of the tail white. The very curious and still hardly understood question of the moulting of the Ptarmigan could not possibly be discussed within these limits—reference has already been made to it in another article (*IBID.*, vol. III, p. 776).

The bird, however, to which the name of Grouse in all strictness belongs¹ is probably the *Tetrao tetrix* of Linnæus

BLACKCOCK

—the Blackcock and Greyhen, as the sexes are with us respectively called. It is distributed over most of the heath-country of England, except in East Anglia, where attempts to introduce it have been only partially successful. It also occurs in North Wales, and very generally throughout Scotland, though not in Orkney, Shetland, or the Outer

Hebrides, nor in Ireland. On the continent of Europe it has a very wide range, and it extends into Siberia. In Gen. &c. its place is taken by a distinct species, on which a Polish naturalist (*Proc. Zool. Society*, 1874, p. 367) has unhappily conferred the name of *T. nicholsoni*. Both these birds have much in common with their larger congeners the Capercaillies (see vol. V, p. 53) and its eastern representative.

We must then notice the species of the genus *Bonasa*, of which the European *B. sylvestris* is the type. This does not inhabit the British Islands, unfortunately so, for it is perhaps the most delicate game-bird that comes to table. It is the *Gelinotte* of the French, the *Muselhuhn* of Germans, and *Hjerpe* of Scandinavians. Like its transatlantic congener *B. umbellus*, the Ruffed Grouse or Buch-Patridge (of which there are two other local forms, *B. umbelloides* and *B. erbmii*), it is purely a forest-bird. The same may be said of the species of *Canace*, of which two forms are found in America, *C. canadensis*, the Spruce-Patridge, and *C. franklini*, and also of the Siberian *C. talpensis*. Nearly allied to these birds is the group known as *Dendragapus*, containing three large and fine forms *D. obscurus*, *D. fuliginosus*, and *D. richardsoni*—all peculiar to North America. Then we have *Centrocercus urophasianus*, the Sage cock of the plains of Columbia and California, and *Petroperca*, the Sharp-tailed Grouse, with its two forms *P. phasianellus* and *P. columbianus*, which finally *Oryzopsis*, the Prairie hen, also with two local forms, *O. capado* and *O. pallidirostris*, is a bird that in the United States of America possesses considerable economic value, as witness the enormous number that are not only consumed there, but exported to Europe. It will be seen that the great majority of Grouse belong to the northern part of the New World, and it is much to be regretted that space here fails to do justice to these beautiful and important birds, by enlarging on their interesting distinctions. They are nearly all figured in Elliot's *Monograph of the Tetraoninae*, and an excellent account of the American species is given in Band, Brewer, and Ridgway's *North American Birds* (in pp. 414-465). (X.)

GROVE The almost universal occurrence, at one stage or another in the religious and social development of the races of mankind, of the practice of worshipping by preference under or among trees to which a peculiarly sacred and inviolable character is attached, is a fact too well known to require particular illustration here. Its explanation is to be sought partly in obvious considerations of physical convenience, but even more in certain psychical phenomena which may still be made matters of direct observation and experience ("Lucas, et in us silencia ipsa eloquuntur," Pliny, *H. N.*, xii. 1. "Societatem lucus ad administrandum fidem tibi munus facit," Sen., *Æl.* x.) It does not appear to have any necessary connexion with tree-worship, another very widely diffused practice, on which, and on its possible connexion with ancestor-worship, some suggestive remarks will be found in Spencer's *Principles of Sociology*. It has sometimes been alleged as a characteristic difference between the Semitic and the Aryan races that the former show a tendency to select single trees for sanctuaries, while the latter are generally found worshipping in groves, and this generalization, though liable to many exceptions, is really borne out at least by the familiar instances to be met with in Scripture. The word "grove" so often met with in the authorized version of the Bible, is nowhere there correctly employed. In Gen. xxi. 33 and 1 Sam. xxi. 9 (margin) it is used as a rendering of the Hebrew word גֵּזֶר which "tamausk" is the proper translation. In every other instance in which it occurs (*Ex.* xxxiv. 13; *Deut.* xii. 3, xvi. 21, *Judg.* vi. 7, vi. 25, 28, *Isa.* xvi. 8, *Mic.* v. 14, and often in Kings and Chronicles), where the LXX. translate δέντρον, and the Vulgate lucus, the

¹ See footnote, p. 221

original is invariably Asherah (אשרה), meaning a tree or post (see BALT, vol. i, p. 175). The "plant" of Moriah, or Mamre also, in Gen. xii. 6 and xiii. 18, represents ysh, which all modern interpreters render "tree elench."

GRUBER, JOSEPH GOTTFRIED (1774-1851), a learned German author, was born at Naumburg on the Saale, 29th November 1774. He received his education at the town school of Naumburg and the university of Leipzig, after which he resided successively at Göttingen, Leipzig, Jena, and Weimar, occupying himself partly in teaching and partly in various literary enterprises, and enjoying in Weimar the friendship of Herder, Wieland, and Goethe. In 1811 he was appointed professor at the university of Wittenberg, and after the division of Saxony he was sent by the senate to Berlin in connection with the negotiations for the union of the university of Wittenberg to that of Halle. After the union was effected he became in 1815 professor of philosophy at Halle. On the death of Hufeland he was associated with Erich in the editorship of the great work *Allgemeine Encyclopädie der Wissenschaften und Künste*, and after the death of Erich he continued the first section from vol. xviii to vol. lvi. He also succeeded Erich in the editorship of the *Allgemeine Literaturzeitung*. He died 7th August 1851.

Gruber was the author of a huge number of works, the principal of which are *Überlieferungen der Vorwelt*, in conjunction with Deane, Leipzig, 1806, *Grundriss der Menschlichen Geschichte*, 2 vols., Leipzig, 1806, *Wörterbuch der Altclassischen Mythologie*, 2 vols., Weimar, 1810-15, *Waldes Leben*, 2 parts, Weimar, 1815-16, and *Kleinode Lebus*, Weimar, 1816. A complete bibliography of Gruber was prefixed to Gubik's edition of Wieland's *Sämmtliche Werke*, Leipzig, 1818-28.

GRÜN, ANASTASIVUS (1806-1876), pseudonym for Anton Alexander, count of Auenberg, who was born April 11, 1806, at Laibach, the capital of the Austrian duchy of Carinthia. He received his university education first at Glatz and then at Vienna, where he studied jurisprudence. In 1832 the title of "Imperial Chamberlain" was conferred upon him, and in 1839 he married the daughter of Count Attems. He accepted no official post, and devoted himself chiefly to literary pursuits. When the "March Revolution" broke out in 1848 at Vienna, the count entered the political arena, and represented the district of Laibach at the National Assembly at Frankfurt-on-the-Main. After a few months, however, he resigned his seat, and again retired into private life. In 1860, when a fresh impulse was given to political life in Austria, he resumed his activity as a politician, and greatly distinguished himself in the Austrian House of Lords as one of the most intrepid and influential supporters of the cause of liberalism, both in political and religious matters, until his death in 1876. Count Auenberg acquired great fame as a poet, as which he is known under the pseudonym of *Anastasis Grün*. His first publication, *Blätter der Liebe*, "Leaves of Love" (1830), showed little originality, but his second production, *Der letzte Ritter*, "The last Knight" (1830), brought to light his eminence as a poet. It celebrates the deeds and adventures of the emperor Maximilian I. (1493-1519), and contains exquisite poetical descriptions tinged with playful humour. His next poetical productions, *Sprachspiele eines Wiener Poeten*, "Walks of a Vienna Poet" (1831), and *Schnee*, "Rains" (1836), quite electrified the whole of Germany by the boldness and originality of their conception and by their decided liberal tendency. His *Collected Poems* (1837) increased his reputation as a poet, but not so his epic, *Die Nibelungen von Pfalz* (1843) and *Der Pfaff vom Kahlenberg* (1850). He also produced masterly translations of the popular Slovenic songs eminent in Carinthia (1850), and of the English poems relating to "Robin Hood" (1860). Anastasis Grün may be called the originator of the modern school of political lyric poetry in Germany. His language

is sonorous and majestic, and his descriptions, though sometimes overclouded with imagery, bear the stamp of great poetical originality. He loved to employ the stately "Nibelungen measure," which imparted considerable vigour to some of his productions. Of his shorter poems *Der letzte Dichter*, "The last Poet," is deservedly the most popular.

GRÜN, HANS BALDUNG (c. 1470-1545), commonly called Grün, a painter of the age of Dürer, was born about 1470 at Gmund in Swabia, and spent the greater part of his life at Shwaburg and Freiburg in Brisgau. The earliest pictures assigned to him are altarpieces with the monogram H B interlined, and the date of 1496, in the monastery chapel of Lichtensthal near Baden. Another early work is a portrait of the emperor Maximilian, drawn in 1501 on a leaf of a sketch-book now in the print-room at Karlsruhe. The *Martyrdom of St. Sebastian* and the *Epiphany* (Berlin Museum), fruits of his labour in 1507, were painted for the market church of Halle in Saxony. In 1509 Grün purchased the freedom of the city of Shwaburg, and resided there till 1513, when he moved to Freiburg in Brisgau. There he began a series of large compositions, which he finished in 1516, and placed on the high altar of the Shwaburg cathedral. He purchased anew the freedom of Shwaburg in 1517, resided in that city as his domicile, and died a member of its cathedral council 1518.

Though nothing is known of Grün's youth and education, it may be inferred from his style that he was no stranger to the school of which Dürer was the chief. Gmund is but 50 miles distant on either side from Augsburg and Nuremberg. Grün's prints were often mistaken for those of Dürer, and Dürer himself was well acquainted with Grün's woodcuts and copper-plates, in which he traded during his trip to the Netherlands (1520). But Grün's prints, though Düreresque, are far below Dürer, and his paintings are below his prints. Without absolute correctness as a draughtsman, his conception of human form is often very unpleasant, whilst a questionable taste is shown in ornament equally profuse and "baroque." Nothing is more remarkable in his pictures than the puglike shape of the faces, unless we except the coarseness of the anatomies. No trace is apparent of any feeling for atmosphere or light and shade. Though Grün has been commonly eiled the *Correggio of the north*, his compositions are a curious medley of glaring and heterogeneous colours, in which pino black is contrasted with pale yellow, dirty grey, impure red, and glowing green. Flesh is a more glaze under which the features are indicated by lines. No wonder that English collectors should have neglected him. There is not one of his pictures in the whole of Great Britain, unless a work called "Youth and Old Age" in the Liverpool Institution, bought by Roscoe as a masterpiece of Antonello di Messina. Even Germans express but slight esteem for Grün, and if his works have any claims to attention at all, it is merely because of the wild and fantastic strength which some of them display. We may pass lightly over the *Epiphany* of 1507, the *Crucifixion* of 1512, or the *Stoning of Stephen* of 1523, in the Berlin Museum. There is some force in the *Dance of Death* of 1517, in the museum of Basel, or the *Madonna* of 1530, in the Lichtensthal Gallery at Vienna. Grün's best effort is the altarpiece of Freiburg, where the Coronation of the Virgin, and the Twelve Apostles, the Annunciation, Visitation, Nativity, and Flight into Egypt, and the Crucifixion, with portraits of donors, are executed with some of that fearful power which Manu Schöen bequeathed to the Swabian school. As a portrait painter he is well known. He drew the likeness of Maximilian V., as well as that of Maximilian, and his bust of Margrave Philip in the Munich Gallery tells us that he was connected with the reigning family of Baden.

early a. 1514. At a later period he had sittings from Margrave Christopher of Baden, Otilia his wife, and all their children, and the picture containing these portraits is still in the grand-ducal gallery at Karlsruhe. Lake Durea and Cianachi, Olten became a hearty supporter of the Reformation. He was present at the diet of Augsburg in 1518, and one of his woodcuts represents Luther under the protection of the Holy Ghost, which hovers over him in the shape of a dove.

GRUNBERG, or GRÜNBURG, a town of Prussian Silesia, chief town of a circle in the government district of Liegnitz, is beautifully situated on an affluent of the Oder, and on the railway from Breslau to Stettin by Kustrin, 36 miles N N W of Glogau. It has a real-school of the first order, a higher female school, and a trade school. The prosperity of the town depends chiefly on the vine culture in the neighbourhood, from which, besides the exportation of a large quantity of grapes, about 700,000 gallons of wine are manufactured annually. The wine is a kind of champagne, and is largely exported to Russia. There are also manufactures of machinery, cloth, preserved fruits, and lignite. The population of the town in 1876 was 12,200.

GRUNDTVIG, NIKOLAI FRANKRICH SAVANUS (1768–1872), the Danish poet, statesman, and divine, was born at Udby on the 8th of September 1768, in 1791 he was sent to live at the house of a priest in Jutland, and studied at the free school of Aarhus until he went up to the university of Copenhagen in 1800. At the close of his university life he made Iceland his special study, until in 1805 he took the position of tutor in a house on the island of Langeland. The next three years were spent in the study of Shakespeare, Schiller, and Fichte. His cousin, the philosopher Henrik Steffens, had returned to Copenhagen in 1802 full of the teaching of Schelling, and his lectures and the early poetry of Colanuschlager opened the eyes of Grundtvig to the new era in literature that was commencing. The latter began to essay writing himself, but his first work, *On the Songs in the Edda*, attracted no attention. Returning to Copenhagen in 1808, he achieved a greater success with his *Northern Mythology*, and in 1809 with his *Decline of the Heroic Life in the North*. The boldness of his theological views having provoked opposition, he retired to a country parsonage for a while, but soon returned to pursue a literary career with extraordinary eagerness. From 1811 to 1813 he published five or six works, of which the *Rime of Eorik* is the most remarkable. From 1818 to 1819 he was editor of a polemical journal entitled *Danmarkske*, and in 1818 to 1822 appeared his Danish paraphrases of Savoy Grammaticians and Snorre. During these years he was preaching to an enthusiastic congregation in Copenhagen, but he accepted in 1821 the country living of Præsto, only to return to the metropolis the year after. His theological career was, however, presently stopped, for, having in 1825 published a brochure, *The Church's Reply*, against the popular Dr. Clausen, he was publicly proscribed and fined. For seven years he was forbidden to preach, years which he spent in publishing a collection of his theological works, in paying two visits to England, and in studying Anglo-Saxon. In 1832 he obtained permission to preach again, and in 1839 he became priest of the workhouse church of Vaitou Hospital, a post he continued to hold until his death. In 1837 he published *Songs for the Danish Church*, a rich collection of spiritual poems, in 1838 he brought out a selection of early Scandinavian verse, in 1840 he edited the Anglo-Saxon poem of the *Phoenix*, with a Danish translation. He visited England a third time in 1843. From 1844 until after the first German war Grundtvig took a very prominent part in politics. In 1861 he received the titular rank of bishop, but without a see. He went on writing occasional poems

until 1866, and preached in the Vaitou every Sunday until a month before his death. He was married three times, his last time in his seventy-sixth year, and left children by each marriage. He died September 2, 1872. Grundtvig holds a unique position in the literature of his country, he has been styled the Danish Carlyle. He was above all things a man of action, not an artist, and the formless vehemence of his writings, which have had a great influence over his own countrymen, is hardly agreeable or intelligible to a foreigner. His spiritual poems are among the best that the North has produced, but they are apt to be too long. The writings of Grundtvig have not yet been collected in a permanent form, but the best of his poetical works were published in a selection by his eldest son, Evend Grundtvig, the eminent comparative mythologist, in 1869, with a critical memoir by the poet Høstnap, who belongs to the religious body denominated Grundtvigians.

GRUNEWALD, MATTHIAS. The accounts which are given of this painter, a native of Aschaffenburg, are curiously contradictory. Between 1518 and 1530, according to statements adopted by Waagen and Passavant, he was commissioned by Albert of Brandenburg, elector and archbishop of Mainz, to produce an altarpiece for the collegiate church of St Maurice and Mary Magdalen at Halle on the Saale, and he acquitted himself of this duty with such cleverness that the pietists in after years caused the picture to be rescued from the Reformers and brought back to Aschaffenburg. From one of the churches of that city it was taken to the Pinakothek of Munich in 1836. It represents St Maurice and Mary Magdalen between four saints, and displays a style so markedly characteristic, and so like that of Lucas Cranach, that Waagen was induced to call Grunewald Cranach's master. He also traced the same hand to a technical execution in the great altarpiece of Amunberg and Heilbronn, and in various panels exhibited in the museums of Mainz, Darmstadt, Aschaffenburg, Vienna, and Berlin. A fatal error of critics, declining to accept the statements of Waagen and Passavant, affirm that there is no documentary evidence to connect Grunewald with the pictures of Halle and Amunberg, and they quote Sandart and Reinhard Jobin of Strasburg to show that Grunewald is the painter of pictures of a different class. They prove that he finished before 1516 the large altarpiece of Isenheim, at present in the museum of Colmar, and stating from these premises they connect the artist with Altdorfer and Dürer to the exclusion of Cranach. That a native of the Palatinate should have been asked to execute pictures for a church in Saxony can scarcely be accounted strange, since we observe that Hans Baldung was entrusted with a commission of this kind. But that a painter of Aschaffenburg should display the style of Cranach is strange and indeed incredible, unless vouched for by first class evidence. In this case documents are altogether wanting, whilst on the other hand it is beyond the possibility of doubt, even according to Waagen, that the altarpiece of Isenheim is the creation of a man whose teaching was altogether different from that of the painter of the pictures of Halle and Amunberg. At this stage the controversy now stands, and it is needless to do more than observe that the altarpiece of Isenheim is a fine and powerful work, completed as local records show before 1516 by a Swabian, whose distinguishing mark is that he followed the traditions of Martin Schongauer, and came under the influence of Altdorfer and Dürer. As a work of art the altarpiece is important, being a polyptych of eleven panels, a carved central shrine covered with a double set of wings, and two side-pieces containing the Temptation of St Anthony, the hermit Anthony and Paul in converse, the Virgin adorned by Angels, the Resurrection, the Annunciation, the Crucifixion, St Sebastian, St Anthony, and the Marys

wailing over the dead body of Christ. The author of these compositions is also the painter of a series of monochromes described by Sandart in the *Dominican convent*, and now in part in the *Salhof* at Frankfurt, and a *Resurrection* in the museum of Basel, registered in Amerbach's inventory as the work of Gurnswald.

GRUTER, or GRUTERUS, JAN (1560-1627), a critic and scholar of Dutch parentage by his father's side and English by his mother's, was born at Antwerp, December 3, 1560. To avoid religious persecution his parents while he was still young came to England, and for some years he prosecuted his studies at Cambridge, after which he went to Leyden, where he graduated M.A. In 1586 he was appointed professor of history at Wittenberg, but as he refused to subscribe the *formula concordantiae* he was unable to retain his office. From 1589 to 1593 he taught at Rostock, after which he went to Heidelberg, where in 1602 he was appointed librarian to the university. He died at Heidelberg, September 20, 1627. The chief service rendered by Gruter to classical learning was in the department of inscriptions, his principal work on which is *Inscriptiones antiquae totius et Romani*, in 2 vols., Heidelberg, 1603. He also published editions of most of the Latin classics, but as his critical faculty bore little proportion to his erudition these are of small value.

GRUYÈRE, or GUYLERS (German, *Geyers*), is a small pastoral district in the Swiss canton of Fribourg, noted for its cheese (see *CHÉVRES* and *FAMBROUS*), which was at one time separate cantons. It forms part of the basin of the Saane. The old town of Gruyère, where the counts had their castle, had only 1097 inhabitants according to the census of 1870, while the neighbouring town of Bulle had 2274. There is no mention by that name of the counts or countship of Gruyère in any document previous to the 12th century, but the same family with the title of count of Ogo, *et*, Hochgrün, have been traced, though not without interruption, as far back as 923. The new designation was due, it would appear, to the fact that the counts of Ogo had held the post of *guyard* (guyard) or warden of the woods and forests to one of the later kings of Burgundy, the name of office, as in the case of the Scotch Stewarts, gradually passing into a regular family name. The counts of Gruyère were for the most part a vigorous and warlike line, and their banner, with the figure of a *grue* or crane, was not only a familiar object in the local conflicts of Savoy and Switzerland but saw good service in distant fields. Their last representative died in exile, his possessions having been seized by his creditors and sold to Bern in 1564.

The fortunes of the house are related with much detail in Hicly's *Histoire du Comté de Gruyère*, which occupies vols. ix., x., and xi. of the *Mémoires de la Société d'histoire de la Suisse Romande*, Lausanne, 1838, &c. See also Bonnetton, *Dietsch-ober ein Schweizer* (Basle, Switzerland, Bazel, 1782), H. Chwiler, *Comté de Gruyère*, Paris, 1826.

GRYNÆUS, or GRYNÆR, JOHANN JAKOB (1540-1617), a learned theologian of the period immediately succeeding the Reformation, was born, October 1, 1540, at Bern, where his father Thomas, nephew of Simon Grynaeus, was at that time a teacher of theology, was educated at Basel, and in 1559 received an appointment as errand to his father who had become pastor of Röteln in Baden. In 1563 he proceeded to Tübingen for the purpose of completing his theological studies, and in 1569 he returned to Röteln as successor to his father. Here, as the result of much reading and reflection, he felt compelled to abjure the Lutheran doctrine of the Lord's Supper, and to renounce the *Formula Concordantiae*. Called in 1575 to the chair of Old Testament exegesis at Basel, he became involved in unpleasant controversy with Simon Sulzer and other champions of Lutheran orthodoxy, and in 1584 he

was glad to accept an invitation to Heidelberg, where two years were spent. Returning to Basel in 1586 as anticleric or superintendent of the church there, he excited for upwards of twenty-five years a very considerable influence upon both the church and the state affairs of that community, and acquired a wide reputation as a skillful theologian of the school of Zwingle. Five years before his death, which occurred August 13, 1617, he had the misfortune to become totally blind, but he continued to preach and lecture to the last.

His numerous works include commentaries on various books of the Old and New Testament, *Thesaurus theologicus et philologicus* (1593), and a collection of private law, *the critical Monimenta et Fidei in Oratoriam* (2 vols. fol., 1599).

GRYNÆUS, SIMON (1493-1541), a learned theologian of the Reformation, was born in 1493 at Veltingen, in his fourteenth year was sent to school at Pfalzheim, and subsequently studied at the university of Vienna, where he graduated as master of arts, and for some time acted as tutor. He next became rector of a school at Ofen (Budapest), but as an avowed sympathizer with Reuchlin and Erasmus he was not permitted by the Dominicans to retain this post long. After an interval spent at Wittenberg with his old school friend Melancthon, he became professor of Greek in the university of Heidelberg in 1523, with the duties of this post he in 1526 combined those also of the Latin chair. In 1529 the friendship of Geoplampius obtained for him a call to Basel as successor of Erasmus, the completely disorganized state of the university at that time gave him abundant leisure not only for private study but also for a tour to England, where he charged himself with the task of obtaining the opinions of the Reformed theologians upon the subject of the king's divorce. On his return to Basel in 1531, the year of the death both of Zwingle and of Geoplampius, he began as theological professor to give exegetical lectures on the New Testament, and in 1531 he was summoned by Duke Ulrich of Württemberg to assist in the reformation there, and especially in the reorganization of the university of Tübingen. In 1536 he took an active part in the forming of the first Helvetic confession, and also in the conferences held with the purpose of inducing the Swiss to accept the concord of Wittenberg, which had also been drawn up in that year. He was the sole representative of the Swiss churches at the conference of Worms in 1540. His death took place suddenly at Basel on August 1, 1541. In Greek philology Grynæus was one of the first scholars of his day. In theology he was more of a theologian than of a practical man, but his profound erudition and angularly penetrating judgment gave him great influence among the more active spirits of the time. In literature his chief contributions were translations into Latin of Plutarch, Aristotle, and Chrysostom. See Struven's *Simonis Grynæi Epistolæ* (1817), whence a full list of his works is given.

GRYPHIUS, ANDREAS (1616-1664), German poet, was born at Grossglogau, Silesia, on the 11th of October, 1616. His youth fell in the period of the Thirty Years' War, which began in 1618, when he was two years old. After spending five years at school in various towns, he returned to his native place in 1636, and became tutor in the family of Palgrave George von Schönborn, who crowned him laureate and granted him a patent of nobility. In 1638 he went to the university of Leyden, where he spent six years, at first as a student, afterwards as a tutor. Having travelled through France and Italy in association with a young Pomeranian, and lived a year in Strasbourg, he went back to Silesia, and in 1650, at the age of thirty-four, was made syndic of the principality of Glogau. This office, the duties of which he faithfully discharged, he held till his death in 1664. He was a man of deeply melancholy

temperament, and his natural tendencies were fostered both by private misfortune and by the terrible public calamities of his age. Like most German writers in the first half of the 17th century, he was profoundly influenced by the critical doctrines of Opitz, on which account he is usually classed with the first Silesian school, although by some of his characteristics he is more closely allied to the second Silesian school. His best works are his comedies, one of which, *Peter Sphen*, is based on the comic episode of *A Midsummer Night's Dream*. *Die geliebte Doctoresse* (The Beloved Willdore), which is written in a Silesian dialect, contains many touches of natural simplicity and grace, and still ranks high among the comparatively small number of genuine comedies of which German literature can boast. *Der schlaue Soldat* is a rather laboured attack on pedantry. Besides these three comedies, Gryphus wrote five tragedies. In all of them his tendency is to become wild and bombastic, but he had the merit of at least attempting to work out artistically conceived plans, and there are occasional flashes both of passion and of imagination. His models seem to have been Seneca, and the great Dutch poet Vondel. He had the courage, in *Calisto Struud*, to deal with events of his own day, his other tragedies are *Leo Arminius*, *Katharina von Georgien*, *Cassiope* and *Celinde*, and *Pamphilius*. The lyrics of Gryphus give utterance to his despairing views of life, and are not without power, but it is as a dramatist that he is mainly important. No German dramatist writes before him had risen to so high a level, nor had he worthy successors until about the middle of the 18th century. A selection from his lyrics will be found in W. Müller's *Bibliothek der deutschen Dichter des 17ten Jahrhunderts* (Bd 2), and a selection from his dramatic writings in Tittmann's *Deutsche Dichter des 17ten Jahrhunderts*.

See Kloppe, *Andreas Gryphus als Dramatiker* (1851), and Hermann, *Andreas Gryphus* (1871).

GUACHARO,¹ the Spanish-American name of what English writers have lately taken to calling the ORN-BIRD, the *Strates nas capensis* of ornithologists, a very remarkable bird, first described by Alexander von Humboldt (*Voy aux Reg. Equinoxiales*, i. p. 413, Engl. transl., ii. p. 119, *Orn. Zoologie*, ii. p. 141, pl. xiv) from his own observation and from examples obtained by Bonpland, on the visit of those two travellers, in September 1799, to a cave near Caripé (at that time a monastery of Aisgonese Capuchins) in the Venezuelan province of Cumana on the northern coast of South America. A few years later it was discovered, says Latham (*Gen. Hist. Birds*, 1825, vii. p. 505), to inhabit Trinidad, where it appears to beat the name of *Dacotina*,² and much more recently, by the receipt of specimens procured at Sarayven in Ecuador, Chimacina in the Peruvian Andes, and Antioquia in New Grenada (*Proc. Zool. Society*, 1878, pp. 139, 140, 1879, p. 532), its range has been shown to be much greater than had been supposed. The singularity of its structure, its curious habits, and its peculiar economical value have naturally attracted no little attention, and it has formed the subject of investigation by a considerable number of zoologists both British and foreign. First referring it to the genus *Caprimulgus*, its original describer soon saw that it was in no wise Guatoucker. It was subsequently separated as forming a Subfamily, and has at last been regarded as the type of a distinct Family, *Stratesinidae*—a view which, though not put forth till 1870 (*Zool. Record*, vi. p. 67), seems now to be generally deemed correct. Its systematic position, however, can scarcely be considered settled, for though on the whole its predominant

alliance may be with the *Caprimulgidae*, nearly as much affinity may be traced to the *Strigidae*, while it possesses some characters in which it differs from both (*Proc. Zool. Society*, 1873, pp. 526–535). About as big as a Crow, its plumage exhibits the blended tints of chocolate colour and grey, banded and pencilled with dark brown or black, and spotted in places with white, that prevail in the two families just named. The beak is hard, strong, and deeply notched, the nostrils are prominent, and the gape is furnished with twelve long hairs on each side. The legs and toes are comparatively feeble, but the wings are large. In habits the Guacharo is wholly nocturnal, slumbering by day in deep and dark caverns which it frequents in vast numbers. Towards evening it issues itself, and with croaking and clattering which has been likened to that of crickets, it approaches the exit of its retreat, whence at nightfall it issues in search of its food, which, so far as is known, consists entirely of only nuts or fruits, belonging especially to the genera *Achras*, *Aspidnema*, *Laurus*, and *Psychotria*, some of them sought, it would seem, at a very great distance, for M. Funck (*Bull. Acad. Sc. Bruxelles*, ii. pt. 2, pp. 371–377) states that in the stomach of one he obtained at Caripé he found the seed of a tree which he believed did not grow nearer than 80 leagues. The hard, indigestible seeds swallowed by the Guacharo are found in quantities on the floor and the ledge of the caverns it frequents, whence many of them for some vegetable, the plants thus growing being etiolated from want of light, and, according to travellers, forming a singular feature of the gloomy scene which these places present. The Guacharo is said to build a bowl-like nest of clay, in which it lays from two to four white eggs, with a smooth but lustrous surface, resembling those of some Owls. The young soon after they are hatched become a perfect mass of fat, and while yet in the nest are sought by the Indians, who at Caripé, and perhaps elsewhere, make a special business of taking them and extracting the oil they contain. This is done about mid summer, when by the aid of torches and long poles many thousands of the young birds are slaughtered, while their parents in alarm and rage hover over the destroyers' heads, uttering harsh and deafening cries. The grease is melted over a fire kindled at the cavern's mouth, run into earthen pots, and preserved for use in cooking as well as for the lighting of lamps. It is said to be pure and limpid, free from any disagreeable taste or smell, and capable of being kept for a year without turning rancid. In Trinidad the young are esteemed a great delicacy for the table by many, though some persons object to their peculiar scent, which, says Lottand (*Des. de la Z. Trinidad*, p. 68) resembles that of a Cockroach (*Blattella*), and consequently refuse to eat them. The old birds also, according to Mr. E. O. Taylor (*Ibis*, 1864, p. 90) have a strong Crow-like odour. But one species of the genus *Strates* is known.

In addition to the works above quoted valuable information about this curious bird may be found under the following references:—L'Hermite, *Ann. Sc. Nat.*, 1836, p. 80, and *Nouv. Ann. Mus.*, 1838, p. 321, Hauteville, *Ann. Zool.*, 1838, p. 104, J. Müller, *Monist. Ber. Acad.*, 1841, p. 178, and *Archiv. Naturg.*, 1841, p. 1–11. Des Mus., *Rev. Zool.*, 1848, p. 83, and *Orn. Orn.*, pp. 260–263, Blanchard, *Ann. Mus.*, 1850, xi. pl. 4, fig. 80, König-Warthausen, *Journ. Zool. Orn.*, 1865, pp. 384–387, Goering, *Vergessene*, 1869, pp. 124–128, Murie, *Ibis*, 1870, pp. 21–26. (A. N.)

GUACO, HUACO, or GUAO, also YEUOCO and YEUOCO, terms applied to various Central and South American and West Indian plants, is reputed for alexipharmic and curative virtues. The Indians and negroes of New Granada believe the plants known to them as guaco to have been so named after a species of kite, thus designated in imitation of its cry, which they say attracts to it the snakes that serve it principally for food, they further hold the tradition that their antidotal qualities were discovered through the obser-

¹ This is said to be an obsolete Spanish word signifying one that cries, moans, or laments loudly.

² Not to be confused with the bird so called in the French Antilles, which is a Petrel (*Pterodroma*).

vation that the bird eats of their leaves, and even spreads the juice of the same on its wings, during contact with its prey. The disputes that have arisen as to what is "the true guaco" are to be attributed mainly to the fact that the names of the American Indians for all natural objects are generic, and that genera not always in coincidence with those of naturalists. Thus any twining plant with a heart-shaped leaf, white and green above and purple beneath, is called by them guaco (R Spruce, in Howard's *Neuewa Quinolagus*, "Cinchona succubua," p 23, note). What is most commonly recognized in New Granada as guaco, or *Pejuco del guaco*, would appear to be the *Mikania Guaco* of Humboldt and Bonpland (*Pl. Equinox.*, ii 86, pl 106, 1809, D C, *Prod.*, v 193), a climbing Composite plant of the tribe *Eupatoriaceae*, affecting moist and shady situations, and having a much-branched and deep growing root, variegated, sometimes, opposite leaves, and dull-white flowers, in axillary corymbs. The whole plant emits a disagreeable odour. J Faud (*Journal de Pharm.*, xii 281, 1836) obtained from leaves of a Mexican guaco, besides a wax-like matter, a substance analogous to tannin, and other bodies, a light brown bitter resin, *guaco*, soluble in alcohol and partly so in water, and stated by Pettenkofer to possess emetic properties, and to give off an intoxicating odour when titrated with sulphuric acid (Watts, *Diet. of Chem.*, i 945). Guaco has been highly recommended for the treatment of bites of venomous reptiles and insects, and in cholera, chronic dysentery, gonorrhoea and syphilitic affections, acute deafness, albumen, catarrhs, spasmus, gout, and other complaints. Its efficacy against poisoning by snakes, first carefully experimented on by Mutis¹ about 1787, has been frequently since attested, and in parts of New Granada much infested by those pests, a kind of inoculation with it is practised by some persons, the juice of the leaves being applied, at intervals of a fortnight during several months, to incisions in the hands, feet, and sides of the chest, two large teaspoonfuls of the same juice having beforehand been administered internally.² It is stated that the Indians of Central America, after having "guasonized" themselves, i. e., taken guaco, catch with impunity the most dangerous snakes, which writhle in their hands as though touched by a hot iron (B Seemann, *Travels in Jour. of Bot.*, v 76, 1853). The odour alone of guaco has been said to cause in snakes a state of stupor and torpidity, and Humboldt, who observed that the near approach of a rod steeped in guaco juice was obnoxious to the venomous *Coluber colubinus*, was of opinion that inoculation with it imparts to the perspiration an odour which makes reptiles unwilling to bite.

The *huaco hembra* and *huaco macho* of Mexico are the species *Mikania angustata* and *M. repens*, L. f., respectively. Among the best remedies for snake bites, according to Mercuri (*Revue*, i 279, 1828, *Syst. Mat. Med. Span.*, p 44, 1818), is the recently discovered juice of *Euphorbia asperginea*, Ventenat (D C, *Prod.*, v 109), a native of the Americas. On the Chimbozo mountains the esteemed guaco is an *Arctostaphylos*, distinguished often as *guaco del monte* from the Mikania, or *guaco del rancho*, so called from their failing about stable and denoted "chacra." A similar plant, with highly aromatic roots and leaves, is a native of Cartagena, *Machaonia huaco*, or *male vino*. The guaco denominated in the Peruvian Andes *bujeco* (climber) *de la estrella*, and *contrayerva* (cousin-bear, or antidote) *de bergas*, is the *Arctostaphylos fragrans* Gauss. of Ruiz (Hornem., *luc.*, p 9, D C, *Prod.*, v, p 1, 463). The tubercle of the root and stem of a Mexican guaco (Pharm. Society's Coll., 4972), also an *Arctostaphylos*, is administered in hydropneumonia. Among allied species accredited with the properties of guaco are *A. americana* L., a native of Cartagena, a Colombian, *A. cymifolia*, Mart., *A. macrocarpa*, Gomer, *A. trilobata* L., *A. sempervirens* L., supposed to be the plant with which

the Egyptian *angelica* stupely snakes, *A. Serpentina* L., or *Tu gauru* snake root, *Asarum canadense* L., the Canada snake root, or "wild ginger," and *Asarum virginicum*, Willd. The guaco of *abel* of F. Penna is the species *Crataegus dependula*, D C, *Prod.*, v 11, p 197, 1827, by the Mexican Indians. In the West Indies and Mexico *Convolvulus dactyloides*, Juss., is employed as guaco, *C. integrifolia* L., the *brésil* of some authors, resembles it in properties. According to R Otto (*Recherches sur les plantes de Cuba*, &c., pp 75, 76, 1848), *C. dactyloides*, Swartz, a small tree with cævose (b) novous sap, is the guaco of Trinidad in Cuba, where it is used in cholera and yellow fever.

Bonnier, *Notice sur le Guaco*, &c., 1868.

GUADALAJARA, a province of Spain, in New Castle, bounded on the N by the provinces of Segovia, Soria, and Saragossa, on the E by Saragossa and Teuel, on the S by Cuenca, and on the W by Madrid. In the north are some of the loftiest summits of the Guadarrama range, having their culminating point in the Peña de la Bodea, the rest of the province, forming the upper basin of the Tagus, and watered by its affluents the Alhambra, Tujuna, Hcnales, and Jarama, is comparatively level. The soil varies considerably, but is generally of a good character. Pistio occupies the larger part of the surface on the higher tract, and the mountains, though unduly denuded, still bear considerable masses of oak and cork. The plain around Tamejon is specially adapted for cereals, and the neighbourhood of Alcaniz matures all kinds of crops proper to the latitude. Iron and lead are the only minerals, the former in very abundant and has been worked from the remotest periods, the latter occurs but in small quantities. The principal productions are wheat, barley, oil, wine, silk, saffron, and flax, but the chief wealth of the province consists in sheep and wool. Manufactures and trade have been declining for many years. The province is divided into nine administrative districts, but besides Guadalajara, the capital, it has no town of importance except the episcopal see of Sigüenza. The area is 4809 English square miles, and in 1870 the estimated population was 258,638.

GUADALAJARA, a city of Spain, capital of the province of the same name, is situated on an elevation not far from the eastern bank of the river Henares, which is here spanned by a stone bridge built on Roman foundations in 1758. It is a station on the Madrid and Saragossa Railway, 38 miles N. E. from Madrid and 2395 feet above the level of the sea. It has ten churches, several convents, including that of San Francisco, founded originally by Doña Berenguela for the Templars in 1200, handsome town and county buildings (cassa consistoriales) built in 1835, and a college of engineers, besides the usual hospitals, barracks, and schools. There is also a fine palace of the ducal house del Infantado, built in 1481, and the Pantoon or burying place of the dukes of Mendoza, begun in 1696 and finished in 1799 at a cost of £160,000, rivals in the richness the tombs of the Escorial. An extensive Roman sewer discharges public fountains, and there are four alamedas or promenades. The principal manufactures are soap, earthenware, and woollens. The cloth manufacture, which was

¹ Mutis's plant is believed by N. Pateol to have probably been the above mentioned *Arctostaphylos Guaco*, and not, as supposed by Guillemin, the *Splachnites alvula* of Kunth, called guaco in Central America.

² According to R. Otto (*Observations on Brit. Guiana*, p 24, 1856), the operation is not of Indian origin.

formerly called on in behalf of the Government, is now in private hands. The mode of the place is chiefly in grain, flax, fruit, cloth, and silk. Population, 7900. Guadalupe is the Atirra or Cañon of the Romans, when taken by the invading Moors it was called Wada-l-hajarah (the river of stones), of which its present name (sometimes in the medieval chronicles spelt Godelfaire) is a corruption. It was recaptured in the days of the Cid.

GUADALAJARA, or in the older spelling GUADALAJARA, a city of Mexico, the capital of the state of Jalisco, is situated in the Atemareque valley not far from the Rio Grande de Santiago, about 280 miles W N W of the city of Mexico, in 20° 41' 10" N lat and 103° 21' 15" W long. Owing to its considerable elevation above the sea level (according to the *Boletín del Ministerio de Fomento*, 1876, 1652 metres, but according to older authorities 1580 metres), Guadalupe enjoys an excellent climate. On the whole it is well laid out, and its streets are kept in tolerably good condition. All the houses, whether built of stone, brick, or adobe, are plastered and whitewashed, and hardly a dozen of them attain the height of three stories. In the outskirts of the town the buildings are of an inferior type. The Plaza Mayor is a square about 300 feet in each direction, one side of which is occupied by the cathedral, another side by the *casa de gobierno del estado* or state buildings, and the remaining sides by *posadas* or inns in the shelter of which are some of the main shops of the city. The cathedral, commenced in 1871 and finished in 1878, is a rather fine structure with two steeples and a large dome between them covered with figures in coloured tiles. The interior is gloomy but impressive. No small interest attaches to the Hospital de San Miguel de Belen, which comprises, not only a hospital proper with male and female wards, but a lunatic asylum and a school for little children. Contiguous to it is the principal cemetery of the city, which is arranged in rather an unusual fashion. Three sides of the area are bounded by walls and colonnades, and the inner surface of the walls is divided into by means of niches or *queros* in which the dead are deposited. Another remarkable institution is the hospicio, occupying twenty-four large blocks of building, and not only affording an asylum for foundlings and orphans, for the blind, the deaf and dumb, and the infirm of all ages, for old people unable to secure a livelihood, but also serving as a reformatory and training school. It presents a fine appearance with its dome and pillared portico. Its inmates number upwards of 1000, 700 being children, and 300 old men and women. Among the other public buildings and institutions of Guadalupe are the university (formerly the Jesuit college), eleven conventual establishments, a theological seminary, an academy for the fine arts, a mint, a theatre, and a building. The favourite promenade is the *paseo* which runs for a mile and a quarter through the city, and terminates northward in the *alameda* or public garden. Guadalupe is a fairly busy town, with paper-mills and woollen and cotton factories, but all the principal establishments are in the hands of Frenchmen, Germans, or Englishmen. The confectionery of the town is held in high repute, and the Indians of the neighbourhood are remarkable for the artistic ability with which they mould figures in clay or rags. The silk embroidery produced in the hospicio is also worthy of mention. Guadalupe was founded in 1681 by Nùñez Guzman, and was made a bishop's see in 1849. The population, which was only 19,500 in 1860, had increased to 46,804 by 1841, and to 70,947 by 1870. At Puente Grande in the neighbourhood, the Rio Grande forms a magnificent waterfall, and the bridge of Calderon is famous for the defeat of the insurgents under Hidalgo in June 1811. Several excellent views of Guadalupe may be found in Geiger, *A Peep at Mexico*. On the 11th of March 1875 Guadalupe was visited by a

severe earthquake, which did damage to nearly every large building in the town. An account of the visit of Guadalupe, founded in 1811, is given in *Del So de geogr de la rep Mexicana* for 1871. In 1877 the value of the new coin was 1,467,660 pasties or dollars, 5000 pasties being in copper and the rest in silver. New machinery driven by steam was imported from France in 1878. The total import trade of the town was reckoned at 3,280,000 pasties in 1878,—Great Britain having about 40 per cent of the amount, France 25 per cent, the United States 10, and Germany 8. Full details on the money transactions of the city will be found in the *Procesosches Handelsjahr*, 1879.

GUADELOUPE, an island of the Antilles in the West Indies, belonging to France, is situated 62 miles from Martinique, between 15° 39' 30" and 16° 20' 18" N lat and between 61° 31' 33" and 61° 50' 32" W long. The sailing distance from Brest is 3750 nautical miles. A narrow channel, called La Rivière Salee, or Salt Stream, with a width of from 100 to 400 feet, separates the island into two portions, Guadeloupe proper or Basse Terre and Grande Terre. The former or western portion measures 28 miles from N to S, and from 12 to 15 miles from E to W, and its coast-line is estimated at 87 miles. The latter or eastern portion measures 23 miles from N to S and 34 from S E to N W, and its coast line is estimated at 106 miles. Basse Terre has a mountainous surface of volcanic origin, attaining its greatest altitude in La Soufrière, a still active volcano, 4870 feet in height, while Grande Terre is generally flat, with no elevations higher than 115 feet, and consists entirely of calcareous formations. In the rainy season the streams are subject to floods or "spates," which, according to M Caspion (*Rev Mar et Coloniale*, 1871), come on so suddenly that it is hardly safe to travel in the dry beds, lest, to use the local phrase, the *galien* descend. Basse Terre, as is natural, is traversed by a considerable number of streams,—the Goyave, the Léandre, the Moustie, the Petite Goyave, the Sainte Marie, the Trou au Chien, the Capiteux, &c.—while Grande Terre is almost destitute of springs, and both men and cattle are dependent for their water supply on the ponds and marshes. The mean temperature of the island is 79° Fahr,—the maximum in the shade ranging from 88° to 91°, and the minimum from 68° to 72° in July, August, and September are the hottest months. At Basse Terre, about 180 feet above the sea-level, the thermometer in July shows a mean of 80.8° Fahr, in August 82°, and in September 82°. Like the rest of the West Indian islands, Guadeloupe is subject to terrible storms. That of 1825 almost entirely destroyed the town of Basse Terre, and that of 1805 proved equally disastrous to Grand Bourg. The rainfall is very heavy, on the coast no less than 86 inches per annum. Along with its dependence, the smaller islands of Marie Galante, D'Amboise, and Les Saintes, Guadeloupe forms a separate colonial government. The following table gives the area of the several portions.—

	Hectares	Acres
Guadeloupe or Basse Terre	94,631	238,844
Grande Terre	65,631	163,181
Marie Galante	14,827	37,067
D'Amboise	2,730	6,720
Les Saintes	1,423	3,514
Petite Terre	343	848
Saint Martin (French portion)	5,177	12,776
Total	184,821	456,949

Of the total area 85,248 acres were under cultivation in 1873, 1932 acres were latites or cattle-farms, 30,610 acres savannahs, and 106,258 acres woods and forests, while 69,689 acres were fallow. To the sugar cane, which is the staple of the colony, 46,711 acres were devoted, to coffee, 8659 acres, to cotton, 1855 acres, to cocoa, 1146 acres,

to cocoa or anatto, 1632 acres, and to tobacco, 291 acres. Maize, which forms one of the principal sources of food in the colony, occupied 1,014 acres, and 11,946 acres were assigned to other articles of direct consumption. In the same year (1873) it was calculated that 43,780 people were employed in the sugar plantations, 5160 in the coffee plantations, 504 in the cotton plantations, and 1088 in the cocoa plantations. The whole value of the ground is stated at about £200,000, of the buildings and plants at £1,660,000, and of the live stock at £263,200. The total produce of sugar of all kinds was 679,300 cwts, the syrup and molasses amounted to 568,326 gallons, and the tafia or rum to 293,850 gallons. The produce of coffee, cocoa, and cocoa was respectively 13,564, 2102, and 10,663 cwts. The maize or cassava amounted to 282,412 cwts, and the other food substances, such as yams, bananas, arrowroot, &c., to 118,340 cwts. Tobacco, vanilla, and cloves were also produced in small quantity, as well as 4512 cwts of campeachy wood. The value of the whole was estimated at £1,134,220, and the net value at £298,437. Administratively the colony is divided into three arrondissements of Basse Terre, Pointe à Pitre, and Maité Galante. The town of Basse Terre, situated in 15° 59' 30" N lat and 66° 24' 31" W long, with a population of 12,000, is the capital, and the seat of the bishopric, which was founded in 1850, and Pointe à Pitre, situated in 16° 14' 12" N lat and 66° 13' 41" W long, and containing a population of 16,000, is the principal port. A fine military suburb, popularly known as the Gibraltar of the Antilles, is situated in the group of Les Saintes. There is a militia, originally constituted in 1832, partly dissolved in 1851, and is established in 1870.

During the twenty-five years from 1848 to 1872 the population of the colony remained almost stationary, the mean being only 132,000. Between 1873 and 1875 there was a notable increase, the mean for these years being 141,000. Owing probably to the influence of immigration, the masculine element is on the increase,—these being now 93 men to 100 women instead of 90 as formerly. Married people form only 20 per cent of the population. According to Dr Charles Waltham, with every 1000 European immigrants in 1864 there were introduced 25 women, for every 1000 Africans, 496 women, for every 1000 Indians, 253, and for every 1000 Chinese, 9. Between 1815 and 1872 there have been 30 births to every 1000 of the population, except during the five years from 1863 to 1867 when the ratio was only 27.6. If the non-reproductive part of the population be excluded, the births range from 41 to 48 per 1000, while in England the corresponding number is 61. It is estimated that probably 25 per cent of the births are illegitimate. During the years from 1848 to 1852, immediately after the abolition of slavery, there were a great many marriages, especially among the liberated population—no man indeed as 2000 per annum, but to use the words of Dr Key, "cette belle ardeur matrimoniale" soon came to an end. In 1870, 1871, and 1872 there were only three marriages to 1000 inhabitants.

Discovery—Guadeloupe was discovered by Columbus in 1483, and received its name in honour of Santa Maria de Guadalupe in Bete Madina in Spain. In 1634 Oliver and Duplessis took possession of the island in the name of the French Company of the Islands of America, and after Duplessis's death about six months later L'Olive engaged in a war of extermination against the Carib inhabitant. In 1774 Guadeloupe was united to the dominions of the crown, and for a long time it remained a dependency of Martinique. Successful insurrections were made to attack it by the English in 1666, 1691, and 1703, but on 27th April 1759 the inhabitants capitulated to Admiral Knowles and General Boscawen, and the island was handed to British possession till 1788. On 23rd April 1782 the French under Admiral de Guise were defeated by Rodney in the neighbourhood of the island. In 1778 Guadeloupe was finally captured from Martinique, but it remained in the common authority of the governor-general of the Windward Islands. The English under Sir

John Grey and John Jervis obtained possession on 21st April 1794, but they were expelled on the 2d of June by Clinton and Victor Hughes, commissioners of the National Convention, who were powerfully supported by the native population (see "Détresse de la Guadeloupe en 1794" in *Rev. Mar. et Col.* 1870). About this time the island contained about 107,526 inhabitants, and the commerce was worth £1,274,600. After the peace of Amiens the first colonial war expedition under General Rochambeau for the purpose of re-establishing slavery in Guadeloupe, but the negroes had actually defended that liberty for months. A new period of British possession was begun by the victory of February 8, 1810, and though by the treaty of March 1813 the island was made over to Sweden, and in the course of 1814 the French flag was again hoisted, it remained a temporary footing, in terms of the first peace of Paris, it was not till July 1816 that Britain finally withdrew her forces. Between 1816 and 1825 a special code of laws for Guadeloupe, enacted. Municipal institutions were introduced into the island in 1837 (November 20).

GUADIX, a city of Spain, in the province of Granada, situated on an elevated plateau on the northern slope of the Sierra Nevada, and above the left bank of the river Guadix. It is surrounded by ancient walls, and was formerly dominated by a Moorish castle, now ruins. It is said to have been the first episcopal see erected in Spain, it still is a bishopric, suffragan to Granada, but the episcopal see is architecturally unimportant. The town was once famous for its cutlery, but its modern manufactures (chiefly earthenware, hempen goods, and hats) are inconsiderable. It has some trade in wool, cotton, flax, corn, and liquors. The population is estimated at 10,150. The warm mineral springs of Grazna, much frequented by Spaniards during the summer season, are situated 4½ miles to the westward of Guadix, along with Almería and other places constituting the domain of El Zagal, was formerly surrendered without a siege to Ferdinand the Catholic in December 1489.

GUADUAS, a town of Colombia, South America, state of Cundinamarca, is situated in the beautiful valley of the Magdalena, on the road between Bogota and Ibadra, 45 miles N.W. of the former town, and more than 6000 feet above sea level. The name signifies in the original the bamboo cane, a plant which grows in great abundance in the neighbourhood. The town possesses a pretty church, and an old monastery now used as a prison. The staple articles of trade are sugar, coffee, cochineal, and oranges, and other fruits. The population is about 8000.

GUATAJUMA, a genus of trees of the natural order *Zygophyllaceae*. The gumtree or lignum vitae tree (Guaiac, *Guayabum*, *Fraxinosum*, *Pockmoh-bum*; Fr., *Guaiac*, *Guaiac*, *G. officinale*, L.) is a native of the West Indies and the north coast of South America, where it attains a height of 20 to 30 feet. Its branches are numerous, flaccid, and knotted, the leaves opposite and pinnate, with caducous stipules, and entire, glabrous, ovate or oval, flaccid, serrated in 2 or, more rarely, 3 parts, the flowers are in axillary cymes, and have 5 oval pubescent sepals, 5 distinct pale blue petals three times the length of the sepals, 10 stamens, and a 2-celled superior ovary, and the fruit is about ½ inch long, with a leathery pericarp, and contains in each of its two cells a single seed, *G. sanctum*, L., grows in the Bahamas and Cuba, and at Key West in Florida. It may be distinguished from *G. officinale* by its smaller and narrower

1 The guatajuma tree is described by Garayza de Hoff (Ann. bot. 3, 1854, 1855, fol.), as having yellow flowers.

GUALDO TADINO, a town of Italy, in the province of Perugia and circondato of Foligno, with a station on the line from Ancona to Rome about 58 miles from the former city. It is pretentiously situated in the lap of the Apennines on the post road that leads to the Fucio Pass. The cathedral and several of the other churches possess paintings by Nicolo and Matteo da Foligno of the 15th century. In 1871 the inhabitants of the commune numbered 7799. Gualdo has inherited the distinctive epithet of Tadino (which prevents it being confounded with Gualdo near Macerata, or Gualdo Cattaneo near Spoleto) from the ancient Roman town of Tadinum, the ruins of which, discovered in 1760, are situated in the vicinity, not far from the church of Sta Maria Tadina. It was near Tadinum that Narses gained his famous victory over Totila in 552. Recovering from the effects of the Gothic and Lombard invasions, the town, which even then was defended by walls, became for a time an independent commune, but it ultimately passed under the control of Perugia. In 1816 it was incorporated with the Roman States, and in 1833 it was made a city by Gregory XVI.

GUALEGUAY, a town of the Argentine republic, department of Entre-Rios, is situated on the Gualeguay river, which falls into the Parana, and is navigable up to this point, 120 miles NNW of Buenos Ayres. It is a prosperous and increasing town, and has an active shipping trade in beef, mutton, hides, wool, tallow, and timber. In 1874 the total value of exports was £268,970. The population is about 19,000.

GUALEGUAYCHO, a city of the Argentine republic, department of Entre-Rios, is situated on the Gualeguaycho river, which there falls into the Uruguay, 120 miles north of Buenos Ayres. Like Gualeguay, it depends for its prosperity chiefly on the sheep and cattle grazed in the neighbouring country, and its export trade includes beef, mutton, hides, wool, tallow, and bone manure. The total value of the exports in 1874 was £163,968. The population is about 20,000.

GUAMANGA See HUAMANGA

GUAN, a word apparently first introduced into the ornithologist's vocabulary about 1749 by Edwards,¹ who said that a bird he figured (*Nat. Hist. Uncommon Birds*, pl. xii) was "so called in the West Indies," and the name has since been generally applied to all the members of the Subfamily *Penelopina*, which are distinguished from the kindred Subfamily *Circus* or *Circus*es by the broad postacetabular area of the pelvis, as pointed out by Prof. Huxley (*Proc. Zool. Society*, 1868, p. 297), as well as by their maxilla being wider than it is high, with its culmen depressed, the crown feathered, and the nostrils bare—the last two characters separating the *Penelopina* from the *Oreophagina*, which form the third Subfamily of the *Circidae*,² a family belonging to that taxonomic division *Perisoreidae* of the Order *Columba*.

The *Penelopina* have been separated into seven genera, of

which *Penelope* and *Otalida* (properly *Otalus*), containing respectively about sixteen and nineteen species, are the largest, the others numbering from one to three only. Into their minute differences it would be useless to enter; nearly all have the throat bare of feathers, and from that of many of them hangs a wattle, but one form, *Chamaepetes*, has neither of these features, and *Stegodermis*, though wattled, has the throat clothed. With few exceptions the Guans are confined to the South-American continent, and one species of *Penelope* is however found in Mexico and at Mazatlan, *Penelope carolinensis*; subspecies *flavida*, as well as the mainland, while the species of *Otalus* occur in Mexico or Texas, and one, which is also common to Venezuela, in Tobago. Like *Circus*es, Guans are in great measure of arboreal habit. They also readily become tame, but all attempts to domesticate them in the full sense of the word have wholly failed, and the cases in which they have even been induced to breed and the young have been reared in confinement are very few.³ Yet it would seem that Guans and *Circus*es will interbreed with poultry (*Ibis*, 1866, p. 24, *Bull. Soc. Imp. d'acclimatation*, 1868, p. 559, 1869, p. 357), and what is more extraordinary is that in Texas the hybrids between the *Chamaepetes* (*Otalus vetula*) and the domestic Pouter are asserted to be fit superiors to ordinary Game cocks for fighting purposes. More information on this subject is very desirable. (N.)

GUANACO (*Acchena guanaco*), one of the four species of ruminant animals which represent in South America the camel of the East, and which resemble them in the possession of canine teeth in both lower and upper jaws. The Guanaco is the largest species, standing nearly 4 feet high at the shoulders. It is an elegant creature, with gracefully curved neck and long slender legs, its body is covered with long soft hair of a fawn colour above and almost pure white beneath. It is found throughout the southern half of South America, from Para in the north to Cape Horn in the south, but occurs in greatest abundance in Patagonia. It lives in herds usually of from six to thirty, although these occasionally contain several hundreds, while solitary individuals are sometimes met with. They are exceedingly timid, and therefore wary and difficult of approach, like many other ruminants, however, their curiosity sometimes overcomes their timidity, so as to bring them within range of the hunter's rifle. Their cry is peculiar, being described by Cunningham (*Natural History of the Strait of Magellan*, 1871) as something between the belling of a deer and the neigh of a horse. The chief enemies of the guanaco, according to the same authority, are the Patagonian Indians and the puma, as it forms the principal food of both. Its flesh is palatable although wanting in fat, while its skin forms the chief clothing material of the gigantic Patagonians.

According to Darwin, who studied it in its native wilds, the guanaco is readily domesticated, and in this state becomes very bold and will attack man, striking him from behind with both knees. In the wild state, however, they never seek to defend themselves, and if approached from different points, according to the Indian fashion of hunting them, they get completely bewildered and fall an easy prey. They take readily to the water, and have been observed swimming from one island to another, while Byron in his *Narrative* states that he has seen them drinking salt-water. They have a singular habit of dropping their dung during successive days on the same spot—a habit which is greatly appreciated by the Teuicuin Indians, who use these deposits for fuel. They seem also to have favourite localities.

¹ Edwards also gives "Quan" as an alternative spelling, and thus may have not the original form, since we find Dampier in 1678 writing (*Voy.*, ii. pt. 2, p. 95) of what is no doubt an allied if not the same bird as the "Quan." The species represented by Edwards does not seem to have been identified by the latter authorities.

² See the excellent *Synopsis*, extensively laid under contribution for this article, by Messrs. Sclater and Salvin in the *Proceedings of the Zoological Society for 1870* (pp. 554–561), while further information as to the *Circus*es has since been given by the former of these gentlemen in the *Transactions of the same society* (ix. pp. 273–288, pls. 21–23). Some additions have since been made to the knowledge of the family, but none of very great importance.

³ It would be hard to put too high upon the important bearings on the question of geographical distribution which the establishment of this division has tended to show. For this reference must be made to Prof. Huxley's original paper (see *supra*), or to the epitome of it given in the *Zoological Record* (v. pp. 34 and 59).

⁴ Cf. Dixon (*The Dove and the Aery*, pp. 223–273, London, 1857), who argues that the reported means of the Dutch towards the end of the last century in domesticating these birds was an exaggeration or altogether a mistake. His two chapters are well worth reading.

ties in which to die, as appears from the great heaps of bones bearing no sign of having been gnawed by the puma, which have been found in particular spots.

GUANAJUATO, or SANTA FE DE GUANAJUATO, a city of Mexico, capital of the state of Guanajuato, is situated in 21° 0' 50" N lat and 100° 51' 37" W long., at a height of 7200 feet above the sea. Built as it is at the meeting-place of these mountain gorges, and obliged by lack of space to climb the underfalls of the surrounding heights, Guanajuato has a highly picturesque appearance. The houses of the lower town are four or five stories in height, the most of the streets are narrow and tortuous, and the population is small though beautiful. The cathedral, the Jesuit church, the mint dating from 1813, the new theatre built in 1874, the university, and the gymnasium are worthy of mention. The Alhondiga de Hacienda, originally a coin magazine, was occupied as a fort in the War of Independence, and acquired peculiar interest as the spot where the patriot Hidalgo met his death. Guanajuato, founded in 1551, owed its existence and prosperity to the fact that it is the centre of the greatest silver-mining district in the world. Of the individual mines perhaps the most famous is the *Veneranda*, with a shaft 2000 feet deep, which is in process of being cleared of the water by which it has long been flooded. The population, which includes a considerable number of foreigners, formerly amounted to 100,000, but in 1860 was only 63,500.

GUANOVELICA. See *GUANAYELICA*.

GUANO. The deposits of guano, or *lucano*, known locally as *huancaya*, are found in characteristic condition and abundance upon a large number of the islands lying off Peru and upon certain parts of the mainland. They occur in Bolivia and to the north of Peru also, but are there generally poorer in quality, if not always less in quantity. For the production and preservation of good guano two conditions are requisite—a rainfall or nearly rainless climate and abundance of fish in the waters of the ocean. Both conditions are fulfilled on parts of the Bolivian and Peruvian coasts. The penguins, gannets, divers, cranes, cormorants, flamingoes, and other fish-eating birds thus find ample supplies of food, while their excreta retain their soluble and more valuable constituents. But even Peruvian guano is not exclusively excretations, nor wholly the produce of birds. These marine and maritime *huancayas* are the breeding-places, the roosts, and the excrement not only of sea-birds, but of many other sea-animals—scals, sea-hares, &c., frequenting many guano lands and islands, and adding considerably during life and when dead to the deposits. In Peruvian guano, it is true, the evidences of its origin are often obscure, but the somewhat complex sources of this material are well shown in the West African guano islands. On these Mr. T. R. Eiden found (1848) three varieties of guano, the lowest being a crust or rock guano, the next above this being a seal guano, containing much seal-fat, and the uppermost layer being a bird guano, in which there were many mummified bird skins and large quantities of feathers.

The dung of bats, which has been found in large quantities in many caverns, both in Europe and in certain parts of France, the Pyrenees and Italy, in New Zealand, and on the North American continent, has been designated "bat-guano". Further, the term guano, even when employed to describe the marine and maritime deposits previously mentioned, includes a considerable variety of substances very different in chemical composition and in manure value. For the deposits of guano occurring on the rainless or nearly rainless islands and coasts of Peru vary much in the proportion of their constituents, such variation being due less to differences in the origin of the deposit

than to subsequent changes. Exposure to the action of the sea and of seaweed, and the pressure of superincumbent layers, are without influence on the nature of the guano, very different qualities being found at different depths.

Although allusions to guano occur in the writings of travellers in the 17th and 18th centuries, the credit of directing the attention of Europe to this curious and useful product is due to Humboldt. In 1804 he brought from the Chincha Islands a specimen which Klaproth and then Poncey and Vauquelin analysed. But it was not until the publication in 1840 of Liebig's work on chemistry in its relations to agriculture and physiology, and demonstrated the importance of animal manures that a lively interest in this Peruvian fertilizer was awakened. In that year a firm of merchants of Lima sent a large cargo of guano to England, but it was not until 1842 that the regular trade in guano began. Messrs Gibbs & Co imported 182 tons in that year, while in 1862 the amount was no less than 433,000 tons. The price was lowest (£9 per ton) in 1848–9. It rose successively, in the years 1854 to 1856, from £10 to £13, and has since remained at about the last sum for the best qualities. Happily the Peruvian Guano Company are now prepared to sell this manure according to the results of analysis, and not before, at a fixed price irrespective of the variable qualities of different cargoes. Each unit per cent of nitrogen is set down as worth 19. 2d per ton, while the phosphates calculated as tri-calc phosphate, are reckoned as worth 3. 3d per unit per ton. The only drawback to this plan lies in the rather exaggerated price which it assigns to the low qualities of Peruvian guano, namely, those which are poor in nitrogen but rich in phosphates—containing perhaps 40 to 60 per cent of these compounds, which may be much more cheaply purchased in other forms. Still it cannot be urged that the phosphates of Peruvian guano are more useful than those from most other sources, on account of their physical condition, and their solubility. After all, however, the high phosphate guanos are not much appreciated by farmers, who prefer to use bones and superphosphates as manure for grass lands and root crops.

For a long time the group of Peruvian islands known as the Chincha furnished nearly all the guano that found its way to Europe. When these deposits, amounting to 7 million tons or more, were practically exhausted—only 150,000 tons of the best deposits remaining in 1872,—then further working was stopped except for use in Peru itself. Then the guano on the Mocha and Huancayo islands were exported to Europe, in four years (1870 to 1874) about 1 million tons having been shipped and about half a million tons remaining in 1875. Since then the Lobos islands, situated about 70 miles north of Mocha, have been worked, as have also the islands of the Ballistas group. Even in 1871 three-fourths of the cargoes of nitrogenous guano were from Huancayo, but the amount of nitrogen generally present in them was rather low, often not exceeding 10 per cent of "potential" ammonia, while the percentage of water was remarkably high—sometimes not less than 25 per cent. The Ballistas guanos of the same year were drier and contained one-third more nitrogen.

In spite of many testings and surveys, the amount of Peruvian guano still remaining to be exported has not been even approximately determined. Not only do contiguous deposits differ much in composition, but it is frequently impossible to ascertain what is guano and what is sand or rock. Sometimes the layers of guano are too thin to be worth removing, in other places they fill up ravines to a much greater depth than would be imagined. An estimate of the total quantity of Peruvian guano remaining in 1877

¹ This bat-guano generally contains much water (over 60 per cent) with about 5 per cent of phosphates, and is to 7 per cent ammonia.

² *The Art of Metals*, by A. A. Berthel, published in an English translation in 1870 in London, mentions guano from the following

gave over 2 million tons available for commerce, but this figure presumably includes all varieties, both nitrogenous and phosphatic. Most of the guano lately and now exported comes from the following groups of islands, or places on the coast—Macabi, Huamapa, Ballestas, Punta de Lobos, Pabellón de Fua, and Huamiles, and, since 1877, particularly from the last two localities.

In the article AGRICULTURE (vol. i p. 347) some statistics of guano imports were given. According to the British Consular Reports (1878, No. iv pp. 525-539) the quantities of Peruvian guano sold of late years were, in tons—

1869	571,790	1874	886,476
1870	461,601	1875	374,668
1871	468,200	1876	376,668
1872	402,097	1877	310,042
1878	342,425		

The amounts of Peruvian guano taken by different countries during 1876 and 1877 were as follows—

	1876	1877
England and her colonies	180,958	109,954
France and her colonies	109,165	72,067
Guamany	63,724	23,456
Belgium	45,340	71,478
Spain	26,859	28,456
Italy	8,564	6,140
Holland	1,077	5,628

In 1872, when the number of countries contributing guano was very large, the imports into the United Kingdom were as follows—

	Tons	Value
Peru	74,401	£1,400
Peru Islands	17,476	£1,400
Bolivia	14,068	£1,400
West Coast of Africa	26,859	£1,400
Dutch West Indies	1,562	£1,400
Brazil	1,232	£1,400

The following are amongst the more obvious characteristics of good Peruvian guano. Although at the present time it is by no means of uniform appearance or of constant composition, yet it may be stated that the best qualities, which most closely resemble the former supplies from the Chincha, are light in colour, do not weigh much more than 60 lb per bushel, are friable, and do not cohere strongly when pressed between the fingers. Small soft lumps are often observed in good samples, when these are broken a white or pale-coloured substance is seen in the centre. This lighter-coloured matter contains carbonate and other ammoniacal salts, in some adulterated samples its appearance is imitated by means of gypsum. The hard lumps found in guano are of very varying composition, some being highly phosphatic and others highly siliceous. The ash left on burning a good Peruvian guano is white or grey, a red ash generally indicates adulteration with oxide or ferruginous earth. An unusual proportion of water commonly points to damage by sea-water or rain, a kind of injury which is the more serious, since it is usually accompanied by a considerable loss of ammonia. If more than a mere trace of chlorine be found in a sample of guano, damage by sea water may be suspected. Although a good guano commonly contains more than half its weight of organic matter and of other substances driven off by a red heat, yet when a still larger quantity of such volatile matters is found their presence may be, and often is, a sign of adulteration with peat.

Guano has been often submitted to analysis,—much more frequently, however, for the sake of determining their general value than that of ascertaining the elements. The result is almost practically deposits, so far as analysis can show, upon their richness in nitrogen and phosphates. The nitrogen, we know, exists in several forms, of which urea, and other urates, with salts of ammonia (the nitrates, carbonates, and phosphates), are the most important. But besides these compounds a peculiar base or animal alkaloid known as guanino ($C_4H_5N_3O$) is present in most samples of Peruvian guano, it is not unlikely that the nitrogen of this body is captured and assimilated by plants. A considerable though variable quantity of nitrates and nitrates

has been recognized in some guanos, ranging, when expressed as potassium nitrate, from no more than $\frac{1}{10}$ per cent up to 5 and even 6 per cent. Other nitrogenous compounds present in these intermediate substances, which require further analysis, are oxides of bone, skin, cartilage, and keratin, and of the products of flesh. These intermediate products of decay are ultimately resolved into ammonia salts and nitrates. Some guanos, not only those of the West African coast (whereby a considerable number of the decomposed feathers, which cannot possibly yield their nitrogen to vegetation for some time. On this account less than half of the 8 to 12 per cent of so-called "potential" ammonia in these guanos is so effective as that in the guano of Peru. The phosphates of guano are numerous, including titanic, silicic, ammonio-magnesian, and ammonio-phosphates. The solubility of great part of the phosphates in guano helps to make its action more intense and immediate, as much as 10 to 15 per cent of phosphorus pentoxide has been found to be soluble in some instances. Such is said to be often the case with the guano of Tanganyika, Broken Island and Jarvis Island guanos. This solubility arises partly from the composition of the phosphates present, some of which are naturally readily soluble in ordinary water, but it arises partly also from the presence of ammonium oxide, by which the solubility of the calcareous phosphates is increased. The carbon dioxide which the decaying organic matter of guano continually evolves also aids in effecting the solution of these phosphates which are not soluble in pure water.

As a least part of the nitrogen of guano exists in the form of the volatile carbonates, it will be found that the most delicate analyses sometimes vary much on being kept. One sample of Chincha guano imported in 1865 contained nitrogen equal to 20.1 per cent of ammonia, of this 10.1 per cent was lost when the guano was exposed to the heat of boiling water, and 9.0 per cent when the sample was merely kept for a year in a provided condition in an ordinary bottle. With so strongly ammoniacal a guano as this, the fixation of the volatile nitrogenous compounds to urea or in acid is highly desirable. Oil of vitriol is employed in different proportions and in different ways for this purpose. About 5 or 6 lb of oil of vitriol diluted with water and mixed with sand or put in a bag added to each cwt of guano. Such a process was patented in 1849 by Dr Richardson of Newcastle. In this way the ammonia of the volatile carbonates is fixed in the form of sulphate, the oxides and phosphates of the guano remaining unaffected. But sometimes, as in the manufacture of "condensed" guano, a large quantity of oil of vitriol is used—very 25 to 30 lb to each cwt of raw guano. In this case a kind of rich superphosphate is obtained in which 20 per cent of the weight of "bone phosphoric acid" is present in association with nitrogen equal to 9 or 10 per cent of ammonia. Such a preparation is Oldfield's dissolved Peruvian guano, while "amphiphil" and "ammonia fixed" guanos contain less oil of vitriol, and generally some other substance like sulphuric acid, which reduces their concentration to a more easily digestible "phospho guano" is in reality a superphosphate made from MgO and other phosphoric guano, and caused by the addition of ammonium sulphate. This Oldfield's (Bolivian) guano contains about 1 per cent of nitrogen, and 6 per cent of ammonia. The guano is a term applied to the dried and prepared shingle or deposit obtained in the treatment of town sewage by the "A. R. C." process—one of the many precipitation processes now in use. It has little in common with true guano. Fresh guano is prepared chiefly from the refuse of the cod of the Newfoundland and New wagen fisheries. It is rich both in nitrogen and in phosphates, when containing 5 per cent of the former and 30 per cent of the latter, but its only action causes its action is assumed to be an action and also.

Although it is usual and convenient to classify guanos into two groups according to their richness in nitrogen or phosphates it is not really, there is no sharp line of demarcation between these classes. Indeed the guano from a single spot may show every gradation from nitrogenous to phosphatic. For instance, the samples taken from a deposit at Punta de Lobos gave amounts of nitrogen corresponding to the following percentages: 11.1, containing no several layers—surface, 81 per cent, middle, 41.5 per cent, deepest, 16.67 per cent. These samples from another working in the same mine gave these figures—8 per cent ammonia at 8 feet, 8 per cent at 20 feet, and 12 at 40 feet. A guano containing 12 per cent of potential ammonia, that is, containing an amount of nitrogen which, if expressed as ammonia, equals 12 parts in the hundred of guano, may be regarded as a satisfactory, but much more quantities of guano are now exported from Peru, containing no more than 8 or 10 per cent of ammonia. And these are lower qualities still, with 6 to 8 per cent of ammonia, and these pass into the class of phosphatic guanos, with but little organic matter and nitrogen, but from their solubility in water, and their capacity of being applied, without previous mechanical treatment, to the land. But when we are dealing with what are called "raw" or "crude" guanos, we not only have an almost complete absence of nitrogen and of organic matter, but the hard

ness of the material is such as to involve its being first ground and then tritured with oil of vitriol to turn it into a amorphous phosphate before it can become available as manure. With the highly phosphatic yet powdery and soft guanos of Peru and Bolivia such treatment is truly necessary, but it is essential with Navesina (Columbia S. A.) and with the Sonoma Island (Gulf of Mexico) guanos. The latter variety contains no nitroguano, and is very hard, but contains on an average no less than 75 per cent of kneaded phosphate. It has been said that the imports, this Great Britain of the Sonoma phosphate to have been no high, that the whole island has been trampled into this state.

Some notion of the main constituents of Peruvian and Bolivian guanos may be gathered from the following figures, which roughly represent the nature and percentage proportions of the chief constituents of five samples from several localities —

	Angamos	Chunchu	Pachilon de Peru	Punta de Lobos	Bolivia
Nitroguano	11	18	17	16	13
Organic matter and combined water	17	6	6	4	3
Whitish is nitrogen equal to ammonium	65	67	13	7	4
Thickened phosphate	10	2	10	20	42
Phosphoric acid	19	22	18	3	3
Alkalies, &c., by difference	0	6	12	13	12

This specimen of Angamos guano certainly contained 25 per cent of potential ammonium, and but 10 per cent phosphoric acid as triphosphate phosphate. It will indeed be seen how generally with the diminution of the nitrogenous organic matter the phosphates in crease, and vice versa. Analyses of guanos from many different countries exhibit this strange, but so constant, and so easily representative law. In all the phosphates in one might expect, owing to the intrusion of siliceous matter. In some guanos analysed by Berthelot more than 80 per cent of sand occurred. Californian guanos give the analysis of 10 per cent ammonium, and about 30 per cent phosphates. In Falkland Island guano he found about 2 to 28 per cent ammonium and 20 to 25 per cent phosphates. In the case of so variable a material it is hardly surprising to find individual specimens may average as low as 10 per cent, or as high as 25 per cent. But it is instructive to note how low a proportion of nitrogen is present in many of the guanos from different countries — Ango Bay, 5 per cent potential ammonium, Ascension Island, 6.0, Queensland, 1.0, Chili, 1.2, Ecuador, 5, Mexico, 4, Tala gonia, 2.7, Tasmania, 2.5.

In the guanos imported during 1817-48 Mr J. T. Way found the following average percentages of ammonium (calculated from total nitrogen) and of phosphates (calculated as triphosphate) —

	Ammonia	Phosphates
Peru (13 samples)	17.41	24.12
Chile (11 ")	7.40	30.80
Peru (11 ")	1.54	44.60
S. America (20 ")	1.62	66.40

Dr Voelcker's analyses of samples taken in 1874 from the Indian mentioned places gave about 25 per cent phosphates, and of ammonium 8 to 12 per cent in guanos from Pachilon de Peru, 8 to 12 per cent from Lobos, and 5 to 12 per cent from Huanillo de Peru.

The Lobos guanos, having since then become of generally inferior quality, have been but sparingly imported during the last few years. The percentage of ammonium in recent guanos of guano from Punta de Lobos has been 5 to 6, from Huanillo de Peru, 8, and from Pachilon de Peru 11 to 12.

The analysis of guano for commercial purposes is generally limited to the quantitative estimation of these constituents — the nitrogen, the soluble phosphoric pentoxide, and the insoluble phosphates, the latter usually reckoned as triphosphate. The processes of analysis require a few special precautions. One of these consists in making the guano in its original or unaltered state when making a nitrogenous determination by Will and Wanklyn's method, otherwise a loss of ammonium may occur.

As a manure the nitrogenous guano of Peru is rich, active, and stimulating. It is very tenderly to be used as a top-dressing, and as a development of foliage, and is therefore peculiarly fitted for application to grass and to other plants the development of the stem and leaf of which is desired. Its effects on clover are less marked. Mixed with superphosphate of lime, it is a valuable manure for corn, and to most of the plants of the kitchen garden, for many plants cultivated for their flowers it may be used also, but with great care and moderation, mixed with water or dry soil. On light and calcareous lands it is very apt to burn, and in such cases it has frequently been found to burn and destroy the young plants or even to prevent the germination of the seed. A dissolved guano is less liable to cause this injury.

Guano, with another very useful natural product, namely, nitrate of soda, constitutes the chief source of revenue for Peru.

The following papers and reports in the *Journal of the Royal Agricultural Society* contain interesting information on guano. See vol. ii p. 201, p. 186, xiv p. 186, set ii vol. i p. 218, v vol. i p. 142, 408, vi vol. i p. 220, vii vol. i p. 261, x 641. Native guano is discussed in vol. vi p. 425. The *Journal of the Royal Agricultural Society* contains a digest of most of the important papers on guano published on the Continent, see, e.g. 1868-9, pp. 281-288, 1869-70, pp. 180-181, 1869-70, pp. 160-167, 1867, p. 189, 1870-71, pp. 190-195, 1871-72, p. 10-20. A complete summary of the papers in 1874 by Dunlop & Co., London, gives some important statistics and reports on the Peruvian guano then remaining, as also does the Commercial Blue Book, No. 33, 1878, pp. 625 to 639. (A H C)

GUARANÁ, so called from the Guaranis, an aboriginal American tribe, the plant *Paulinia sorbilis*, Mart., of the natural order *Sapindaceae* and tribe *Sapindaceae*, indigenous to the north and west of Brazil. It has a smooth erect stem, large pinnate alternate leaves, composed of 5 oblong-oval leaflets, indurcescence in narrow panicles of short-stalked flowers, having 4 or 5 sepals and 4 petals, 8 stamens, and a cylindrical 3-celled ovary, and fruit ovoid or pyriform, about as large as a grape, and containing usually one seed only, which is shaped like a minute horse-chestnut. What is commonly known as guaraná, guaraná bread, or Brazilian cocoa, is prepared from the seeds as follows. In October and November, at which time they become ripe, the seeds are removed from their capsules, and sun-dried, so as to admit of the ready removal by hand of the white oil, they are next ground in a stone mortar or deep dish of hard stone, and the powder is then mixed with a small quantity of water, or by exposure to the dew, is then made into a paste with a certain proportion of whole or broken seeds, and worked up sometimes into balls, but usually into rolls not unlike Gorman snappers, 6 to 8 inches in length, and 12 to 10 or in weight. After drying by artificial or solar heat, the guaraná is packed between broad leaves in sacks or baskets. Thus prepared, it is of extreme hardness, and has a brown line, a bitter astringent taste, and an odour faintly resembling that of roasted coffee. An inferior kind, softer and of a lighter colour, is manufactured by admixture of cocoa or cassava. Keaped or grated into sugar and water, guaraná forms a beverage largely consumed in S. America. Its manufacture, originally confined to the Manabá Indians, has spread into various parts of Brazil.

The properties of guaraná as a nervous stimulant and restorative are due to the presence of what was described as a new principle, and termed *guaranine*, by Dr T. Blatter, but which was proved by Berthelot and Deschamps to consist of a new base, $C_{12}H_{19}O_2$, 1840, p. 518 &c. to be identical with *ergone* or *thamne*, $C_{12}H_{19}O_2$, 1840, p. 518 &c. This alkaloid guaranine yields 5.07 per cent, against 2.18 in good black tea, 8 to 12 in coffee beans, and 1.2 in that of Paraguay tea. *Pharmaceutical Journal*, vii p. 216. In medicinal purposes it may in fact be regarded as "a practically a convulsant form of impure caffeine." (F. E. Anstie, *Baillie's Dispensary*, 1874, p. 375). Besides this substance, which is stated to exist in it in the form of salts, guaranine yields on analysis the glucosidic sapogen, with tannin, starch, gum, three volatile oils, and an acid green fixed oil (Fouquier, *Journal de Pharm.*, vol. xxvii, 1861, p. 201).

A medicine, guaraná, was first described in 1817 by Cadiot de Gascogne, in whom a specimen was sent from Brazil (see *Ann. Gen. de Therap.*, lii, 1837, p. 497 &c.), in which country it is in popular repute as a stomachic, a hiccough, and aphrodisiac, and more especially as a specific for dysentery and diarrhoea, in which it is always given in very large doses — 8 to 10 grammes (*Quint. Gen. de Therap.*, liii p. 139). It is said by Martius (*Syst. Nat. Med. Phys. Brasiliensis*, p. 58, Leipzig, 1843) to diminish fever by its cooling effects on the nerves, to invigorate the stomach and intestines, to restrain excessive mucous discharges, to increase the action of the arteries and heart, and to promote diaphoresis. In migraine, or sick-headache, it has sometimes been found a most agreeable remedy. *Pharm. Journal*, xix p. 421 and 426, *Pharm.*, Aug and Sept 1873, pp. 100-102, 161-170, and it has been recommended in lumbago when the pain is of a stinging nature (Martius, *Drucke's Reise*, 1874, v p. 383), and in rheumatism.

See Euxine and Marone, *Revue de Brasiliens*, vol. iii p. 1061 and 1098, Munich, 1831, Hooker's *Journal of Botany*, vol. ii, 1861, p. 169-4, Bentley and Trimen, *Modernized Plants*, ii, 4, tab. 67, 1874, *Guaraná*, *Pharm. Journal*, 4th ser., xxi p. 224. On the "Antagonism" between Guaranae

and *Mcconato de Mophas*," see J. H. Bennett, *Rep on the Antiquity of Matheua*, p. 86, 1876. Further bibliographical references will be found in Prof. P. Montegraz's excellent article, "Del guarant, nuovo alimento nuovo," *Ann Univ di Mod*, April to June 1866, vol. 192, pp. 92-153.

GUARANTEE, or **GUARANTEE**, in English law, is a promise to be answerable for the debt of another should he fail to make payment, or generally to be answerable for the performance of any duty by another person. The debt or duty must be owing by another, who is primarily bound, and the guarantor is only liable in the event of his failure of performance. Guarantees are required to be in writing by the Statute of Frauds (29 Car II c 3), which enacts (§ 4) that "no action shall be brought whereby to charge the defendant upon any special promise to answer for the debt, default, or misbehavior of another, unless the agreement upon which such action shall be brought shall be in writing, signed by the parties to be charged by the contract, or some other person thereunto by him lawfully authorized." The test of the applicability of this section is whether the original debtor continues liable. If his liability is gone, and the person promising to pay the debt becomes immediately and primarily liable, then the promise need not be in writing. Thus when a debtor had been taken in execution for a debt, and a third person promised to pay the debt if the debtor were discharged from custody, it was held that writing was not necessary, inasmuch as the discharge operated as a satisfaction of the original debt, and the person making the promise alone remained liable. The default for which liability may be assumed by another person includes any case of breach of duty, and is not confined to cases of non-performance of contracts. A promise to guarantee comes under the general rule which requires enforceable agreements to be founded on consideration, i.e., a corresponding promise or performance on the other side (see *CONTRACT*). It was formerly held that the consideration must appear in the memorandum of writing, not necessarily in express terms, but at any rate as a matter of fact and reasonable inference. Thus a promise to pay for goods to be supplied to another was held to disclose a consideration, viz., the future supply of goods. But when the promise was to pay for goods already supplied, no consideration was disclosed. By the Mercantile Law Amendment Act (19 and 20 Vict c 97), passed in consequence of representations made by merchants in Scotland and the North of England, who found the difference between Scotch and English law as to written contracts a source of great inconvenience, this section of the Statute of Frauds was repealed. The Mercantile Law Amendment Act also declares that a guarantee given to or for a firm shall cease on any change taking place in the persons constituting the firm, unless a continuance of the promise is expressly stipulated or of necessity to be inferred. The corresponding Act for Scotland (19 and 20 Vict c 60) requires all guarantees, securities, or cautionary obligations, and all representations as to the character of any person made with the view of obtaining credit, money, &c., for such person to be in writing in order to be binding, and establishes the same rule as the English Act with reference to guarantees to or for a firm.

GUARATINGUETA, a town of Brazil, in the province of São Paulo, situated near the right bank of the Parahiba, about 40 miles N.E. of the city of São Paulo. It was founded in 1661 by the Captain M^{te} Diomene da Costa. The houses are almost all constructed of mud, and there are few buildings of any note except the churches, of which the chief is dedicated to St. Anthony. A considerable traffic is fostered by the fertile character of the surrounding district and the situation of Guaratingueta on the road between São Paulo and Rio de Janeiro. Population 7400. According to Spix and Martius the name of the

town is equivalent to "the place where the sun turns," and refers to its vicinity to the tropic of Capricorn. See Milhet de Saint-Adolphe, *Diccion Geogr do império do Brazil*, 1870.

GUARDI, FRANCESCO (1712-1789), a Venetian painter, was a pupil of Canaletto, and followed his style so closely that his pictures are very frequently attributed to his more celebrated master. Nevertheless, the diversity, when once perceived, is sufficiently marked.—Canaletto being moribund, solid, distinct, well-grounded, and on the whole the highest master, while Guardi is noticeable for a spurious touch, sparkling colour, and picturesque sketched figures—in these respects being fully equal to Canaletto. Guardi sometimes coloured Canaletto's designs. He had extraordinary facility, three or four days being enough for producing an entire work. The number of his performances is large in proportion to this facility, and to the love of gun which characterised our painter. Many of his works are to be found in England, seven in the Louvre, four, of exceptional merit, in the Mantua Palace, Venice.

GUARDIAN AND WARD. See *INFANT*.

GUARINTO, sometimes incorrectly named *Guarintio*, was the first Paduan painter who distinguished himself. The only date distinctly known in his career is 1566, when, having already acquired high renown in his native city, he was invited by the Venetian authorities to paint a *Pandure*, and some incidents of the war of Spoleto, in the great council-hall of Venice. These works were greatly admired at the time, but have long ago disappeared under repaintings. His works in Padua have suffered much. In the church of the Elemosini are allegories of the *Planets*, and, in its choir, some small sacred histories in dead colour, such as an *Eccle Homo*, also, on the upper wall, the life of St. Augustine, with some other subjects. A few fragments of other paintings by Guarinto are still extant in Padua. In the gallery of Bassano is a *Crucifixion*, carefully executed, and somewhat superior to a merely traditional method of handling, although on the whole Guarinto must rather be classed in that school of art which preceded Cimabue than as having advanced in his vestiges, likewise two other works in Bassano, ascribed to the same hand. The painter is buried in the church of S. Bernardino, Padua.

GUARINI, GIOVANNI BATTISTA (1537-1612), the author of the *Pastor Fido*, was born at Ferrara on the 10th of December 1537, just seven years before the birth of Tasso. He was descended from Guaimo of Verona (see next article). The young Battista studied both at Pisa and Padua, whence he was called, when not yet twenty, to profess moral philosophy in the schools of his native city. He inherited considerable wealth, and was already early in life to marry Taddea de' Boidelle, a lady of good birth. In 1567 he entered the service of Alphonso II., duke of Ferrara, thus beginning the court career which was destined to prove a constant source of disappointment and annoyance to him. Though he cultivated poetry for pleasure, Guarini aimed at state employment as the serious business of his life, and managed to be sent on various embassies and missions by his dual master. There was, however, at the end of the 16th century no opportunity for a man of energy and intellectual ability to distinguish himself in the petty sphere of Italian diplomacy. The time too had passed when the profession of a courtier, painted in such glowing terms by Castiglione, could confer either profit or honour. It is true that the court of Alphonso presented a brilliant spectacle to Europe, with Tasso for titular poet, and an attractive circle of accomplished ladies. But the two dukes of Ferrara were an illiberal pair, feeding his severity with promises, and ever ready to treat them with the brutality that condemned the author of the *Gerusalemme Liberata* to a madhouse. Guarini spent his time and money

to little purpose, suffered from the spite and ill-will of two successive seigniors,—Figna and Montecassini,—quarrelled with his old friend Tasso, and at the end of fourteen years of service found himself half-taunted, with a large family and no prospects. When Tasso was condemned to St. Anna, the duke promoted Guarini to the vacant post of court poet. There is an interesting letter extant from the latter to his friend Cornelio Bentivoglio, describing the efforts he made to fill this place appropriately. "I strove to transform myself into another person, and, like a player, reassumed the character, costume, and feelings of my youth. Advanced in manhood, I forced myself to look young, I turned my natural melancholy into artificial gaiety, affected loves I did not feel, exchanged wisdom for folly, and, in a word, passed from a philosopher into a poet." How ill-adapted he felt himself to this magnanimous life may be gathered from the following sentence: "I am already in my forty-fourth year, the father of eight children, two of whom are old enough to be my censors, while my daughters are of an age to marry." Abandoning so uncongenial a strain upon his faculties, Guarini retired in 1582 to his ancestral farm, the Villa Guarini, in the lovely country that lies between the Adige and Po, where he gave himself up to the cares of his family, the nursing of his dilapidated fortunes, and the composition of the *Pastor Fido*. He was not happy in his domestic lot, for he had lost his wife young, and quarrelled with his elder sons about the division of his estate. Litigation seems to have been an inevitable vice with Guarini; nor was he ever free from legal troubles. After studying his biography, the conclusion is forced upon our minds that he was originally a man of robust and virile intellect, ambitious of greatness, confident in his own powers, and well qualified for serious affairs, whose energies found no proper scope for their exercise. Literary work offered but a poor sphere for such a character, while the enforced inactivity of court life soured a naturally capacious and choleric temper. Of poetry he spoke with a certain tone of condemnation, professing to practise it only in his leisure moments, nor are his miscellaneous verses of a quality to secure for their author a very lasting reputation. It is therefore not a little remarkable that the fruit of his retirement—a disappointed courtier past the prime of early manhood—should have been a dramatic masterpiece worthy to be ranked with the classics of Italian literature. Deferring a further account of the *Pastor Fido* for the present, the remaining incidents of Guarini's restless life may be briefly told. In 1585 he was at Turin superintending the first public performance of his drama, whence Alphonsus recalled him to Ferrara, and gave him the office of secretary of state. This reconciliation between the poet and his patron did not last long. Guarini moved to Florence, then to Rome, and back again to Florence, where he established himself as the courtier of Ferdinand de' Medici. A dishonourable marriage, pressed upon his son Guarino by the grand duke, roused the natural resentment of Guarini, always scrupulous upon the point of honour. He abandoned the Medicæan court, and took refuge with Francesco Maria of Urbino, the last scion of the Montefeltro-della-Rovere house. Yet he found no satisfaction at Urbino. "The old court is a dead institution," he writes to a friend, "one may see a shadow of it, but not the substance in Italy of to-day. Ours is an age of appearances, and one goes about wounding all the eyes." This was true enough. Those dwindling, deadly lively little residence towns of Italian ducal families, whose day of glory was over, and who were waiting to be slowly absorbed by the capacious appetite of Austria, were no fit places for a man of energy and independence. Guarini finally took refuge in his native Ferrara, which, since the death of Alphonsus, had now devolved to the papal see. Here, and at the Villa Guarini, his last years were passed in study,

lawsuits, and polemical disputes with his contemporary critics, until 1612, when he died at Venice in his seventy-fifth year.

The *Pastor Fido* is a pastoral drama composed not without reminiscences of Tasso's *Amarilli*. The scene is laid in Arcadia, where Guarini supposes it to have been the custom to sacrifice a maiden yearly to Diana. But an oracle has declared that when two scions of divine lineage are united in marriage, and a faithful shepherd has atoned for the ancient error of a faithless woman, this inhuman rite shall cease. The plot turns upon the unexpected fulfilment of this prophecy, contrary to all the schemes which had been devised for bringing it to accomplishment, and in despite of apparent improbabilities of diverse kinds. It is extremely elaborate and, regarded as a piece of cunning mechanism, leaves nothing to be desired. Each motive has been carefully prepared, each situation amply developed. Yet, considered as a play, the *Pastor Fido* disappoints a reader trained in the school of Sophocles or Shakespeare. The action itself seems to take place off the stage, and only the results of action, stationary tableaux representing the movement of the drama, are put before us in the scenes. The art is lyrical, not merely in form but in spirit, and in adaptation to the requirements of music which demands stationary expressions of emotion for development. The characters have been well considered, and are exhibited with great truth and vividness, the cold and eager hunter Silvio contrasting with the tender and romantic Matillo, and Cora's meticulous airs enhancing the pure affection of Amantillo. Doinda presents another type of love so impulsive that it prevails over a maiden's sense of shame, while the courtier Caimo brings the corruption of towns into comparison with the innocence of the country. In Caimo the poet painted his own experience, and here his satire upon the court of Ferrara is none the less biting because it is gravely measured. In Cora he delineated a woman vitiated by the same town life, and a very hideous portrait has he drawn. Though a satirical element was thus introduced into the *Pastor Fido* in order to relieve its ideal picture of Arcadia, the whole play is but a study of contemporary feeling in Italian society. There is no true reality whatever in the drama. This correspondence with the spirit of the age secured its success during Guarini's lifetime, this made it so dangerously seductive that Cardinal Bellarmine told the poet he had done more harm to Christendom by his blandishments than Luther by his heresy. Without anywhere transgressing the limits of decency, the *Pastor Fido* is steeped in sensuousness, and the immodesty of its pictures is enhanced by rhetorical concealments more provocative than nudity. Moreover, the love described is effeminate and watery, fit less as passion than as lust enveloped in a veil of sentiment. We divine the coming age of *crusades* and *castles*. Of Guarini's style it would be difficult to speak in terms of too high praise. The thought and experience of a lifetime have been condensed in these five acts, and have found expression in language brilliant, classical, chiselled to perfection. Here and there the taste of the 17th century makes itself felt in frigid conceits and forced antitheses, nor does Guarini abstain from sententious maxims which reveal the moralist rather than the poet. Yet these are but minor blemishes in a master piece of diction, glittering and faultless like a polished bas-relief of hard Corinthian bronze. That a single pastoral should occupy so prominent a place in the history of literature seems astonishing, until we reflect that Italy, upon the close of the 16th century, expressed itself in the *Pastor Fido*, and that the influence of this drama was felt through all the art of Europe till the epoch of the Revolution. It is not a mere play. The sensual refinement proper to an age of social decadence found in it the most exact embodiment, and made it the code of gallantry for the next two centuries.

The best edition of the *Pavonis Fides* is that of Venice (Gotti), 1602. The most convenient is that of Baidis, Florence, 1866. For Guarin's miscellaneous *Bone*, the Ferrara edition, in 4 vols., 1787, may be consulted. His polemical writings, *Piccola Piana* and *Secundo*, and his more comely called *Idiosyncrasie*, were published at Venice, Florence, and Rome, between 1588 and 1614 (A. S.).

GUARINO, or GUARINUS (1370–1460), of Verona, one of the Italian restorers of classical learning, was born in 1370 at Verona, and studied Greek at Constantinople, where for five years he was the pupil of Manuel Chrysoloras. When he set out on his return to Italy he was the happy possessor of two cases of precious Greek MSS which he had been at great pains to collect, it is said that the loss of one of these by shipwreck caused him such distress that his hair turned grey in a single night. He employed himself as a teacher of Greek, first at Verona and afterwards in Venice and Florence, in 1436 he became, through the patronage of Lionel, marquis of Este, professor of Greek at Ferrara, and in 1438 and following years he acted as interpreter for the Greeks at the councils of Ferrara and Florence. He died at Ferrara 14th December 1460, aged ninety.

His principal works are translations of Sesto and of some of the *Laws* of Plutarch, a commentary of the Greek grammar of Chrysoloras, and a series of commentaries on Plautus, Juvenal, Martial, and on some of the writings of Aristotle and Cæcilius Scaevola, *Pica e Dierglusia di Gio: Guarino* (Brescia, 1805–6).

GUARINO, also known as VARNUS, and surnamed from his birthplace FAVORINUS, FAVORINUS, or CAMERUS (c. 1450–1537), lexicographer and scholar, was born at Favosina near Cambrino about 1450, studied Greek and Latin at Florence under Politian, and afterwards became for a time the pupil of Lascaris. Having entered the Benedictine order, he now gave himself with great zeal to Greek lexicography, and in 1498 published his *Thesaurus variorum nomenclatorum ad horti adoniam*, a collection of thirty-four grammatical facts in Greek. He for some time acted as tutor to Giovanni dei Medici (afterwards Leo X.), and also held the appointment of keeper of the Medicean library at Florence. In 1514 Leo appointed him bishop of Nocera. In 1517 he published a translation of the *Apophthegmata* of Joannes Stobæus, and in 1523 appeared his *Etymologicum Magnum*, sive *Thesaurus unius et linguae Græcæ ex multis variorum auctoribus collecta*, a compilation which has been frequently reprinted, and which has laid subsequent scholars under great though not always acknowledged obligations. Guarino died in 1537.

GUASFALLA, a town of Italy, in the province of Reggio, at the influx of the Crostolo into the Po, about 24 miles NE of Parma. It is the seat of a bishop, and possesses a cathedral, San Pietro, an extensive but ruined castle of the 16th century, eight churches, a civil hospital, a gymnasium, a public library (*La Biblioteca Muldotti*) with 18,000 vols., a school of music, and a theatre. A statue of Ferrante I. of Gonzaga, by Leone Leoni of Arezzo, adorns the market place. The inhabitants are largely engaged in the growing of rice, for which the marshy land around the town is specially adapted, and they also manufacture silk, flannel, and linen. In 1871 the population of the town proper was only 2800, but that of the commune was 10,618.

Guastalla, or, as the older forms of the name appear, Guastalla or Waistalla, was founded by the Lombards in the 7th century. It acquired some fame in the Middle Ages as the seat of the council held by Frederick II. in 1106. In 1507 it is said to have been deprived of its fortifications by Duke of Gonzaga, and they were not restored till 1686. Maria Visconti of Milan, to whom territory it belonged, saved the town and district to the rank of a countship, and bestowed it on Guido Torelli, the husband of his cousin. In 1599 the Torelli family was displaced by the Venetians (Ferdinand), and in 1641 the new occupant got Charles V. to make the countship immediately dependent on the empire. In 1621 it was made a duchy. The last duke of Guastalla of the Gonzaga family died in 1747, and thenceforth the Spaniards have in the previous years taken possession of the town in the name of Queen Elizabeth,

Maria Theresa made good her claim to the imperial fief. At the peace of Aix la Chapelle it was ceded to the duke of Parma, and its subsequent history is practically that of Parma and Piacenza. In 1788 it was incorporated in the French Conventual Republic, and in 1805 it bore the title of province to Napoleon's sister Pauline. Parma, Piacenza, and Guastalla were handed over by the peace of Vienna to Maria Louise, the wife of Napoleon, and on his death they passed to Charles Bonaparte. In 1848 Guastalla was united to Modena, and in 1859 along with Modena it was incorporated with Italy. The area of the duchy was about 126 square miles.

GUATEMALA, or more rarely GUATEMALA, was founded

merely a captain-generalship of Spanish America, which included the fifteen provinces of Chiapas, Sacatepéquez, Baccarat, Sonsonate, San Salvador, Vera Paz and Peten, Chiquimula, Honduras, Nicaragua, Costa Rica, Totonicapán, Quetzaltenango, Solola, Chimaltenango, and Sacatepéquez, — or, in other words, the whole of Central America and part of the present territory of Mexico. The name is now restricted to a small part of the area which constitutes an independent republic.

The republic of Guatemala is situated between 13° 42' and 18° N lat., and between 88° and 93° 5' W long. Conterminous on the N with Mexico and Yucatan, it is bounded towards the E and SE by Belize or British Honduras, the Gulf of Honduras, and the republics of Honduras and San Salvador, and towards the SW it is washed by the Pacific. The Yucatan frontier is only partially fixed, and though the Mexican frontier was nominally determined as early as 1772, the interpretation of the terms of the agreement is still open to much debate. Towards British Honduras the boundary is fixed by the treaty of April 30, 1868, according to which it runs up the main channel of the river Sanction to the Chinca a Dios Falls, thence in a right line to Garbutt's Falls on the river Belize, and thence again in a right line due north to the Mexican frontier. The area of Guatemala is estimated at from 40,000 to over 50,000 square miles, an accurate statement is impossible, not only on account of the dulcify of frontier, but from the fact that the surveys are very imperfect. All the maps of the country contain a great deal of hypothetical material, especially in the filling up of the geographical details.

Mountains. — A large proportion of Guatemala may be generally described as mountainous. The main or central chain, which is usually considered a continuation of the Andes, runs in a wavy line from south-east to north-west, keeping on the whole parallel with the Pacific coast at distances of 40 or 45 miles. Its mean elevation is about 7000 feet, but none of its summits attain to 14,000. Though it forms the main watershed of the country between the Pacific and the Atlantic versant or slope, it is pierced in one or two places by rivers. In the neighborhood of the capital it bears the name of Sierra de las Nubes, in the north-west it is known as the Sierra Madre, and it enters the Mexican (ex-Guatemalan) state of Chiapas as the mountains of Istatan. A range called the Sierra de Chama, which, however, changes its name frequently from place to place, strikes eastward from the Sierra Madre towards Belize, where it is known as the Cockcomb, another similar range, the Sierra de Santa Cruz, continues east to Cape Cochon between the Rio Dulce and the Sarstún, and a third, the Sierra de las Minas or in its eastern portion Sierra del Mico stretches between the Rio Dulce and the Rio Motagua. Between Honduras and Guatemala the frontier is formed by the Sierra de Copan. There are no real plateaus in Guatemala such as *gros* its character to the Mexican region, the so-called plateaus of Quetzaltenango, Patzún, Guatemala, &c., being merely broad valleys amid the mountains, but the general relief of the country is of the most varied description, the mountains

² The question is argued at length in *Boletín de la Sociedad de Geografía Mexicana*, 1876.

descending in all kinds of terraces and underfalls. The number of volcanic summits is very great. Bernoulli gives a list of 14 or 15, and Puledda makes the number no less than 31. The following are those that are decidedly active—Pacaya, in 14° 21' 30" N lat and 90° 41' 34" E long, on the southern shores of lake Amatitlan, with its cone on the southern slope, Volcan de Fuego, 12,821 feet in height, in 14° 27' 25" N lat and 90° 53' 30" E long, near Old Guatemala, Atitlan, 11,849 feet in height, in 14° 38' N lat and 91° 14' E long, Quetzaltenango, 9358 feet in height, in 14° 53' 30" N lat and 91° 53' 30" E long, and Tajumulco, in 17° 9' 08" N lat and 92° 6' 7" E long. The last was observed in eruption by Bernoulli on occasion of the great earthquake of 1803. Lake Quetzaltenango, which is surrounded by an extensive *malpais*, it furnishes great supplies of sulphur. More famous, however, than any of these is the Volcan de Agua, or Watul Volcano, so called because in 1541 it destroyed the city of Old Guatemala by a deluge of water. It is situated in 14° 38' 48" N lat and 90° 53' 30" E long. The statement of Humboldt that it rises above the snow-line is a mistake, for that would be a height of about 14,500 feet, whereas the actual height of the mountain, according to Poggenhoff's revision of Captain Hall's trigonometrical measurement, is only 13,108 feet. When Dr. Schaezer and Dr. Wagner ascended the mountain on August 4, 1854, they found no traces of snow or ice, and though three weeks later a thin coating of snow appeared on the outer slopes of the crater, it was gone again in four days. The source of the great flood of water was probably a crater lake.¹

Rivers.—Guatemala is richly watered. On the western side of the sierras the rivers are short, and the streams, while very numerous, are consequently small and rapid, but on the western side a number of the rivers attain a very considerable development. The Motagua, whose principal head stream is called the Rio Grande, has a course of about 250 miles, and is navigable to within 90 miles of the capital, which is situated on one of its tributaries the Rio de los Vacos. It forms a delta on the south of the Gulf of Honduras. Of similar importance is the Polochic, which is about 180 miles in length, and navigable about 20 miles above the river-port of Tecmán. Before reaching the Golfo Amatico it passes through the Izabal Lake and the Golfo Dulce. A vast number of streams, among which are the Chuto, the Guadalupe, the Rio de la Pasion, unite to form the Usumacinta, whose noble current passes along the Mexican frontier, and flowing on through Chiapas and Tabasco, falls into the bay of Campeche. The Chiapas falls into a similar course.

Lakes.—There are several extensive lakes in Guatemala. The Lake of Peten or Laguna de Flores, in the centre of the department of Peten, is an irregular basin about 27 miles long, with an extreme breadth of 13. In an island in the western portion stands Flores the capital of the department, well known to American antiquaries for the number of ancient idols which have been recovered from its soil. On the shore of the lake is the stalactite cave of Jobitmal, of great local celebrity, and in its depths, according to the popular legend, may still be discerned the stone image of a horse that belonged to Cortes. The Lake of Izabal, already mentioned as the terminus of the Polochic river, is about 86 miles long, and would be of considerable value as a harbour if the bar at the mouth of the Rio Dulce did not prevent the upward passage of seafaring vessels. As a contrast the Lake of Atitlan is a land-locked basin encompassed with lofty mountains and possessing no visible outlet for its waters, which are replenished by numerous streams. It is about 18 miles long, with a maximum

breadth of 9 or 10 miles, and it lies about 5300 feet above the sea level. "On its banks," says Mr. Boddan Vlietham, "stand eleven villages, whose situations are so varied that their climates and productions are those of the cold, the temperate, and the tropical regions, and whose inhabitants speak different dialects."² About 8 or 9 miles south of the capital lies the Lake of Amatitlan, with the town of the same name at its western extremity. It lies about 3980 feet above the sea, and has a length of 9 miles and a breadth of about 3. On the borders of San Salvador and Guatemala there is the lake of Guaya, about 20 miles long and 12 broad, at a height of 2100 feet above the sea. It is connected by the river Ostuma with the Lake of Ayauza which lies about 1000 feet higher at the foot of the Andes. The large lakes, according to Dollfus, are not of crater origin.

Geology and Mines.—The best and indeed the only elaborate account of the geology of the country is given by Dollfus and Montemaior, who were members of the great French expedition for the exploration of the Mexican region. According to these savants, who, however, confess that their studies are only provisional, the basis rock is the granite which, along with tachytes and porphyries of very various character, intermingled with and overlaid by dietically volcanic products, constitutes the great band of the Sierra Madre. From the main ridge towards the Atlantic there is a rich development of mica schist, and calcareous foundations of secondary origin, and probably Jurassic age, while the volcanic of the Pacific is almost covered with debris alluvium washed down along the rapid slopes. Mastodont and elephant remains have been discovered in the tuffs. The country as a whole may be said to owe its shape to the porphyries. Though some of the strata are essentially metaliferous, Guatemala possesses few mines of importance. During the Spanish rule about 40 million pesos of silver were obtained at Alotepeque in Chiquimula, and the works are still carried on, though with poorer results. Lead is found extensively in Huehuetenango and Yatepea, beds of excellent coal exist in Izabal, marble is quarried at San Juan in Guatemala, and on the Rio Honda in Zacapa, and lithographic stone is met with in the last-mentioned department.

Climate.—Except in the marshy lagoons along the Pacific, which are inhabited by groups of fishers and salt-gatherers, the climate of Guatemala is considered a healthy one. The peculiar relief of the country gives rise to a large amount of local differences in the matter of heat and cold, but the whole may be truly divided into a tropical or low-lying region, a temperate or middle region, and a cold or elevated region. The tropical region, or *tierra caliente*, extends from the level of the sea to an elevation of about 1300 feet, the temperate, or *tierra templada*, from 1300 to 4900 feet, and the cold, or *tierra fria*, from 4900 to 8200 feet. Fortunately for the future of Guatemala the templada is by far the most extensive. In the caliente the rainy season lasts four months. During that period the south west wind prevails, and is often tempestuous like the Cordonezo de San Francisco, or "flagellation of St. Francis," on the coast of Mexico, during the dry season the north wind is the most usual. The rainy season lengthens as we ascend to the templada. The Boca Costa district indeed has a rainy season of seven months, from May to November, and the dry season is not completely dry. Higher still, in the tierra fria, the rain lasts five months, from May to October, and the dry season is quite worthy of the name. At Guatemala, the only place where meteorological observations have been made through a long series of years, the minimum thermometer readings varied from 41° to 45° Fahr in the five years 1859 to 1863, and the maximum from 84° to 87°.

¹ See *Annuaire Central Americain*, 1877, p. 108.

¹ See Wagner, *Wissenschaftliche Reisen im tropischen Amerika*.

forces it was one of the richest and most beautiful cities of Spanish America, possessing about 100 churches and convents and more than 80,000 inhabitants. The ruins are still almost majestic, and many of the buildings appear as if they had been fortresses. Among those best preserved are the ancient residences of the Spanish governors, now occupied by the administration, and the university building, now the national college. Great damage was done to the place by the earthquake of September 1874. The population is about 20,000. An older Guatemala was situated at Ciudad Vieja or Almalong, but seventeen years after it was founded by Alvarado it was carried away by the great inundation to which the Volcan de Agua owes its name.

GUAYÁ (from the Mexican *guayaba*) is the name applied to the fruits of species of *Psidium*, a genus belonging to the natural order *Myrtaceae*. The species which produces the bulk of the guava fruits of commerce is *Psidium Guayana*, Radd., a small tree from 15 to 20 feet high, a native of the tropical parts of America and the West Indies. It bears short-stalked egg-shaped or oblong leaves, with strongly marked veins, and covered with a soft tomentum or down. The flowers are borne on axillary stalks, and the fruits vary very much in size, shape, and colour, numerous forms and varieties being known and cultivated. The variety whose fruits are most valued is that which is sometimes called the white guava (*P. Guayana*, var. *pyramicum*). The fruits are pear shaped, about the size of a hen's egg, covered with a thin bright yellow or whitish skin filled with soft pulp, and of a light yellowish tinge, and having a pleasant sweet-tart and somewhat aromatic flavour. *P. Guayana*, var. *pyramicum*, produces a more globular or apple-shaped fruit, sometimes called the red guava. The pulp of this variety is mostly of a darker colour than the former and not of so fine a flavour, therefore the first named is most esteemed for eating in a raw state, both, however, are used in the preparation of two kinds of preserve known as guava jelly and guava cheese, which are made in the West Indies, and imported thence to England, the fruits are of much too poisonous a nature to allow of their importation in their natural state. The two varieties here mentioned have been described by some botanists as distinct species. They have both been introduced into various parts of India, as well as in other countries of the East, where they have become perfectly naturalized. Though of course much too tender for outdoor planting in England, the guava thrives there in hot-houses or stoves.

Psidium Cattleianum, Sab., a tree of from 10 to 20 feet high, supposed to be a native of Brazil, but originally brought to Europe from China, is known as the purple guava. The fruit, which is very abundantly produced in the axils of the leaves, is large, spherical, of a fine deep claret colour, the rind is pitted, and the pulp is soft, fleshy, purplish, reddish near the skin, but becoming paler towards the middle, and in the centre almost or quite white. It has a very agreeable acid sweet flavour, which has been likened to that of a strawberry.

GUAYAYQUIL, or SANTIAGO DE GUAYAYQUIL, the principal seaport of the republic of Ecuador, South America, is situated on the western bank of the Guayaquil river, about 20 miles from its mouth, in 2° 13' 24" S lat and 79° 51' 24" W long. The site forms part of a low and level tract of ground bounded on the north by the hills of Santa Ana, and the streets are for the most part laid out with great regularity. To the north lies the old town, mainly inhabited by the poorer classes, to the south the new town. As the houses are generally built of wood or bamboo and mud, the risk of conflagrations is unusually great, and a strong fire-brigade is maintained. Since 1870 the town has been drained, the river has been dredged, and an

abundant supply of good water has been brought from a distance. The principal streets are lighted with gas. None of the public buildings are of any architectural interest. All the churches, with the exception of Santo Domingo, are built of wood. There are two colleges (San Vicente and San Ygnacio), a civil hospital (De la Caidada), a new and commodious military hospital, municipal buildings, and a custom-house.

As its harbour is one of the best on the Pacific coast, and permits vessels of large tonnage to come up to the town, Guayaquil is the centre of the foreign trade not only of Ecuador but of part of Peru, and has regular steamship communication both with America and European ports. Bimboes, cocoa, coffee, hides, india rubber, ivory nuts, acallilla, and Panama hats are the staple articles for the outgoing cargo, and there is a demand for pine-apples, sugarcane, and other fresh fruits for Chile and Peru. The average value of the exports in the five years from 1867 to 1871 was £420,785, and the value of the imports increased from £131,860 in 1867 to £1,168,656 in 1871. In 1874 there entered 79 British vessels, other 57 foreign vessels, and 20 national vessels, with a tonnage respectively of 118,660, 25,979, and 2222. One of the greatest hindrances to a development of the export trade is the want of proper facilities from the interior. It is only recently that the carriage road to Quito has been completed. Below the town there is a large station on ship-building yard of great repute on the Pacific coast. The Guayaquil bank, with a capital of £9,000,000 in stock and bonds, was founded in 1868, and the Banco de Crédito Hipotecario, with a capital of £400,000, from 1872. The population of the town is from 20,000 to 24,000, mainly mulattoes, mestizos, and Indians.

Santiago de Guayaquil was so called because it was founded on St. James's Day, 25th July 1521, 25th July 1524, or by the Viceroy, October 6, 1535, it was officially constituted the same year by Buldores, and two years later it was restored by Francisco Ornelas. In the course of the 17th and 18th centuries the municipality in its history are the attacks of pirates and disorders of law. The Dutchman Jacob Clerk was the assailant in 1621, the Frenchman David in 1686-7, William Dumouris in 1707, and (supposed) in 1709. As late as 1741 the only defence were three militiamen posted in the river, but in 1758 the town was made the seat of a governor, and a good castle and other fortifications were constructed. The following year a great fire destroyed property to the value of 2,000,000 pesos, and in 1837 Guayaquil was struck the second time by a ship.

See YLLIEMER, *Geographia del Ecuador*.

GUAYARA, LA, or LA GUAYARA, a town of Venezuela, in the province of Caracas, about 8 miles from the city of Caracas, in 10° 30' N lat and 71° 40' W long. It is situated on a low-lying strip of coast, but at the same time has a certain amount of picturesque scenery as seen against the background of the Cordilleras. Being one of the four principal ports (*puertos habilitados*) of the country, it enjoys a degree of commercial prosperity, but its trade, which is mainly in the hands of Germans, is almost exclusively of the transit description. Its imports are principally from Hamburg and Bremen. There is regular steamboat communication with Puerto Cabello, Manacabo, and St. Thomas. The population is about 4000. The railway to Caracas, though constructed for, has been stopped. The municipality maintains 19 schools, in which 370 boys and 260 girls are educated free of expense.

GUBBIO, a city of Italy, in the province of Umbria, about 20 miles N. of Perugia. Built along the western ledges of Monte Calvo, it shares alike in the grandeur of the mountains and the beauty of the plain, and its churches and palaces are brought into relief by the varying elevation of the site. Its ancient walls are still retained, and a certain mediæval impress lingers about the place. Besides the cathedral of SS. Mariano and Giacomo, which consists of a small single nave and has a fine wheel window, San Francesco may be mentioned for the sake of the Conception by P. Signorilli, S. Agostino for a Madonna del Soccorso by Giovanni Nelli, and S. Maria della Terra with the same artist's finest work, a votive fresco. Portions still remain of the old palace of the dukes of Urbino, built for Federico by Luciano Laurana. The palazzo municipale or del comune is a fine building erected between 1332 and 1346 after the designs of Matteo Giovannello, surnamed Gattapone.

seized the opportunity for his own advantage, in 1471 Adolphus was forced to set his father at liberty, and Arnold, in return for the service done him, made over his duchy to the Burgundian duke for 20,000 gulden, only reserving the usufruct till the close of his own life. On 23d February 1473 Arnold died, and Charles was duke of Guelderland. The town of Nimeguen made an heroic effort to oppose the Burgundian accession, but it fell after a lengthened siege. On Charles's death at the battle of Nancy in 1477, a party in the powerful city of Ghent became anxious to marry Charles of Egmont to their princess, Mary of Burgundy. Before the year was out, however (29th June 1477), the young man had perished before the walls of Tournay, against which he had led an army of Burgundians and Flemings to recover it from the French. By his marriage with the Princess Mary, Maximilian of Austria considered himself the rightful possessor of Guelderland, and he succeeded by 1483 in quelling all opposition. But ten years later young Charles of Egmont, the son of Adolphus, set foot once more in his native country, the people soon flocked to his standard, and victorious campaigns proved the capacity of the leader and the enthusiasm of the soldiers. The fierce contest continued for years, and Charles carried the war into the enemy's territories. In 1507 he pushed into Holland and Brabant, in 1512 appeared before Amsterdam, and in 1514 made capture of Groningen. It was not till 1539 that Charles V. granted him the lifelong occupation of Guelderland, Zutphen, Groningen, Coevorden, and Drenthe. In return he agreed that if he died childless his possessions should revert to the emperor, but such was his hatred of the house of Austria that towards the close of his life he planned to make France his heir. Thus, however, was prevented by the states of Guelderland mooting on his appointing as his successor William, the youthful son of the duke of Cleves and Juliers. Charles died 30th June 1538, and William assumed the title of duke. But Charles V. was not disposed to give up the rights secured by the treaty of Groningen, and after a contest in which much damage was done to various parts of the Low Countries, William was obliged to surrender his claims on 7th September 1543. On the rise of the Dutch republics most of Guelderland threw off the Spanish yoke. One "quarter" only, that of Roermond, continued subject, and it received the name of Spanish Guelderland, the other three "quarters," Nimeguen, Zutphen, and Arnhem, became Dutch Guelderland, and had their provincial diets twice a year. By the peace of Utrecht Spanish Guelderland or the Upper Quarter (Overkwartier) passed to Prussia, including the town of Guelders, but excluding Venloo, which went to the Netherlands, and Roermond, which went to Austria. By the peace of Paris (1814) the temporary divisions of the French revolutionary period were abolished, and all Guelderland was incorporated with Holland except the portion which still forms the Prussian circle of Düsseldorf.

GUELDERLAND, the modern province of the Netherlands, has an area of 1932 square miles, and its population in 1821, 1835, 1840, 1860, and 1873 was respectively 969,926, 923,167, 845,762, 401,864, and 437,778. The largest towns are Nimeguen (23,609 in 1876), Arnhem (38,017), Zutphen (14,513), Apeldoorn (18,851), Ede (10,982), and Rheden (10,636), and there are at least eighteen other communes with more than 5000 inhabitants.

See Pontanus, *Historia Geldi voc (Hindemijck, 1699)*, Van Spaen, *Historia van Gelderland* (Utrecht, 1814), Nijhoff, *Gelderland van de Gelders van de Graafschappen van Gelderland* (Arnhem, 1880, 8vo, 6 vols.), Nijhoff, *Het oorspronkelijk en de geschiedkundig van Gelderland* (Arnhem, 1889), J. C. Kemmer, *De Geschiedenis van Gelderland, van de Oorlog van de Graaf van Nassau, Gelre, Cleve, en Zutphen* (Arnhem, 1879), Baron Stolt, *Ons vaderland* (Groningen, 1879), *De Gelders*, v. H. Witkamp, *Land en Levenswijze van Nederland*, 1877.

GUELDER ROSE, so called from Guelderland, its supposed source, termed also Marsh Elder, Rose Elder, Water Elder (Germ., *Wasserhölzer*, *Schneeball*, Fr., *Vau-ne-Olier*, *l'Olivier d'Europe*), the *Viburnum Opulus* of Linnaeus, is a shrub or small tree of the natural order *Corniflorae*, and a native of Britain and other parts of Europe, and of Russian Asia. It is common in Ireland, but rare in Scotland. In height it is from 6 to 12 feet, and it thrives best in moist situations. The leaves are smooth, 2 to 3 inches broad, with 3 to 5 unequal serrate lobes, and glandular adnate stipules. In autumn the leaves change their normal bright green for a pink or crimson hue. The flowers, which appear in June and July, are small, white, and arranged in cymes 2 to 4 inches in diameter. The outer blossoms in the wild plant have an enlarged corolla, $\frac{1}{2}$ inch in diameter, and are devoid of stamens or pistils, in the common cultivated variety all the flowers are sterile, and the inflorescence is glomerul, hence the term "Snowball Tree" applied to the plant, the appearance of which at the time of flowering has been pictorially described by Cowper in his *Winter Walk at Noon*. The guelder rose bears juicy, red, elliptical berries, 4 lines in length, which ripen in September, and contain each a single compressed seed. In northern Europe these are eaten, and in Siberia, after fermentation with flour, they are distilled for spirit. The plant has, however, emetic, purgative, and narcotic properties, *Boissier (Hist. Voy., vol. i, p. 418, 2d ed., 1873)* has recorded an instance of the fatal poisoning of a child by the berries. Both they and the bark contain valerician acid. The woody shoots of the guelder rose are manufactured into various small articles in Sweden and Russia. See Loudon, *Arboretum*, vol. ii, 1838, and Syme, *Eng. Bot.*, v, p. 202, pl. 639.

GUELDERS, or GULDEN, a town of Rhineland Prussia, in the government district of Düsseldorf, chief and only town of the circle of Geldern, is situated on the Nieer, 28 miles NW of Düsseldorf. Its industries include the manufacture of cloth and hats, wool spinning, and wool, silk, and linen weaving. It has a Catholic and a Protestant church and two convents. The town was built in 1097, and was till 1343 the residence of the counts and dukes of Guelderland. It was fortified by Philip II, but its fortifications were razed by Frederick II. of Prussia in 1764. The population in 1875 was 5184.

GUELFS and Ghibellines. The names Guelfo and Ghibellino, as applied to parties in Italy, are Italianized forms of names which at an earlier period designated parties in Germany. Guelfo is the Italian form of Wolf, and Ghibellino the Italian form of Wabblingen, a castle of the emperor Conrad. In Germany these names, which are said to have been first used as battle-cries at the battle of Weinsberg in 1140, designated the struggle between the Wolf of Alboin and the imperial line of the Hohenstaufen. In Italy the names acquired a different meaning, being generally applied respectively to the party of the pope and the party of the emperor. The conflict between the authority of the emperor and the independence of the Italian towns began before the names were used in Germany. These parties first came into prominence in the Lombard league of 1167. In the war which followed we find the following distribution of parties on the Ghibelline side were Cicones, Pavini, Genoa, Tortona, Asti, Alba, Acqui, Turin, Ivrea, Ventimiglia, Savona, Albenga, Imola, Faenza, Ravenna, Forlì, Cesena, Rimini, the marquis of Montefiore, the counts of Lomello, Guastato, Bosio, &c., on the side of the Guelfs were Veronesi, Treviso, Padua, Vicenza, Verona, Brescia, Ferrara, Mantua, Bergamo, Lodi, Milan, Novara, Cremona, Alessandria, Piacenza, Parma, Reggio, Modena, Bologna. These names spread further in consequence of the literary rivalry which existed between several pairs of Italian towns, for instance, between Rome and Tusculum, Pisa and Genoa,

Ferrara and Mantua, Bergamo and Brescia. A further step in this direction was the division of the towns themselves into Guelph and Ghibellin parties. The struggle for the imperial throne between Philip of Swabia and Otto of Brunswick (1198-1208) enlisted the sympathies of Italy. The Guelph towns Milan, Piacenza, Brescia, Reggio, Modena, took the part of the Welf Otto. The 13th century witnessed a great increase of the jealousies between rival towns, and more serious divisions of the leading families in the towns themselves. Examples of this were the quarrels between the Montecchi and Capelleth at Verona, the Lambertazzi and Gherelmi at Bologna, the Rossi and Cologni at Parma, the Doria and Spinola, the Giamalati and Freschi at Genoa, the Bonadelloni and Amedei, the Donati and Uberti at Florence, the Colonna and Orsini at Rome, the Ragnucavalli and Polenta at Ravenna, the Della Torre and Visconti at Milan, the Cancellieri and Panciatichi at Pistoia, the Salimbeni and Tolomei at Siena.

Of the principal towns in North and Central Italy, *Azzo* was generally Ghibellin. Bergamo was torn in under by party quarrels. The Suardi fought against the Colonna, and afterwards both these against the Rivoli and Bonghi, it was generally more Guelph than Ghibellin. Bologna was generally Guelph. Brescia was much divided. It was generally Guelph, but was conquered by the Ghibellins in 1322. It came under the power of the Visconti of Milan in 1337. Cremona was generally Guelph, but occasionally Ghibellin. Always unhappy, it was wasted by the most violent party conflicts. The family of Cavalcabò led the Guelph party in this town in the 14th century. Ferrara was Ghibellin under the Torelli, it became Guelph under the Este. Florence, after 1158, was the chief support of the Guelphs. The struggles which desolated it were between different branches of the Guelph—the Bianchi, and Neri, and others. Forth was Guelph till 1315, afterwards Ghibellin under the Oldelfi. Genoa was divided between the two parties. Lucca was generally Ghibellin, but had hard work to maintain its position against the attacks of Florence. Mantua was Guelph up to 1220, afterwards mainly Ghibellin. Padua was the enemy of Venice. In 1227 it was Guelph, fighting against the Ghibellin Vicenza, about 1318 it became Ghibellin under the house of Carrara. Parma was divided in its sympathies. It was generally more Guelph than Ghibellin. Pavia was Ghibellin unless compelled to be otherwise. Perugia became Guelph in 1198. It was much torn by party quarrels. Piacenza was generally Guelph. Pisa was chiefly Ghibellin during a great part of its history. Pistoia was divided up to 1267, after which time it became mainly Guelph. Ravenna was chiefly Guelph under the family of Forlani. Rimini belonged to the family of Malatesta, which was divided between Guelph and Ghibellin. Siena was at first Ghibellin, in 1270 it became Guelph. Venice was seriously touched by these party quarrels. Verona was much divided. Up to 1259 it was mainly Guelph, under the Della Scala it was Ghibellin. Vicenza was Ghibellin after 1227, at a later period it followed the fortunes of Padua. Viterbo was Ghibellin after 1398.

It would be generally true to assert the principle that the Guelphs were more attached to liberty than the Ghibellins. The town of Alessandria was the creation of the Lombard league, a protest against the reduction of Italy under a German sovereign. Yet Dante, the keenest patriot, the most ardent aspirant towards the unity of Italy, was a Ghibellin. With him Ghibellinism meant (1) unity under a strong head, and (2) the abolition of the temporal power of the popes. No one, he thought, but an emperor could at firmly in the saddle or guide the reins of so fierce a steed. The best hope of obtaining this object lay in Henry VII of Luxembourg. But the object itself was probably impossible of realization. The death of Henry at Buonconvento

extinguished the last hope of uniting Italy under the supremacy of Caesar.

To give a full account of the party quarrels of Guelph and Ghibellin would be to write the history of medieval Italy. The names began to die out gradually at the beginning of the 15th century. Twenty years before the two parties had united in opposing John of Bohemia. The expedition of Charles IV into Italy destroyed what shreds still remained of respect for the authority of the empire, and with the extinction of Ghibellinism Guelphism perished also; yet we find the name of Guelph appearing in Milan in 1404, after the death of Gian Galeazzo Visconti, and also in 1447, in the struggle between Ludovico Sforza and the Duchess Bona of Savoy. In the conquest of Milan by Louis XII, in the beginning of the 16th century, we find the supporters of the emperor and Sforza called Ghibellins by Roman writers, and the French party called Guelph.

Of the literary supporters of either cause we can only mention a few. Bionnetto Latini, the master of Dante, was a Guelph. Dante himself, as we have seen above, was a Ghibellin, so was his friend Guido Cavalcanti. Petrarca was a Guelph, the three historians Villani are singularly impartial. For further information, see Wachsmuth, *Geschichte der Politischen Parteien*, vol. II. (o 3)

GUELPH, the chief town of Wellington county, Ontario, Canada, is situated in a fine agricultural district on an elevation on the river Speed, a branch of the Grand River, and on the Grand Trunk Railway and the Wellington, Grey, and Bruce division of the Great Western Railway, 45 miles west by south of Toronto. The river is navigable at this point, and there is a considerable shipping trade in wheat. Abundant water power is obtained for flour mills, saw-mills, and woolen mills, and there are also breweries, tanneries, and manufactures for agricultural instruments and sewing machines. The population in 1871 was 6818.

GUERCINO See BARBERI.

GUÉRET, a town of France, chief town of the department of Creuse, is situated on a mountain declivity near the Gouise, about 250 miles south from Paris. It has a church of the 18th century, a communal college, a normal school, two hospitals, a botanical garden, a library, a picture gallery, and a museum for natural history and antiquities. The principal industries are the manufacture of beer, leather, potash, combs, and buttons, and there is a considerable trade in wood and cattle. Guéret grew up in the 8th century round an abbey founded by Clotaire in 720. The population in 1876 was 4973.

GUERICKE, OTTO VON (1602-1686), an experimental philosopher, distinguished by his original discoveries of the properties of air, was born at Magdeburg, in Prussian Saxony, November 20, 1602. Having studied law at Leipzig, Helmstadt, and Jena, and mathematics, especially geometry and mechanics, at Leyden, he visited France and England, and, returning to Saxony, took up the profession of engineer-in-chief at Erfurt. In 1627 he was elected alderman of Magdeburg, and in 1646 mayor of that city, and a magistrate of Brandenburg. It was whilst holding these offices that Guericke devoted his leisure to scientific pursuits, especially in pneumatics. Incited by the discoveries of Galileo, Pascal, and Torricelli, he attempted the creation of a vacuum, a desideratum in science from before Aristotle. He began by experimenting with a pump on water placed in a barrel, but found that when the water was drawn off the air permeated the wood. He then took a globe of copper fitted with pump and stopcock, and discovered that he could pump out air as well as water. Thus Guericke became the inventor of the air-pump (1650). This important discovery was publicly explained before the emperor Ferdinand III at the imperial diet which assembled at Ratisbon in 1651. Guericke at the same time

illustrated in a simple but effective way the force of atmospheric pressure. Placing side by side two hollow horn spheres of copper, he exhausted the air from between them by means of pump and stopcock, and it is recorded that thirty horses, fifteen back to back, were unable to pull them asunder. The apparatus used on this occasion is still preserved in the imperial and royal library at Berlin. Guericke further demonstrated, by the aid of the air pump, that in a vacuum all bodies fall equally fast, that animals cannot exist therein, and other phenomena. He also invented the air-balance, and the anemoscope, a species of weathercock. The discovery of the property of electric repulsion is also attributed to him, and he made successful researches in astronomy, predicting the periodicity of the return of comets. In 1681 he gave up office, and retired to Hamburg, where he died May 11, 1686.

His principal observations are given in his work, *Experimenta nova, ut vocant, Magica quæ de vacuo spatio* (Amsterdam, 1672). He is also the author of a *Henrichs des Dänen unge und Zöcher ungs* (Müncheng. See Hoffmann, *Die von Guericke, Magdeburg, 1874*).

GUÉRIN, GEORGES MAURICE DE (1810-1839), a French poet, whose few compositions in prose and verse, published posthumously, show him to have possessed a true and rare genius, was descended from a noble but poor family, and was born at the château de La Cayla in Langueadoc, 4th August 1810. He was educated with a view to the church at a religious seminary at Toulouse, and then at the Collège Stanislas, Paris, after which he procured entrance to the society at La Chesnays in Brittany, founded by Lamennais, bishop of Rennes. Here his most intimate companions were persons whose tastes were literary rather than ecclesiastical, and his dreamy and meditative temperament found its solace and happiness more in intercourse with nature than in theological study or the exorcisms of piety. It was therefore only after great hesitation, and without being satisfied as to his religious vocation, that under the influence of Lamennais he joined the new religious order in August 1833, and when, in September of the same year, Lamennais, who had come under the displeasure of Rome, severed connexion with the society, Guérin's doubts as to his vocation returned in full force, and on the 7th October he renounced his novitiate. Early in the following year he went to Paris, where he obtained an engagement on the periodical press, but finding it impossible to submit to the mental drudgery of continuous literary work he became a teacher at the Collège Stanislas. In November 1838 he married a Creole lady of some fortune, but a few months afterwards he was attacked by a malady which proved to be consumption, and which terminated by death his short period of lustre and happiness, 19th July 1839. In the *Revue des Deux Mondes* for May 15, 1840, there appeared a notice of Guérin by George Sand, to which she added two fragments of his writings—one a composition in prose entitled the *Centaure*, and the other a short poem, *His Reliquæ*, including the *Centaure*, his journal, a number of his letters, and several poems edited by G. S. Trébutien, and accompanied with a biographical and critical notice by Sainte Beuve, appeared in 1840 in two volumes, and a translation of it was published at New York in 1867. Though Guérin was essentially a poet, his prose is more striking and original than his poetry. Its peculiar and unique charm arises from his strong and absorbing passion for nature, a passion whose intensity reached almost to adoration and worship, but in which the pagan was more prominent than the moral element. According to Sainte Beuve, "no French poet or painter has rendered so well the feeling for nature—the feeling not so much for details as for the ensemble and the divine universality, the feeling for the origin of things and the sovereign principle of life."

The name of *Eugénie de Guérin* (1806-1848), the

master of Maurice, cannot be omitted from any notice of him, if only on account of the ties of love that united them, but her *Journal*, published in 1861, English translation 1865, and her *Letters*, published in 1864, English translation 1865, indicated the possession of gifts of as rare an order as those of her brother, though of a somewhat different kind. In her case mysticism assumed a form more strictly religious, and she continued to mourn her brother's loss of his early Catholic faith. Five years older than he, she cherished a love for him which was blended with a somewhat motherly anxiety. In him she centred her chief earthly hopes, and after his death her only remaining purpose was to rescue his name from oblivion by the collection and publication of the scattered fragments of his writings. She died, however, on the 31st May 1848, before her task was completed.

See the notices by George Sand and Sainte-Beuve referred to above, *Sainte Beuve, Causeries du lundi*, vol. xii, and *Notices inédites*, vol. iii, G. Monet, *Causeries sur les familles de nos jours*, Paris, 1866; Schick, *L'Esprit des femmes de notre époque*, Paris, 1864; Maillé, *Études sur le de Guérin*, Berlin, 1864; Maillé, Paris, 1864; and E. de Guérin, *a monographie*, London, 1870, and Matthew Arnold's essay on Maurice and Eugénie de Guérin, in his *Essays in Criticism*.

GUÉRIN, JEAN BAPTISTE PAULIN (1783-1855), French painter, belongs to the group who specially identified the Restoration with art. Born at Toulon, 25th March 1783, of poor parents, he learnt, as a lad, his father's trade of a locksmith, whilst, at the same time, he followed the classes of the free school of art. Having sold some copies to a local amateur, Guérin started for Paris, where he came under the notice of Vincent, whose counsels were of material service. In 1810 Guérin made his first appearance at the Salon with some portraits, which had a certain success. In 1812 he exhibited Cain after the murder of Abel (formerly in Luxembourg), and, on the return of the Bourbons, was much employed in works of restoration and decoration at Versailles. His Dead Christ (Cathedral, Baltimore) obtained a medal in 1817, and this success was followed up by a long series of works, of which the following are the most noteworthy.—Christ on the knees of the Virgin, 1819; Anchises and Venus, 1822 (formerly in Luxembourg); Ulysses and Minerva, 1824 (Musée de Reims); the Holy Family, 1829 (Cathedral, Toulon); and Saint Catherine, 1838 (St Roch). In his treatment of subjects, Guérin attempted to realize those graces of conception, the liveliness of which was lost in the stilted effort to be correct. His chief successes were attained by portraiture, and those of Charles Nodder and the Abbé Lamennais became widely popular. Guérin died January 19, 1855. We possess no account of his life and works beyond that which is afforded by brief notices in contemporary biographical dictionaries.

GUÉRIN, FÉLIX NARCISSE (1774-1833), French painter, was born at Paris, May 13, 1774. The artistic ideal of the first empire found complete expression in his work, the most famous examples of which show a peculiar combination of the dry pseudo-classic style, then popular, with stage pathos of a highly exaggerated character, yet from his sterner went forth, as if in nameless protest against the defects of then master, the leaders of the Romantic and Realistic movements,—Delacroix and Géricault. The first teacher of Guérin was Nicolas Brunet, whom he left to place himself under Jean Baptiste Regnault, the representative, as contrasted with David, of a distinct form of the classic reaction modified by a tincture of Italian tradition. Guérin became the most distinguished of his pupils, and carried off one of the three "grands prix" offered in 1796, in consequence of the competition not having taken place since 1793. The pension was not indeed re-established, but Guérin fulfilled at Paris the conditions imposed upon a *pensionnaire*.

and produced various works, one of which brought him prominently before the public. This work, *Marcus Sextus* (Louvre), exhibited at the Salon of 1799, excited wild enthusiasm, partly due to the subject—a victim of Sulla's proscription returning to Rome to find his wife dead and his house in mourning—in which an allusion was found to the actual situation of the *émigrés*. Guérin on this occasion was publicly crowned by the president of the Institute, and before his departure for Rome (on the re-establishment of the École under Survé) a banquet was given to him by the most distinguished artists of Paris. In 1800, unable to remain in Rome on account of his health, he went to Naples, where he painted the Grave of Amyntas. In 1802 Guérin produced *Phædra* and *Hippolytus* (Louvre); in 1810, after his return to Paris, he again achieved a great success with *Andromache* and *Pyrrhus* (Louvre); and in the same year also exhibited *Cephalus* and *Aurora* (Collection Sommariva) and *Bonaparte* and the *Rebels* of Cairo (Versailles). The Restoration brought to Guérin fresh honours; he had received from the first consul in 1803 the cross of the legion of honour, and in 1815 Louis XVIII. named him Academician. The success of Guérin's *Hippolytus*, of *Andromache*, of *Phædra*, and of *Clytemnestra* (Louvre) had been ensured by the skillful selection of highly melodramatic situations, treated with the strained and pompous dignity proper to the art of the first empire; in *Æneas* relating to Dido the disasters of Troy (Louvre), which appeared side by side with *Clytemnestra* at the Salon of 1817, the influences of the Restoration is plainly to be traced. In this work Guérin sought to captivate the public by an appeal to those sensuous charms which he had previously rejected, and by the introduction of picturesque elements of interest which, even now, distract attention from the artificial mannerism too painfully apparent in his treatment of tragic subject. But with this work Guérin's public successes came to a close. He was, indeed, commissioned to paint for the Madeleine a scene from the history of St. Louis, but his health prevented him from accomplishing what he had begun, and in 1822 he accepted the post of director of the École de Rome, which in 1810 he had refused. On returning to Paris in 1828, Guérin, who had previously been made chevalier of the order of St. Michel, was enabled. He now attempted to complete *Pyrrhus* and *Phædra*, a work which he had begun at Rome, but in vain; his health had finally broken down, and in the hope of improvement he returned to Italy with Horace Yernet. Shortly after his arrival at Rome Baron Guérin died, on July 6, 1833, and was buried in the church of La Trinità de Monti by the side of Claude Lorraine. A careful analysis and criticism of his principal works will be found in Meyer's *Geschichte der Französischen Malerei*, but his life has not yet been made the subject of special treatment.

GUERNSEY, the second in size of the Channel Islands, is situated between 49° 25' and 49° 31' N. lat. and between 2° 30' and 2° 41' W. long., 80 miles W. of Normandy, and 51 miles S. of Portsmouth. The total area at low water is estimated at 15,560 acres, or rather more than 24 square miles, and of this about 10,000 acres are under cultivation. Gradually rising from the north to the south, the island attains its maximum elevation of 840 feet above mean tide at Hant Nez, above Point Fearth. According to J. A. Bird's "Geology of the Channel Islands" in *The Geological Magazine*, London, 1878, it consists geologically of three very unequal portions, one characterized by a very felspathic syenite and gneiss, another by a hornblende "granit," and a third by a micaceous syenite. The felspathic portion yields magnificent crystals of felspar, surpassing those of the porphyritic granites of Cornwall or Cumberland; and the hornblende portion occasionally affords crystals of black hornblende in similar perfection. No

Secondary or Tertiary rocks are found in position, but post-Tertiary clays containing flints are found all round the island and even on its summit, and Mr Bird is disposed to assign them to the interglacial period of submergence. The soil of Guernsey is generally a light sandy loam, and the subsoil consists for the most part of angular gravel, except in certain places occupied by a curious clay, chiefly composed of a silicate of alumina, which proves destructive to vegetable life. While the island does not grow sufficient grain for its own consumption, it has a large export of fruits and other garden produce. Parsnips were formerly one of the principal items, but they are now less extensively cultivated, having been supplanted by potatoes and turnips. Grapes, which were exported to the amount of 50 tons in 1873, are the source of an increasing trade. Granite is largely shipped at St Sampson.

For administrative purposes Guernsey is united with Alderney, Sark, Herm, and the adjacent islands in the bailiwick of Guernsey. The island proper is divided into the ten parishes of St Peter Port, St Sampson, Vale, Cithel, St Saviour, St Andrew, St Martin, Forest, St Peter du Bois, and Torteval. The administration is under the supervision of a Lieutenant-governor appointed by the crown; and the parliamentary assembly consists of a bailiff, twelve jurats, a procurer or attorney-general, the beneficed clergy, and twelve delegates elected by the people. Taxation is very light, and the annual revenue amounts to about £10,000. Ecclesiastically the island is a deanery of the Winchester diocese of the Church of England.

The only town of any great importance is St Peter Port on the eastern coast. In 1861 it had a population of 16,388 (6968 males and 9420 females), and in 1871, 16,166 (8731 males and 7435 females). The sea frontage of the town extends for about a mile, and is protected in nearly all its length by a wall with an esplanade. On the improvement of the harbour, which was begun in the 13th century by order of King Edward I., a sum of £288,000 has been expended since 1854. It is formed by two piers, which enclose an area of 73 acres, the southernmost of the two running out to Castle Cornet and then sending out a breakwater for about 3000 yards. The whole of the works are of the most massive description. Among the principal buildings of the town, which has been greatly improved by the formation of a new street from the harbour up to the hill, are the Government house, the court-house, Elizabeth college, the town hospital, St Stephen's church built in 1856, the Roman Catholic church, designed by Pugin, and the new vegetable market constructed at a cost of £6,000. On the higher ground above the town is a monument in memory of the Queen's visit to the island in 1846, and on the pier there was erected in 1863 a monument to the Prince Consort by Mr Durham, a copy of the monument in the gardens of the Horticultural Society at South Kensington. St Sampson, which is the only port besides St Peter Port, is situated at the eastern end of the Braye du Val, a depression which at no distant date used to form an arm of the sea at high tides, cutting the island into two unequal parts. The harbour accommodation has been improved at St Sampson contemporaneously with that of St Peter Port. To the south of the latter is the strong fort of St George's with barracks for 6000 men, and smaller forts, batteries, and martello towers are to be found on suitable points all round the coast.

By the old Guernsey laws, all the male population from sixteen to sixty are obliged to serve in the militia; but the custom of paying exemption fines has gradually become so common that the real force is very far below the nominal limit. Guernsey is both populous and wealthy, and the wealth is very evenly distributed among the people. In 1873 the assessment value of the town parish was

£3,564,750, or £2363 per head, and that of the rural parishes £1,531,630, £1233 per head. Like the neighbouring part of France, Guernsey still possesses numerous traces of its early inhabitants in the form of sepulchral caves, dolmens, and menhirs. The most remarkable group of the second class is in the north at Anctesme Details will be found in Mr Lukie's paper in vol 1 of the *Archæological Journal*, and in vols 1 and viii of the *Journal of the Archæological Association*, as well as in the special chapter in Dr Ansted's *Channel Islands*. The island is usually identified with the Sarnia of the latter Roman writers. Its present name would appear to be a corruption of the Norse for Green Isle. For details on its history see *CHANNEL ISLANDS*. An account of a number of its more eminent natives, many of whom have served with high distinction in the British army, will be found in *Sarnia*, or *brief Memoirs of many of her Sons*, Guernsey, 1862. Among the better known families are the Saumarezs, the Tuppers, and the Caroyas.

Besides the works referred to under *CHANNEL ISLANDS*, see *Documente d'histoire à l'île de Guernesey*, 1814; *Vues de Guernesey*, with descriptive letters, Edinburgh, 1867; John Jacob, *Annals of the Festivity of Guernsey*, London, 1880; Le Marchant, *Laws and Customs of Normandy as used in Royal Court of Guernsey*.

GUERRAZZI, FRANCESCO DOMENICO (1804-1873), Italian writer and politician, was born at Leghorn, August 12, 1804. He studied law at Pisa, and happened to become acquainted there with Byron, who produced a very strong impression on his lively imagination. Having taken his degree in law, he went back to Leghorn to practise his profession, but engaged at the same time in literary pursuits. In 1827 he published his first novel, *The Battle of Benevento*, a work displaying powerful imagination and strong patriotic feeling. While exiled in 1834 to Portoferraro, on the island of Elba, he wrote *Isabella Orsini* and *The Siege of Florence*, the latter producing great enthusiasm in Italy. The two compositions which followed, *Venosa Cibo* and *The New Tatyas*, are of inferior value. In 1844 Guerrazzi was again exiled to Portoferraro. When the revolution broke out in 1848, he was named deputy, then president of the council of ministers, and finally, in the beginning of 1849, along with Montanelli and Mazzini, temporary dictator of Tuscany. He had to expiate these few months of power by years of imprisonment and exile. He was banished first to Corsica, where he wrote *Beatrice Cenci*, *The Tower of Novara*, and *Fulcr*, and then to Genoa, where he composed the *Memento Homo*, *The Holo in the Wall*, *Messa Aiolto Marnardi*, *Paolo Pellicone*, *The Italian Plutarch*, *The Loves of Andrea Dorca*, *Francesco Ferruccio*, *Pasquale Paoli*, *The Sheeps of Rome*, and *The As* (*L'Asino*), a humorous work. When the kingdom of Italy was constituted, Guerrazzi was several times sent to parliament as deputy. Towards the end of his life he went to a villa he had on the sea-shore, near Genoa, not far from Leghorn, where his wife his novel entitled *The Dying Century*. He died there on the 25th September 1873, and was buried in the church of Montese, near Leghorn. His letters are being collected for publication under the direction of the poet Joseph Carducci.

See Guerrazzi's own *Apology*, Florence, 1861; Bono, *F. D. Guerrazzi and his Works*; De Guarente, *Ricordi biografici*, Florence, 1878; and Corbelli, *F. D. Guerrazzi*, Bells, 1878.

GUERRERO, formerly **TIZTALA**, the chief town of the state of Guerrero, Mexico, is situated on an elevation of about 5000 feet in a narrow and unhealthy valley in the Sierra Madre, 28 miles from the coast and 160 miles S.W. of Mexico. Mining is carried on, but not to any great extent, and coarse cloth is manufactured. The population in 1869 was 6501.

GUESOLIN See DU GUESCLIN.

QUEVARA, ANTONIO DE (c. 1490-1546), Spanish chronicler and moralist, was a native of the province of Alava, and passed some of his earlier years at the court of Queen Isabella. In 1528 he entered the Franciscan order, and he afterwards accompanied Charles V during his journeys and residences in Italy and in other parts of Europe. After having held successively the offices of count preacher, court historiographer, bishop of Guadix, and bishop of Mondoñedo, he died in 1546. His earliest work, entitled *Relos de príncipes*, o *Morales Amables*, published in 1529, and, according to its author, the fruit of eleven years' labour, is a kind of romance designed, after the manner of Xenophon's *Cyropædia*, to delineate in a somewhat ideal way for the benefit of modern sovereigns the life and character of an ancient prince distinguished for wisdom and virtue. It was very often republished in Spanish, and before the close of the century had also been translated into Latin, Italian, French, and English. It is difficult now to account for its extraordinary popularity,—its thought being neither just nor profound, while its style is stiff and affected. It gave rise to a literary controversy, however, of great bitterness and violence, the author having ventured without warrant to claim for it an historical character, appealing to an imaginary "manuscript in Florence." Other works of Quevara are the *Decada de los Casos*, or "Lives of the Ten Roman Emperors," in imitation of the *Historia* of Plutarch and Suetonius, and the *Epistolæ Familiaris*, sometimes called "The Golden Epistles," often printed in Spain, and translated into all the principal languages of Europe. They are in reality a collection of stiff and formal essays which have long ago fallen into merited oblivion (see Ticknor, *Hist. of Span. Lit.*, vol. ii.).

In Spanish literature occurs also the name of LUIS VELAZ DE GUEVARA (1570-1644), who is said to have written nearly 400 comedies, of which however only a few, and these of little value, have been preserved. This Quevara is chiefly noteworthy as having been the author of a prose romance entitled *El Duriño Coyote*, which suggested to Le Sage the ideas and materials of his *Duuple Botz*.

GUGLIELMI. There are several Italian musicians of this name, the most celebrated of them being PIERO, born at Massa Carrara in May 1737. He received his first musical education from his father, and afterwards studied under Durante at the Conservatorio di San Lioetto, Naples. His first operatic work was produced at Turin in 1755, and the success was such as falls to the lot of few primary efforts. Guglielmi's reputation was thenceforth established, and soon his fame spread beyond the limits of his own country, so that in 1762 he was called to Dresden to conduct the celebrated opera there. He remained for some years in Germany, where his works met with much success, but the greatest triumphs were reserved for him in England. He went to London in 1772, and stayed there five years, returning to Naples in 1777. He still continued to produce operas at an astounding rate, but was unable to compete successfully with the younger masters of the day. In 1793 he became maestro di cappella at St Peter's Cathedral, and died at Rome, November 19, 1804. He was a very prolific composer, and occupies a respectable if not absolutely first-rate position among the earlier masters of Italian comic opera. There is indeed in most of his scores a vein of humour and natural gaiety not surpassed by Cimarosa himself. In serious opera he was less successful. But here also he betrays at least the qualities of a competent musician. Considering the enormous number of his works, his unequal workmanship and the frequent instances of mechanical and slipshod writing in his music need not surprise us. The following are among the most celebrated of his operas:—*I due gemelli*, *La serva innamorata*, *La pastorella nobile*, *La*

bella pecatrice, Rinaldo, Ariassee, Dulone, and Enno e Lannia. He also wrote oratorios and miscellaneous pieces of orchestral and chamber music. Of his eight sons two at least acquired fame as musicians—Pietro Carlo (1763–1817), a successful imitator of his father's operatic style, and Giacomo, an excellent singer.

GUIANA, GUYAN^a, or GUAYAN^a, an extensive territory in the north eastern part of South America, comprehending in its widest acceptation all the extent of country lying between the rivers Amazon and Orinoco from 3° 30' S to 8° 40' N lat., and from 56° 22' to 68° 10' W long. It is bounded on the N by the Orinoco, on the Atlantic, E by the Atlantic, S by the rivers Negro and Amazon, and W by the Orinoco and the Casiquiare. Its greatest length from east to west is about 1200 miles, its greatest breadth, from the mouth of the Orinoco to the confluence of the Rio Negro with the Amazon, about 800 miles, and the estimated area is 600,000 square miles. This vast territory is divided into Brazilian (formerly Portuguese) Guiana, Venezuelan (formerly Spanish) Guiana, and Colonial Guiana. The first two divisions, comprising about five-sixths of the entire region, are claimed by or included in Brazil and Venezuela respectively, and stretching eastward from the mouth of the Orinoco towards that of the Amazon lie the territories of British, Dutch, and French Guiana, which are in that order noticed below.

Columbus in 1498 decided that the Orinoco must flow through some vast continent. Vincent Yanez Pinzon, a Spanish navigator, is believed to have first sailed up the Amazon from the coast. Vasco Nuñez landed on the coast of Guiana in 1504, but the discovery is also claimed for Diego de Odras, one of the captains of Cortez in the conquest of Mexico in 1531. Sir Walter Raleigh ascended the Orinoco in 1595 in search of the El Dorado. The first settlement is stated to be that of some Dutch people in 1680 near the river Pomeroon. This possession was contested by the Spaniards, but in 1618 a colony of Zealanders on the banks of the Essequibo was reported in a flourishing condition. English and subsequently French colonization was attempted up the Surinam river. The English returned in 1662 to Paramaribo, and in 1662 the whole colony was granted by Charles II. to Lord Willoughby. In 1669, however, Dutch Guiana covered all the territory now divided into British, Dutch, and French. In 1712 the French attacked the settlement and exacted a contribution. In 1732 Berbice received a constitution

from the states-general, and in 1763 there was a formal insurrection of negro slaves who had been imported from Africa. In 1781 Rodney took possession, and though the colonies were restored to Holland in 1783, they surrendered again to the British in 1796. The Dutch resumed authority in 1802, and in 1803 the proper history of British Guiana began.

BRITISH GUIANA, when finally acquired in 1803, and formally ceded in 1814, consisted of the three colonies, Demerara, Essequibo, and Berbice, so named after the principal rivers which drain them. These were consolidated into one colony in July 1831. It is bounded on the N and N E by the Atlantic, E by Dutch Guiana, from which it is separated by the river Corantyn, S by Brazil, and W by Venezuela. It has between 6° 40' and 8° 40' N lat., and 57° and 61° W long., and has an estimated area of 76,000 square miles, but the boundaries are still disputed by Venezuela and Brazil. An engagement, however, exists between the British and Venezuelan Governments that neither shall occupy territory claimed by both. The colony has now three divisions, called counties—Berbice, extending from the Corantyn about 95 miles along the sea-coast, Demerara from the Abarr about 65 miles, including Georgetown, the capital, and Essequibo, from the river of that name about 120 miles to the Bauma near the Orinoco mouth. There is thus a length of coast of 280 miles, with an extent inland varying from 300 to 450 miles.

Surface—From the coast line seaward the ocean deepens very gradually, and at low tide extensive mud-flats and sandbanks are left bare. Traced inland, this fluvo-marine deposit is found to rise to 10 or 12 feet above high-water mark, and to end at an older deposit of sand and clay beds, which forms an extensive undulating country, rising to not more than 150 feet above the sea, and stretching back to where the solid rock strata underlying it crop out. Upon the rich alluvial soil of the depressed coast-land, and for a few miles up the rivers, the sugar estates are situated. They are not only protected by dams from the sea, but, as in wet weather water rapidly accumulates in the savannahs behind, they are similarly defended on that side also. A narrow sand reef, some little distance farther inland, running parallel with the coast line, marks a previous sea limit, and still farther back a higher range of coarse white sand probably marks a yet earlier coast. The eastern portion of the colony from the sources of the Corantyn and Essequibo is a rough inclined plane, sloping down to the sea-level from a height of about 800 feet, the most elevated part being mountainous and rising to 2000 feet above the sea. This plain extends westward and northward, broken by ranges of mountains, its western portion constituting part of the extensive savannah which stretches eastward from Brazil. Two great parallel mountain systems cross the colony from west to east, the greater being that of the Pacaraima and Merumé mountains, and the lesser including the Canuca, Cumucuma, and Corantyn mountains, while the Sierra Amara, a densely wooded chain rising to 2800 feet, forms the southern boundary of Guiana and the watershed between the Essequibo and the tributaries of the Amazon. The Pacaraima mountains, a wide extent of rough country traversed by broad valleys, extend from about 4° to 5° 30' N lat., and rise to 3000 feet between the Potaro and Siparun rivers, and to 7500 feet at Roaima mountain, which rises, a perpendicular inaccessible wall of red sandstone, at the extreme western limits of the colony. The southern portion of Pacaraima shows rugged hills and valleys strewn with rocks, but to the north, where the sandstone assumes table-shaped forms, there are dense forests, and the scenery is of extraordinary grandeur. The Imataca range lies between the Chuyuni and Bauma

11° 15' N to 8° N lat. A sandstone formation can be traced from the northern Essequibo mountains on the west to the Corantyn on the east. Interbedded with these three great layers of greenstone. The surface of a very large portion of the colony is composed of gneiss, which is seen in large rounded bosses in the river beds. Schist of different kinds is associated with gneiss in many localities. Quartz-porphry and felsite occupy extensive areas over the surface of the granite and underlying the gneiss. A large proportion of the surface rock in the interior is granite. The white sand at the sandhills on the Demerara and elsewhere is very pure and well-adapted for glassmaking. Gold has been found about 40 miles up the Cuyuni river. Attempts to work it have met with small success, and have been complicated with questions of boundary.

Rivers.—The colony is traversed by numerous large rivers, the principal being the Essequibo, Corantyn, Mazaruni, Cuyuni, Berbice, and Demerara. The Corantyn forms the boundary between British and Dutch Guiana. It rises in 3° N lat., 100 miles eastward of the Essequibo, flows generally northward, and falls into the Atlantic by a broad estuary in 6° N lat., 57° W long. It is navigable for small vessels for 160 miles from its mouth, and is remarkable for its magnificent cataraacts. The Cuyuni, coming from Venezuela, runs a course of 120 miles through territory claimed as British. The Essequibo uses the Santa Anna, 0° 40' N lat., and after a course of at least 600 miles discharges itself into the ocean by an estuary 16 miles in width, in 7° N lat., 58° 40' W long. In this estuary are a group of islands where sugar is grown, several being from 12 to 15 miles long and 3 miles broad. The principal are Hog Island, Wakenam, and Leguan, a smaller one is named Tiger Island. The entrance of the Essequibo is difficult owing to deposits of mud and sand. Its course lies through forests of gigantic vegetation. About 43 miles from its mouth it is joined by the Mazaruni, which is itself joined by the Cuyuni at 8 miles from its mouth. The cataraact of which one of the greatest is the King William's Cataraact of Schomburgk, in 3° 14' 35" N lat., put a stop to the navigation of the Essequibo by large vessels about 50 miles up. In 3° 57' 30" N lat. and 58° 3' W long it receives the Rapununi, which has a course of 230 miles. Another large tributary is the Potaro, upon which is the celebrated Kaieteur (Old Man's) Fall, so named from an Indian legend, and discovered on April 24, 1870, by Mr. C. B. Brown of the Geological Survey, who, owing to cataraacts, took a fortnight to reach the fall from the coast up the Essequibo and Potaro. This fall, in 5° 8' N lat. and 59° 19' W long, is produced by the river flowing over a sandstone and conglomerate table-land 823 feet into a deep valley below. For the first 741 feet the water falls perpendicular, as one great continuous whitish column, circled by rainbows, into a basin below, continuing thence over a sloping cataraact 88 feet in height, and through the interstices of great blocks of rock, to the river-bed below. The head of the fall is 1180 feet above the sea. The river 200 yards above the fall is 400 feet wide, and the width of the fall itself varies, according to the season, from 240 to 370 feet. The Demerara or Demerary uses probably near 5° N lat., and after a northward course nearly parallel with the Essequibo for more than 200 miles, enters the Atlantic near 8° 50' N lat. and 58° 20' W long. It is navigable for 85 miles, and at its mouth at Georgetown is 1½ miles across. A bar, or deposit of mud and sand, prevents the entrance of large vessels at low tide. Farther east is the Berbice, whose source is probably about 3° 40' N lat. It is 2½ miles wide at its mouth in 5° 21' N lat., 57° 19' W long, and is navigable for 175 miles by vessels drawing 7 feet of water. The Canje creek falls into the Berbice near its mouth. Several large streams called creeks fall

directly into the Atlantic between the Berbice and the Demerara. The Boesant creek divides the counties of Demerara and Essequibo, and between the Essequibo and the Barima are the rivers or creeks Pomeroon, Moutuca, and Waini.

Climate.—The climate, especially in the interior, is healthy. The even temperature is considered suitable for pulmonary complaints, and tubercular consumption is unknown. There are no hurricanes, and gales are not frequent. Occasionally there is a long drought, but the following order of seasons is generally maintained. From the middle of April to June there is a long season of heavy rains, which decrease in July, the long dry season lasts from August to November, December and January comprise the short rainy season, and February and March the short dry season. The winds during the rains are generally westerly. In the dry seasons they blow from the ocean and modify the heat. The thermometer seldom rises above 90° or falls below 75° Fahr. At Georgetown the mean annual temperature is 81° 2'. The rainfall in 1878 was 60.97 inches, the average having been 74 inches for 1873-77.

Population.—The census of 1871 was as follows:—113,570 born in British Guiana (including 70,000 to 80,000 negroes, 10,000 born of Indian and Chinese parents, and the "coloured" population), 43,681 immigrants from Java, 6,505 Chinese, 7,025 from Madeira and Arroyos, 13,356 negroes from West Indian Islands, and 9,635 Europeans and others, total 193,491, exclusive of aborigines, estimated at 7,000. The estimated total population on 31st December 1876 was 225,365, and further explorations have increased the estimated number of aboriginal Indians. The aborigines are remnants of Indian tribes, such as the Arawaks, Waiwaks, Caribs, and many others, scattered in the interior of the country. They maintain themselves by fishing and hunting. "Traces of 'Indian picture-writing,' or 'carved figures,' have been found in some granite blocks up the Essequibo. On December 31, 1877, 22,000 East Indian immigrants were working under a five years' indenture on the estates, and 26,000 not under indenture. Since 1857, 10,815 East Indian coolies (including women and children), with savings amounting to £260,479, have availed themselves of their right to return passage. A number re-emigrate to the colony. The Indian Government supervises the emigration. In the colony an immigration department regulates labour, wages, and general treatment. About 5,000 are now annually introduced. Chinese have also been introduced with and without indenture.

Vegetation.—The vegetation is most luxuriant. The interior abounds in exhaustless supply of valuable timber, such as the mora and greenheart, largely used for shipbuilding. The climate induces a continuous succession of tropical fruit and nuts. Many of the trees yield gums, kauris, oils, and juices of more or less value, among which may be mentioned caoutchouc, and a gum called "balata," with properties intermediate between those of caoutchouc and gutta serena. The bark of the cash tree is used for tanning. The silk cotton tree, which grows 100 feet high and 12 feet round, yields a light grey silky cotton wool for stuffing pillows. Among the palm trees are the picturesque mountain cabbage palm, growing to the height of 100 feet, the cocoanut palm, the large tall tree palm, much esteemed for its beauty and fruit, and the cockatoo palm, which produces the most delicate cabbage of all the palm species. The papaya tree, 15 to 20 feet high, yields the sea coast. The tobacco plant grows wild, and indigenous cottons are numerous. A little rice is grown. The fruit of the plantain and banana is largely used for food, and the stems furnish fibre for paper making. Orice, lime, guavas, and pine apple are among the fruits of the country, and other productions are valuable for food or medicine. Indigo used to be cultivated. Amelita, from which the well known dye is obtained, is indigenous, and logwood and vanilla are also found. Maize, cassava, yams, papaw tree fruit, sweet potatoes, peppers, and other productions are valuable for food or medicine. The largest of the water lilies, the *Victoria regina*, was first discovered in Guiana.

Animals.—Among the wild animals are the tapir or bush cow, the manatee (the flesh of which is sometimes eaten), the jaguar or "tigu," three kinds of art bear, the sloth, opossum, armadillo,

acouri (or hare), numerous monkeys, and vampires, measuring 30 inches from point to point of extended wing. The cayman, alligator, or crocodile of South America, 15 to 20 feet long, abounds in the rivers and on the coast, and other reptiles, and the iguana (the flesh of which is said to be suitable for eating), many lizards, and snakes (some venomous). Tortoises and turtles are common on the banks of the streams and in sandy districts of the coast. The bird, insect, and fish life is highly and wonderfully rich and varied.

Produce, Industries, and Commerce.—There are 120 sugar and 12 small coffee estates in the colony. Cotton was formerly exported, but the cultivation has now ceased. Coffee, the export of which in 1850 was 9½ millions of lbs., is now produced for the foreign market. The deep rich soil has induced large investments in the formation of sugar estates; but the industry has undergone great fluctuations. Exports in 1850, when negro apprenticeship terminated, fell from an average of 64,000 to 38,400 hds. The equalization of the English duties on free and slave-grown sugar still further restricted cultivation, exports in 1849 being only 22,000 hds. In 1854 matters had begun to mend. The prospect of obtaining cocoa lumberers from India and China causes new capital to be introduced and fresh energy employed. Cultivation was improved and extended, vacuum pans came to be more used, steam ploughs and tile-draining were successfully introduced. The value of melliculture improved from 1857 to 1876 was 2550,000. A quantity of 2 to 3 hds. (of about 17 cwt.) per acre is often obtained, but the average is 30 cwt. The juice expressed by the powerful rollers is about 60 per cent. of the weight of canes. The "Demarara crystals" are very popular for their purity and saccharine strength, and command high prices. The sugar exports in 1876 were 119,891 hds., fully equal to 106,000 tons; in 1877, 111,156 hds.; and in 1878 (a year with prolonged drought), 86,074 hds., a quantity worth to the colony £2,000,000. United Kingdom, but 20,000 and 32,000 hds. sent to the United States in 1876 and 1877 respectively. The rum exported in 1876 was 36,000 puncheons; in 1877 it was 32,581, and in 1878 28,752. The quantities of rum (some for consumption in the colony) in 1876 was 350,392 gallons. The export of molasses (of which less is made as the quality of the sugar improves) is principally to the United States and British provinces, the quantity being 14,320, 19,605, and 17,084 casks in 1876, 1877, and 1878. The same year timber exports (nearly all to the United Kingdom) were 404,436, 367,430, and 303,093 cubic feet. The woodcutting industry, under Government licences, is a considerable one, as is shown by the export of about 5 million shaves annually, and of 100,000 and 150,000 casks of charcoal-burning is carried on; 32,206, 35,631, and 47,740 barrels of charcoal were exported in 1876, 1877, 1878. There are 1,250,000 coconuts exported yearly. In 1853 the total value of imports was £247,183; in 1877, £2,229,908 (£1,070,898 from the United Kingdom); in 1878, £2,150,714. The exports were in 1853, £1,014,844; in 1877, £2,049,157 (£1,964,760 to the United Kingdom); and in 1878, £2,507,671. The value of exports and outwards was 234,085 tons in 1853, and 519,988 tons in 1877.

Government.—The government is vested in a governor appointed by the British crown and a court of policy, originally instituted by the Dutch in 1773 for Demerara, and including Essequibo in 1789. Berbice had until 1831 a separate constitution. The unofficial members of the court were elected by a college of kizers or electors, who were themselves elected by duly qualified inhabitants. In 1795 this college consisted of 120 members, and was reduced to 40 by the court of policy in financial matters. This resulted in an independent body, called financial representatives, being elected by the inhabitants who were qualified to vote for kizers. The financial representatives met the court in a separate session, called a session as the "combined court," to discuss finance and pass the annual tax ordinances. The civil list is not permanent, being renewed every seven years. All other ordinances or local laws are passed by the court of policy, and are subject to the royal confirmation by the queen. The colony is divided into five electoral districts, with a total of 838 registered electors. These districts elect for life one or two kizers, seven in all, and one or two financial representatives. The court is composed of the court of policy the seven kizers nominate two persons, one of whom is selected by the court. There are five unofficial members chosen as above, and five official members, viz., the governor, attorney-general, government secretary, auditor-general, and immigration agent-general. The public revenue in 1853 was £250,017, and the expenditure £238,687. In 1877 the revenue was £289,872, and in 1878 £408,003. Half of this revenue is derived from import duties, and the remainder principally from wine and excise duties, rum duty, and retail spirit duties. The expenditure in 1877 was £380,596, and in 1878 £417,996. The public debt in 1877 was £238,668. Public and mercantile accounts are kept in dollars (4s. 2d. sterling) and cents.

The Roman Dutch law is in force in civil cases, modified by orders in council and local ordinances; the criminal law is based on that of Great Britain, administered in the same way, except that there is no grand jury. The supreme court consists of the chief justice and two puisne judges. Appeal in cases involving

£500 and upwards lies to the privy council. There are an inferior court of civil justice, courts of admiralty and vice-admiralty, of petty debt (conducted by stipendiary magistrates), of bail and review (of magistrates' decisions). One judge sits in the supreme criminal court, and there is an inferior criminal court. Questions of law are decided by three judges in the court of crown cases reserved. Besides a police magistrate for Georgetown, there are thirteen districts, each with a stipendiary magistrate appointed by the secretary of state.

Towns.—For a notice of Georgetown, the capital (million population about 40,000), see vol. x. p. 480. The light-house, with revolving light visible for many miles, is at the north end, near the mouth of the river. The lightship is 12 miles in 6° 50' N. lat. and 53° 18' W. long. The chief town of Berbice is New Amsterdam, on the east bank of the Berbice river. It is well laid out, and has a population of 6000. The Berbice lightship is in 6° 20' 10" N. lat. and 57° 29' 40" W. long.

Religion and Education.—The diocese of Guiana was established in 1842. The official list shows—1 bishop, 1 archdeacon, 10 rectors, 14 curates, 2 incumbents, and several missionary clergymen and chaplains to institutions. The Church of England has 58 churches or chapels. The Coolie Mission Association and Diocesan Society maintain missionaries and catechists. The Church of England claims 90,000 members. The Church of Scotland has 10 ministers. The Roman Catholics also have several churches and mission stations. The Church of England receives an annual grant of £10,000 from the public revenue, the bishop's salary (£2000) being paid from imperial funds; the Church of Scotland has £5000, and the Roman Catholic Church £2500 from public revenue. There are also 14 Wesleyan Methodist ministers, a Moravian mission, and several chapels of Congregational Dissenters and others belonging to the London Missionary Society. The system of education is supervised by the general revenue commissioners. There are 4 schools maintained by the board of education. The estimate for primary education in 1878 was £25,065. The Church of England has 81 schools, of which 20 are those of those on whose estates the schools are situated.

Sawkins, in *Geology of British Guiana*, *Quarterly Journal of Geology Soc.*, London, 1871; Brown's *Census and Camp Life in British Guiana*, 1876; Britton's *Indian Tribes of Guiana*, 1870; *Colonial Office List*; *British Guiana Directory*; Bennett's *British Guiana*; *Journal of the Royal Geographical Society*, 1877.

II. DUTCH GUIANA, or SURINAM, lies to the E. of British Guiana, from which it is separated by the Corantijn or Corantyn in 67° 8' W. long. Its coast extends for upwards of 320 miles to the mouth of the Maroni or Marowijne, which forms the boundary towards French Guiana. The Dutch claim possession of 58,530 square miles; but of this extensive area, equal to more than four times that of Holland, not more than 3280, according to Wolbers, had been explored in 1868, the colonial territory did not comprise more than 640 square miles, and the actual area under cultivation was little over 200. In 1870 this last was 29,862 acres (47 square miles), and in 1876, 22,180. The principal settlements have been made in the lower valley of the Surinam, or between that river and the Suramanna on the W. and the Commewijne on the E. At its mouth the Surinam is 3 miles broad, and at Paramaribo, the capital, about half a mile. Ships of from 18 to 19 feet of draught can reach the anchorage in front of the town, which has room for 100 vessels. The water is of a dirty yellow colour with brown bubbles on its surface, and its current can be traced far out at sea. As yet no one has seen the source of the Surinam, but it is understood to be high up in the Tumac Humac hills. The principal tributaries are the navigable Para on the left hand and the Fausius Creek on the right, both of which join it about 6 or 7 miles above Paramaribo. The Marowijne or Maroni is a much larger river than the Surinam. Its water is clear as crystal, so that stones can be distinguished at a depth of 12 feet. Unfortunately its mouth, though about 4 miles broad, is full of sand-banks, and consequently it has been less visited than might have been expected from the excellent character of the country through which it flows. The banks are high

* An interesting account of a voyage up the Surinam, by Zimmerman, with a good map on a large scale, will be found in *Tijdschrift van het Nederlandsche Genootschap*, 1877.

enough to confine the floods, though at Aismna, about 45 miles inland, the difference of level between the dry and the rainy season is 23 feet. Between the rivers of Dutch Guiana there are remarkable cross channels available during the floods at least. The Maroni is even connected with the Comantyn on the one hand (though there is 200 miles of country between) and with the Oyapock on the other. As it communicates with the Cottica, which is in turn a tributary of the Commeweyne, a boat can pass from the Maroni to Paramaribo, thence by the Sommedelyk canal it can reach the Saranamaca, and from the Saranamaca it can proceed up the Coppename, and by means of the Nickerie find its way to the Comantyn.

Climate.—The climate of Surinam has long enjoyed a reputation for exception to unhealthiness which it does not appear to deserve. Though hot and moist like a Turkish bath, it seems congenial even to the European constitution. The mean temperature of the year is 80° 4° Fahr, that of the coldest month 78° and that of the warmest 96°. On the average of the eight years from 1847 to 1854 the rainfall at Monbyou is 129 inches, at Paramaribo 101, at Oldeland 108, at Groningen 91, and at Nickorio 87. According to the tables at the end of the *Jaarboek der Kon. Nederlandsche Meteor. Inst.* (Utrecht), the greatest quantity falls in May, June, July, September, and December. There are no endemic diseases, and though cholera, fever, and small-pox have appeared from time to time, they are not more violent than in more temperate regions. Leprosy and elephantiasis, introduced it is believed from Barbadoes, are not infrequent among the negro population. The former is locally known as *bonnia*. In 1790 there were only 7 patients in the lazaretto of Voorzorg, but by 1797 they had increased to 300, and in 1812 to 500. A new establishment was founded at Batavia on the right bank of the Coppename in 1823. Between 1831 and 1839 an average of 103 suspected persons were examined yearly, and 46 declared infected. In 1853 there were 418 inhabitants (216 males and 232 females) in the settlement, of these however 112 were personally free from the disease, though born and brought up among the patients.

Population.—Between 1838 and 1853 the free population of Surinam increased from 8993 (4242 males and 4651 females) to 13,193 (6700 males and 6484 females). In 1855 the total number of slaves was 31,780, of whom 27,914 (13,556 males and 14,358 females) were on the plantations and 3866 (2027 males and 1839 females) in private service. Since the abolition in 1863 many attempts have been made to augment the working population of the colony. Up till 1874 the total number of immigrants was 9049, of whom at least 2038 died. In 1870 a convention was signed between Holland and England for the regulation of the coolie trade, and a Dutch Government agent for Surinam was appointed at Calcutta. In 1873 2448 immigrants arrived from British India, and 1405 in 1874, but owing to dissatisfaction on the part of England with the Dutch arrangements there were none in 1875 and 1876. In December 1875 the whole population was stated at 51,329 (26,074 males and 25,255 females), exclusive of about 17,000 bush negroes and an uncertain number of Indians. There were 706 Europeans besides the soldiers and seamen in garrison and harbour, and the immigrants amounted to 4007 (2834 males and 1173 females), and comprised 2959 from British India, 698 from the West Indies, 352 Chinese from China, and 67 from the Dutch Indies and 25 soldiers from the Netherlands.

The bush negroes (bush negro) are the descendants of runaway slaves. They consist of three tribes—the Aukamans, the Saranamaccas, and the Bekon or Moesangs. The first, who number from 3000 to 4000, have their chief settlements in the district near the junction of the Lava

and the Tapanahoni with the Upper Maroway, but they are also settled on the Sara Creek, on the Upper Cottica, and on the Comutoito. The Saranamaccas, who are numerically about as important, dwell between the Saranamaca and the Upper Surinam. The bush negroes retain curious traces of their former connexion with Christianity, though they are and consider themselves pagans. Their chief god is Giau Gado (grand god), his wife is Maina, and his son Josi Keti. Various minor deities are also worshipped, Ampaka the bush-god, Toni the water god, &c. Among themselves they speak a language based on a bastard English, mingled with many Dutch, Portuguese, and native elements. The Maravian missionaries have promoted its cultivation, but it is almost certain to give way before the Dutch.

Vegetation.—A large portion of Dutch Guiana is covered with primary forests, but inferior to the lack of labour and cost of transport have prevented the utilization of this vast supply of timber and colonial wood. In some years, indeed the export of these materials is virtually exceeded by the import. An idea of the wealth that awaits the future prospector may be obtained from Poock's paper in the *West India* for 1854, where a list is given of 77 different kinds. Among the more important are the bolibol (*Lucuma neesmaniana*), known in the Nickerie mills as paribolibolch or horse flesh, the buimant (*Conioperium americanum*, Aubl.), the bulik (*Leptocarpus olivaceus*), which is much attacked by worms, the goelint (*Acacia robusta*, Schumbr.), the mulo and fende (lignum vitae), the pampulint (*Coprosma bicolorata*, L.), the kukan tree (*Bombax toleda*), the locust or coumbou, which is good both for timber work and fumigation, and the kopie (*Cordia alliodora*), largely used for burning. Besides these, which will be mentioned for a large part of his existence, nut, sago, and Curacao maize, yams, *kyrica* (*Arum esculentum*), arrowroot, okra or gombo, the ground nut or manna (*Arachis hypogaea*), Spanish pepper, the anna (*Solanum mammosum*), the bulbous, the *Carak* (*Enona muricata*), the panna de Cythre (*Spodopis cythraea*), and the *Mimosa americana* may be mentioned from the vast list of plants of interest for their useful qualities.

Culture.—The great staple of Surinam industry was formerly sugar. Between 1849 and 1868 the average quantity exported was 802,537 cwt., in 1869, two years after the commencement of the slaves, it sank as low as 151,312 cwt., and in 1870 it again reached the average between 1850 and 1871, viz. 212,000 cwt. In 1876 the production was 218,115 cwt., and the export 198,274 cwt. The first cocoa from Surinam was sent to Amsterdam in 1758, but it is only since about 1857 or 1860 that it has risen into favour with the colonists. In 1876 the production was no less than 262,007 cwt., and the export 26,002 cwt. Cotton and rice are next in order, the former having a yield in 1870 of 3800 cwt. and the latter of 215 cwt. The total exports of the colony had a value of 7,782,569 guilders of florins, of which Great Britain took 969,945, the United States 872,277, and the Netherlands 606,001. Of the total imports, valued at 8,154,222 guilders, the United States furnished the value of 1,224,000.

Mineral.—The gold diggings of Surinam are beginning to attract attention, the commission of 1874 having found 3 such authentic districts about the Maroway. By May 1876, 619,000 cwt. of metal had been rented to private persons, and a fair amount of success has attended the labours. The lead, silver, and iron ores may yet prove of importance.

Administration.—In 1805 several changes were introduced into the government of Surinam. The Colo Suriname was abolished, subject to modification from time to time by orders in council. A house of assembly was constituted, the members of which were never to be less than nine nor more than thirteen, four being appointed by the Government and the others by the electors. The franchise was given to all citizens paying 40 guilders of taxes. Elected members serve for six years. The ordinance of the governor in council became law only if passed in the assembly and sanctioned by the king, but a royal decree may override the strongest opposition of the assembly, and not infrequently the national assembly of the Netherlands disallows what has been inserted in the budget by the colonial assemblies. Besides the supreme

¹ Seventeen publications are mentioned by Willhelmslag in his *Surinamische Nieuwe Encyclopedische Winkler* (Amsterdam, 1854). For a review see *Nieuw Amsterd.* (Voortbinder), (Leyden), 1870, and Willhelmslag's *Dutch-Naga English-Nederlandsche Woordenboek* (Lobus, 1860).

² For the information on the rich tropical flora of the colony will be found *Surinam, Tentamen van de Natuurlijke Geschiedenis*, Amsterdam, 1831, Van der Meer, *Reis naar de Hoofdstad Suriname*, Amsterdam, 1745, Dory and Molkenboer, "Programma Florae hryologice Surinamensis," and A. Poock, "De gewinbarende cultuur Surinamensis," in *Nederl. en Schiedkundige Doelen*, Rotterdam, 1850.

cent at Paramaribo, there are three colonial and three district courts. The president and four permanent members of the supreme court are nominated by the crown. "The king," says Mr. Palgrave, "is almost every thing," the "Lords," in a consultative capacity, are something, and the "Commons" are nothing.

History.—The Dutch began to visit the coast of Guiana about 1580, and we had Adrian van Heek sending vessels thither in 1609. In 1614 the states of Holland granted to any Dutch citizen four years' monopoly of any business or place of commerce which he might discover in that region. The first settlement, however, in Surinam (in 1630) was made by an Englishman, whose name is still preserved by Kruisland Creek. When Cayenne was taken by the French in 1664 a number of Jews who had settled in that part of Guiana removed to the Surinam district, where they soon constituted an important and flourishing community. In 1666 the huge black settlement was taken by storm by the French under Guayon or Kijpman (the name is spelled in various ways), and 100,000 lb of sugar was exacted as a ransom. By the peace of Breda the Dutch were formally recognized as masters of Guiana, and though the Willemshaven, where the colonists had rights of refuge, did all they could to weaken the colony and drive off a large part of its English population to Jamaica, it continued to flourish, and was confined to the Dutch by the treaty of Westminster in 1674. For some time the Frenches claimed that they should have access to the country, but it was ultimately decided that the possession was national one in the full sense of the word. The New Dutch West India Company, founded in 1671 to replace the older company which had failed, received Guiana by charter from the States-General in 1682.¹ In the following year the company sold one-third of their territory to the city of Amsterdam, and another third to Cornelis van Assens, lord of Sommedijk. The new owners and the company undertook to plant on the land the Dutch Society of Surinam, and Sommedijk agreed to fill the post of governor of the colony at his own expense. The incentive drawn in slaves was returned by the West India Company, but this society could not post them on its own account by paying a fine to the company. Sommedijk's rule was marked by rare wisdom and energy. He oppressed and protected the Indian tribes, he erected forts and dispersed the soldiers, he constituted the court which will bear his name, he established a school, he introduced the cultivation of the cocoa nut, and in short he devoted himself in all ways to the welfare of the colony. But on 17th June 1688 he was murdered in a mutiny of his soldiers by a Dutchman, who, soon afterwards, was executed by his widow to William III. of England, but it was ultimately purchased by the city of Amsterdam for 700,000 fl. In 1713 the French, under Ousard, seized up the river and put Paramaribo to ransom, and after their departure there was no dispute between the Society and the colonists as to who should pay the indemnity. During the rest of the 18th century the chief troubles of Surinam were the Dutch negroes and the slaves. Peace with the African negroes was made in 1760, and with the Surinamians in 1762, but in 1776 the governor Nuyson still found it necessary to surround the colony with military caution against the attacks of the Bonni tribe. By the spring of 1786 plantation was complete. In 1794 the French invaded the colony, and the affairs of Surinam placed under a committee of twenty-one members. The English, who had resumed the protectorate of the colony from 1799 to 1802, took actual possession in 1804, and appointed Sir Charles Brown governor in 1807. The slave trade was abolished. At the restoration of the Dutch authority in 1815 the colonists of the district of Rickards sought to join in under English rule, or at least to recover the right of trading with English colonies. In 1817 the privileges of the Jews were annulled, and the rights of ordinary citizens bestowed on them instead. Surinam and the West Indies were placed under a common government in 1828, but the governor was to reside at Paramaribo. In 1838 several hundred slaves who had fled to the city were publicly manumitted. The emancipation of Surinam was separated from that of the West Indies in 1846. Brown was Reider, who assumed the governorship in that year, had had the colony greatly improved, and had set the slave laws, and of declaring the commerce of Guiana open to all nations at peace with the Netherlands. The suppression of slavery and the organization of immigration, as already indicated, are the main monuments of the recent history of the colony.

Among the older works on Surinam the first rank is held by Hatzsack's masterly *Beschrijving van Guiana of de Wildt Kust van Zuid Amerika*, 2 vols. 4to, Amsterdam, 1770. A valuable *Geschiedenis der Kolonie Suriname*, by J. de Meijer, of "Jesuit" Jews," was published at Amsterdam, in 1791, and it has been supplemented and so far superseded by Wolbers, *Geschiedenis van Suriname*, Amsterdam, 1801. Sketches of Surinam life are given in the form of a tale in Schack's *De Manjo Famille Teydel*

and *het Suriname'sche Volk*, Amsterdam, 1866, and a number of excellent pictures illustrating will be found in A. J. de Meijer's *Kolonie van Suriname*, Leyden, 1872, fol. The English reader is indebted to W. G. Palgrave for a valuable introduction to *Dutch Guiana*, London, 1874, a manual from the *Geographical Institute*. See also the *Handboek der Lidotheek der Koninklijke Akademie van Wetenschappen*, at Paramaribo, the *Statistiek van Suriname*, published by the *Vereniging van de Suriname'sche Algemeenheid*, published by the *Algemeenheid*, and *het Suriname'sche Volk*, Amsterdam, (H. W.)

II FRENCH GUIANA is bounded on the west by the Maroni or Marowijne, which separates it from Dutch Guiana. Towards the south and east its limits are still uncertain. According to the treaty of Utrecht in 1713 it was to be bounded towards Brazil by the river of St Vincent Pinzon, but the identification of this river has never been officially determined.² The Oyapock is accepted provisionally by both countries, but the French claim that the Arouai is the real St Vincent Pinzon, and consequently that they have a right to the country for 100 miles further south along the coast. Between the Maroni and the Oyapock the coast-line is about 130 miles. The fourteen quarters of the colony are estimated to have an area of 1,808,739 hectares, i.e., about 3,238,593 acres, or 5002 square miles, nearly as much as half the area of Belgium, but if the frontier be pushed back to the watershed, the whole area of the country could not be less than 53,000 square miles.

Surface.—A considerable portion of the low coast-land of French Guiana is occupied by swamps and marshes, the most deeply submerged of which are covered with a dense growth of mangroves, and receive the name of *paguys*, while the drier stretches are occupied by the pine or wassay palm (*Butea peccata*), and no designated prairies. In a few places, as in the Sinnamary quarter, there are peat bogs in process of formation. About 40 or 50 miles inland, where the land begins to rise, the traveller reaches the outskirts of those primeval forests which stretch back vast and vague towards the mountains. Between the narrow maritime selvas, so to speak, and the commencement of the highlands are undulating plains or savannas. Hitherto the colony has confined itself almost exclusively to the littoral and alluvial region, with its fertile mud-banks. The savannas are still in a state of nature, and though the earlier colonists made clearings in the highlands, they soon grew disappointed with the barrenness of the cold granite soil. The mountains behind Guiana do not exceed 3000 or 4000 feet of elevation, the principal range indeed, the Tumaco Range, was estimated by M. Cuvier, who crossed it in 1877, at no more than 1312 feet above the sea level. But the dense tropical forests attract so much moisture from the ocean winds that the highlands are the birthplace of a large number of rivers which in the rainy season especially pour down vast volumes of water. Upwards of twenty are counted between the Maroni and the Oyapock. United as they often are in their navigable sections by cross channels, they constitute a valuable means of communication from district to district. Omitting the Maroni already described under Dutch Guiana, the first of importance as we proceed southwards is the Mana, which is navigable for large vessels 10 miles from its mouth, and for smaller vessels 27 miles further. Passing the Sinnamary and the Konou we next come to the Cayenne, at the mouth of which lies the island on which the colonial capital is built. About a dozen lakes, of which Mepoucou, Macari, and Mapa are the largest, have been counted in the French territory.

Climate.—The rainy season begins in November or December, and lasts till the latter part of June, but there are usually three or four weeks of good weather in March

¹ Compare Mr. Cohen's Report in *Patiementairen Papers* [O1861], 1877.

² See the *Otoyot or Chartes in Hartenack, or in Verandering van Suriname, uitgegeven door de Surinaamseche Aangelegenheden, &c.* The Hague, 1847.

³ See "Mémoria sobre os limites do Brasil com a Guayana Francesa," by Dr. Casco da Silva in *Revista trimestral de Hist. e Geogr.*, Rio de Janeiro, 1850.

During the rest of the year there is often hardly a drop of rain for months. At Cayenne the annual rainfall amounts on an average to from 10 to 11 feet, and it is naturally heavier in the interior. It has been calculated indeed that, if all the fluvial outlets were blocked, a single winter would be sufficient to submerge the whole colony to a depth of 15 or 16 feet. During the hotter part of the year—August, September, October—the temperature usually rises to about 86° F, but it almost never exceeds 88°, in the colder season the mean is 79°, and it seldom sinks so low as 70°. Between day and night there is very little thermometric difference. The longest day is 12 hours 18 minutes, the shortest 11 hours 42 minutes. The prevailing winds are the N and E, and the S E, and the most violent are those of the N E. During the rainy season the winds keep between N and E, and during the dry season between S and E. Hurricanes are unknown. Sudden rises of the sea are occasionally experienced in November and December. Within the present century there have been three earthquakes (1821, 1843, and 1877), none of which did much damage.

Population.—The population of French Guiana consists of a few pure whites, negroes from Africa, mulattoes, coolies, a decreasing number of Indians, convicts from France and its colonies (among whom are many Arabs from Algeria), and Chinese, Hindis, and Anamite immigrants. In 1877 the freed population was stated at 37,530, and the floating population included about 2,900 coolies. In 1878, a military force of 1084, 938 Government officials and ecclesiastics, 4750 workmen connected with the commerce of immigration, and 1830 convicts outside of the penitentiaries, so that in round numbers the total amounted to 27,000. Of the freed population the males were 7972, and the females 9258. The widows were 1108, while the widowers were 298.

Vegetation.—French Guiana has a rich variety of trees, and several of them are attracting increasing attention from their economic value. The *Leguminosae* are abundantly represented, including the gayac (*Guaiacum guianense*, Aubl.), the coubaril or locust tree of Surinam, which grows 70 or 80 feet high without branching, the angouine (*Diospyros guianensis*), the bois violet or amaranth (*Copaiba discolor*), the pain baobab or oily tree (*Euphorbia guianensis*, Aubl.), the wicker tree or *Opuntia* (*Andinia Andrieuxii*, Benth.), the *Robinsonia* *flavescens*, the Saint Martin, and the *Albizia* *lutea*, *Schinus molle*, or tiger wood. To the family of the *Urticaceae* belong the *Pithecellobium* *guianense* or guava, the *Couatoua* *guianensis*, the *Cecropia* *guianensis* or monkey tree, and the *Albizia* *lutea*, which is also known. The other species of *Leguminosae*, to the *Euphorbiaceae*, the *Mimosa* *guianensis*, the *Juncea* *guianensis*, and the *Albizia* *lutea*, and the *Albizia* *lutea* *guianensis*. Of the *Urticaceae* it is enough to mention the black cedar (*Acacia guianensis*), the boysen or boysen tree, and several species of *Acacia*. Among the palms are the coco-palm, the oil-palm of Africa, and the date palm. The timber of the coubaril, the bois violet, and the balata has been found to be of very high excellence. *Conocarpus* (*Eleusine guianensis*) is common in the contested territory in the south, the *Albizia* *lutea* (*Albizia guianensis*) and the *Albizia* *lutea*, which also yields a medicinal resin, are abundant in the country. Large quantities of elegant seeds might be collected from the *Albizia* *lutea* (*Albizia guianensis*) and the *Albizia* *lutea* (*Albizia guianensis*).

The manioc is the principal source of food in French Guiana, and is becoming an important object of cultivation, and maize, yams, sweet potatoes, and the bread fruit are also known. The Guiana cocoa is excellent, coffee, introduced in 1716, is extensively grown, and vanilla is one of the common wild plants of the country. The cane has been acclimatized, and in the latter part of the century it formed a good source of wealth. The cinnamon tree was also successfully introduced in 1772, but like that of the pepper tree and the nutmeg its cultivation is neglected.

Minerals.—Of great interest, especially to the gold of Guiana, which promises, or threatens, to modify the life of the colony. Indian traditions affirmed the presence of the precious metal, and Humboldt and Buffon agreed that the geological character of the country indicated the probability of any such deposits, but it was not till 1819 that Felix Cécé, at the instigation of a Portuguese Indian named Pauline, discovered and opened the first "placer." In 1866 the Approuague company was formed, but, though 6769 acres were collected between 1866 and 1877, it soon after sold its rights. The Martony company has been more successful, 23,342 oz of gold

was obtained in 1872, 46,044 oz., equal to 4 million francs, was exported from Cayenne in 1874, and in 1876 and 1877 the yield was 4828 oz per month. As various fugacious minerals are abundant in some places, it is possible that not one may exist.

Commerce.—The total value of the imports into French Guiana in 1871 was 5,603,413 francs, and it exported to the value of 2,566,158 francs to France, 10,600 francs to the French colonies, and 118,849 francs abroad. It is with Martinique that it stands in the closest commercial relations, but the imposition in 1872 of a duty on the wine from that island has almost put a stop to its importation. Several small steamers maintain communication between different parts of the colony.

Colonial Establishments.—It was in 1861 that Guiana was recommended to the French Government by a special commission of inquiry as a suitable place for criminal penitentiaries. In January 1862 transportation thither was official as a favour to the convicts then under sentence, and more than 3000 of them were to be sent there. As the inmates of the colonies are allowed by a decree of 1863 to send to Guiana any Asiatics or Africans who are condemned to hard labour or solitary confinement, and as it has been decreed since 1864 to take the European convicts to New Caledonia, the criminal establishment of the penitentiaries thither is mainly negroes, Arabs, and Americans. The principal establishments are those of Cayenne, of the Prince des Isles, of the Amazon, and of the Maroni. The little island La Mère is reserved for the aged, the infirm, and the convicts. At Saint Laurent on the Maroni there is almost a little town of wooden houses built on brick pillars. The convicts carry on their social trade as carpenters, masons, bakers, &c. After two years in the colony, they whose conduct has been satisfactory are allowed to contract marriage, and to quit home for their families, to leave a piece of money assigned to them for cultivation, and to receive the necessary tools. The houses have been constructed for the use of the "convicts" (*See Rio Col et Mar, 1878*).

Administration.—Besides the governor and the military commandant, the administrative personnel comprises an ordonnateur, a director of the interior, and a procurator general, as well as a pay council and a director of the penitentiary service. There is a court of appeal and a tribunal of first instance, and justices of the peace are appointed at each station. The colony is divided into 11 municipal councils. Religious affairs are under an apostolic prefect.

History.—According early to the French writers, the history of Guiana is little better than a series of disasters. La Ravennais, sent out in 1663 by Henry IV to explore the country, brought back a favourable report, but the death of the king put a stop to the projects of formal colonization. In 1686 a small body of traders from Rouen settled on the Sinnamary, and in 1704 a similar band took up their quarters at Cayenne. The Compagnie du Cay Nord, founded by the people of Rouen in 1613, the Compagnie du Cay, the Compagnie de la Guayenne, established in 1616, and the second Compagnie de la Guayenne, established in 1624, were all unsuccessful. In 1674 the colony passed under the direct control of the crown, and the administration of Colbert began to take form in its progress. They in 1769 was marked by a terrible disaster. (Humboldt, *Essai sur l'histoire naturelle de la Guayenne*, &c.) In 1769 a Frenchman a companion of the country between the Maroni and the Amazon, went out about 12,000 volunteer colonists, mainly from Alverne and Lorraine. They were landed at the mouth of the Maroni, and were to suffer from the severe fever that struck them there. A long investigation by the parliament of Paris proved only that some one had blundered. Several minor attempts at colonization in Guiana were made in the latter part of the century, but they all ended in failure from the same fatal cause of fever. During the terrible times of the Revolution French Guiana had not of political persons were transported to Guiana. The fate of the colonies, previously 600 in number who were exiled on the 18th of July, was especially sad. Landed on the Sinnamary, they were in 1793, two thirds of them perished miserably. In 1800 a French Guianese was appointed governor, and he managed to put the colony in a better state, but in 1809 his career was brought to a close by the invasion of the Portuguese and the English. French Guiana was nominally restored to the French in 1811, but it was not recognized by the Portuguese till 1817. In 1823, at the suggestion of M. Calmann Laroche, an attempt was made to settle a colony of French emigrants in the basin of the Sinnamary, but they were soon driven by fevers from the town of Nonville. Another colony had been founded. Since that date the principal facts in the history of the unfortunate country are the discovery of its gold fields and the introduction of the convict establishments.

A detailed bibliography of French Guiana will be found in Ternaux-Compans, *Notice Historique de la Guyane française*, 1848; and in Victor de Noyon, *Extraits des auteurs et voyageurs qui ont écrit sur la Guyane*, 1844. Among the works of the present century are—Le Clercq, *Considérations géographiques de la Guyane française*, 1843; Burnard, *Coup d'œil sur le climat, agricole de la Guyane française*, 1843; Motzom, *Mémoire de Cayenne*, 1857; Vidal, "Voy. d'exil, dans le haut Maroni," in *Rev. mar.* et col., 1862; Gouy, *Banville, sur l'avenir, les élans et les réserves de la Guyane française*, 1865 (Dépôt de la marine); Bouyer, *Notes et Souvenirs*, 1867; Sogot, "Exploitation des forêts," in *Rev. mar.* et col., 1868, and *Agri-culture de la Guyane française*, 1874; Delisle, *Voy. chez les Indiens*, 1870; Jaffré, de Saint-Gaudens, *Introduction à l'Hist. de Cayenne*, 1872; Barvenau, "L'or à la Guyane française," in *Rev. mar.* et col., 1878; Mourid, *La Guyane française*, 1874; Crovisier, *Le Guy. en Guyane*, 1877; in *Bull. de la Soc. de Géogr.*, 1878, and in *Tour du Monde*, 1878; *Antiquaire des produits des Colonies françaises* (Exposition 1878), 1878; and Galliard, *Les colonies françaises*, 1880.

GUIBERT (1058–1124), of Nogent, a theological and historical writer, who flourished at the close of the 11th and the beginning of the 12th century, was born of rich and noble parents at Clermont-en-Beauvoisis on Easter Eve 1058. Dedicated from infancy to the service of God and the Virgin, he received his early education at the Benedictine abbey of Fleury (Flaviacum) or St Germer, in the diocese of Beauvais; there he gave himself with great zeal to study, but chiefly of the secular poets, until a severe illness brought about a crisis in his spiritual life, in consequence of which he began to fix his attention almost exclusively upon the Holy Scriptures and the writings of the fathers, especially of Augustine and Gregory the Great. About this period he was largely influenced by personal intercourse with Anselm, afterwards of Canterbury, who, at this time, was head of the priory of Bee in the neighbourhood of St Germer's. Encouraged by his friend he now devoted his energies to Old Testament exegesis, and wrote a commentary upon the narrative of the creation; this was followed by other literary works both in verse and in prose. In 1104, when he had completed his fiftieth year, he was chosen to be head of the abbey of Notre Dame de Nogent, and there the remainder of his life was spent in a high degree of theological and ecclesiastical activity. He died in 1124.

His works, edited by D'Achery, were first published in 1651, in one volume folio, at Paris (*Patrologia Guibertii Abbatis B. Marie de Norwington Opera Omnia*); they include, besides minor works, a treatise on Homiletics (*Liber qui ordinem sermo fieri debet*); ten books of *Moralia* on Genesis, begun in 1084, but not completed until 1110, composed of the treatise of Gregory the Great *Homilies in Joban*; five books of *Tropologia* on Hosea, Amos, and the Lamentations; a treatise on the Incarnation, against the Jews; four books *De Significatione Spirituum*, remarkably free opinions on the abuses of saint and relic worship; eight books of the *Historia qui dicitur Gesta Dei per Francos*, also *Historia Hierosolymitana*, a history of the first crusade, which constitutes one of our best authorities on the events with which it deals; and three books *De Vita Sua*, also *Monodiarum*. See Migne's *Patrologia Latina*, vols. cxi. and cxcix.

GUIBERT, or WIDERT (c. 1030–1100), of Ravenna, better known as the antipope Clement III., was born of noble parents in the 11th century at Parma, where, on attaining the canonical age, he entered the priesthood. During the minority of Henry, Guibert was appointed by the empress Agnes to be chancellor of the kingdom of Italy; and in this capacity he steadfastly resisted, in the interests of the crown, the innovations of Hildebrand in relation to papal elections. For his services in this he was rewarded with the archbishopric of Ravenna, to which he was consecrated in 1078; his fidelity to Henry during the struggles which followed Hildebrand's accession to the papal throne as Gregory VII. led to his being ecclesiastically suspended in 1075. By thirty bishops of the imperialist party he was elected pope at Brixen in 1080, an election which was confirmed by the synod which Henry had convened in Rome in 1084, Guibert assuming the title

of Clement III. Although it was from his hands that Henry received his coronation, Clement III. held scant recognition from the clergy and exercised few royal functions; and his name is not enrolled in any list of popes. He died in September 1100, and was buried at Ravenna; by the order of Paschalis II. his ashes were afterwards disinterred and scattered to the winds. See Giesebrecht's *Kaisergeschichte*, vol. iii.

GUICCIARDINI, FRANCESCO (1483–1540), the celebrated Italian historian and statesman, was born at Florence in the year 1483, when Marsilio Ficino held him at the font of baptism. His family was illustrious and noble; and his ancestors for many generations had held the highest posts of honour in the state, as may be seen in his own genealogical *Ricordi* (*Op. Ined.*, vol. x.). After the usual education of a boy in grammar and elementary classical studies, his father, Piero, sent him to the universities of Ferrara and Padua, where he stayed until the year 1505. The death of an uncle, who had occupied the see of Cortona with great pomp, induced the young Guicciardini to hanker after an ecclesiastical career. He already saw the scarlet of a cardinal awaiting him, and to this eminence he would assuredly have risen. His father, however, checked this ambition, declaring that, though he had five sons, he would not suffer one of them to enter the church, lest the state of corruption and debasement. Guicciardini, whose motives were confessedly ambitious (see *Antiblog.*, *Ricordi*, *Op. Ined.*, x. p. 68), turned his attention to law, and at the age of twenty-three was appointed by the signoria of Florence to read the *Institutes* in public. Shortly afterwards he engaged himself in marriage to Maria, daughter of Alamanno de' Salviati, prompted, as he frankly tells us, by the political support which an alliance with that great family would bring him (*Id.*, x. 71). He was then practising at the bar, where he won so much distinction that the signoria, in 1512, entrusted him with an embassy to the court of Ferdinand the Catholic. Thus he entered on the real work of his life as a diplomatist and statesman. His conduct upon that legation was afterwards severely criticized; for his political antagonists accused him of betraying the true interests of the commonwealth, and using his influences for the restoration of the exiled Casa Medici to power. His Spanish correspondence with the signoria (*Op. Ined.*, vol. vi.) reveals the extraordinary power of observation and analysis which was a chief quality of his mind; and in Ferdinand, hypocritical and profoundly dissimulative, he found a proper object for his astute study. To suppose that the young statesman learned his frigid statecraft in Spain would be almost too simple a solution of the problem offered by his character, and scarcely fair to the Italian proficients in perfidy. It is clear from Guicciardini's autobiographical memoirs that he was ambitious, calculating, covetous, and power-loving from his earliest years; and in Spain he had no more than an opportunity of studying on a large scale those political vices which already ruled the minor potentates of Italy. Still the school was pregnant with instructions for so apt a pupil. Guicciardini issued from this first trial of his skill with an assured reputation for diplomatic ability, as that was understood in Italy. To unweave plots and weave counterplots, to meet treachery with fraud; to parry force with sleights of hand; to credit human nature with the basest motives, while the basest crimes were contemplated with cold enthusiasm for their cleverness, was reckoned then the height of political sagacity. Guicciardini could play the game to perfection. In 1515 Leo X. took him into service, and made him governor of Reggio and Modena. In 1521 Parma was added to his rule, and in 1523 he was appointed viceroy of Romagna by Clement VII. These high offices rendered Guicciardini the virtual master of the papal states beyond the Apennines, during a period of great bewilder-

ment and difficulty. The copious correspondence relating to his administration has recently been published (*Op. Ined.*, vols. vii, viii). In 1528 Clement gave him still higher rank as lieutenant general of the papal army. While holding this commission, he had the humiliation of witnessing from a distance the sack of Rome and the imprisonment of Clement, without being able to rouse the perfidious duke of Urbino into activity. The blame of Clement's downfall did not rest with him, for it was merely his duty to attend the camp, and keep his master informed of the proceedings of the generals (see the Correspondence, *Op. Ined.*, vols. iv, v). Yet Guicciardini's conscience accused him, for he had previously counselled the pope to declare war, as he notes in a curious letter to himself written in 1527 (*Op. Ined.*, x, 104). Clement did not, however, withdraw his confidence, and in 1531 Guicciardini was advanced to the governorship of Bologna, the most important of all the papal lord-leutenancies (Correspondence, *Op. Ined.*, vol. ix). This post he resigned in 1534 on the election of Paul III., preferring to follow the fortunes of the Medicean princes. It may here be noticed that though Guicciardini served three popes through a period of twenty years, or perhaps because of this, he hated the papacy with a deep and frozen bitterness, attributing the woes of Italy to the ambition of the church, and declaring he had seen enough of sacerdotal abominations to make him a Lutheran (see *Op. Ined.*, vol. i, 27, 104, 95, and *Id. of Id.*, ed. Roe, ii, 218). The same discord between his private opinions and his public actions may be traced in his conduct subsequent to 1534. As a political theorist, Guicciardini believed that the best form of government was a commonwealth administered upon the type of the Venetian constitution (*Op. Ined.*, i, 6, ii, 130 sq.), and we have ample evidence to prove that he had judged the tyranny of the Medici at its true worth (*Op. Ined.*, vol. i, 171, on the tyrant, the whole *Storia Fiorentina* and *Reggimento di Firenze*, vi, i and ii, on the Medici). Yet he did not hesitate to place his powers at the disposal of the most vicious members of that house for the enslavement of Florence. In 1527 he had been declared a rebel by the signoria on account of his well-known Medicean prejudices, and in 1530, punished by Clement to punish the citizens after their revolt, he revenged himself with a cruelty and an avarice that were long and bitterly remembered. When, therefore, he returned to inhabit Florence in 1534, he did so as the creature of the dissolute Alessandro de' Medici. Guicciardini pushed his servility so far as to defend this infamous despot at Naples in 1535, before the bat of Charles V., from the accusations brought against him by the Florentine exiles (*Op. Ined.*, vol. ix). He won his cause, but in the eyes of all posterity he justified the reproaches of his contemporaries, who describe him as a cruel, venal, grasping seeker after power, eager to support a despotism for the sake of honours, offices, and emoluments secured for himself by a bargain with the oppressors of his country. Varchi, Pitti, Segni, and Nardi are unanimous upon this point, but it is only the recent publication of Guicciardini's private MSS. that has made us understand the force of their invectives. To plead loyalty or honest political conviction in defence of his Medicean partisanship is now impossible, face to face with the opinions expressed in the *Ricordi Politici* and the *Storia Fiorentina*. Like Machiavelli, but on a lower level, Guicciardini was willing, in the depth of his soul, he detested and despised. After the murder of Duke Alessandro in 1537, Guicciardini espoused the cause of Cosimo de' Medici, a boy addicted to field sports, and unused to the game of statecraft. The wily old diplomatist hoped to rule Florence as grand vizier under this inexperienced prince. He was mistaken, however, in his schemes, for Cosimo displayed the genius of his family

for politics, and coldly dismissed his would-be lord protector. Guicciardini retired in disgrace to his villa, where he spent his last years in the composition of the *Storia d'Italia*. He died in 1540 without male heirs.

Guicciardini was the product of a cynical and selfish age, and his life illustrated its sordid influences. Of a cold and wildly temperamental, devoid of passion, blameless in his conduct as the father of a family, faithful as the servant of his papal patrons, severe in the administration of the provinces committed to his charge, and indubitably able in his conduct of affairs, he was at the same time, and in spite of these qualities, a man whose moral nature repudiated a sentiment of highest reputation. It is not merely that he was ambitious, cruel, revengeful, and avaricious, for these vices have existed in men far less antipathetic than Guicciardini. Over and above these faults, which made him odious to his fellow citizens, we trace in him a meanness that our century is less willing to condone. His phlegmatic and persistent egotism, his sacrifice of truth and honour to self-interest, his acquiescence in the worst conditions of the world, if only he could use them for his own advantage, combined with the glaring discord between his opinions and his practice, form a character which would be contemptible in our eyes were it not so smothered. The social and political descriptions of Italy, whose patriotism was unknown and cold, which showed us all the motives that rouse man to action, found in his representative and exponent in Guicciardini. When we turn from the man to the author, the decadence of the age and race that could develop a political philosophy so cold in its cynical despair of any good in human nature forces itself vividly upon our notice. Guicciardini seems to glory in his disillusionment, and uses his vast intellectual ability for the analysis of the corruption he had helped to make incurable. If one single trait of that century should be chosen to represent the spirit of the Italian people in the last phase of the Renaissance, the historian might hesitate between the *Principe* of Machiavelli and the *Ricordi Politici* of Guicciardini. The latter is perhaps preferable to the former on the score of comprehensiveness. It is, moreover, more exactly adequate to the actual situation, for the *Principe* has a divine spark of patriotism yet lingering in the corner of its frigid reason, an idealistic enthusiasm surviving in its moral aberrations, whereas a great Italian critic of this decade has justly described the *Ricordi* as "Italian corruption codified and elevated to a rule of life." Guicciardini is, however, better known as the author of the *Storia d'Italia*, that vast and detailed picture of his country's sufferings between the years 1494 and 1532. Judging him by this masterpiece of scientific history, he deserves less commendation as a writer than as a thinker and an analyst. The style is wearisome and prolix, attaining to procrustean the expense of circumlocution, and setting forth the smallest particulars with the same distinctness as the main features of the narrative. The whole tangled skein of Italian politics, in that involved and stormy period, is unravelled with a patience and an insight that are above praise. It is the crowning merit of the author that he never ceases to be an impartial spectator,—a cold and curious critic. We might compare him to an anatomist, with knife and scalpel dissecting the dead body of Italy, and pointing out the symptoms of her manifold diseases with the indifferent analysis of one who has no moral sensibility. This want of feeling, while it renders Guicciardini a model for the scientific student, has impaired the interest of his history. Though he lived through that agony of the Italian people, he does not seem to be aware that he is witnessing a great historical tragedy. He takes as much pains in laying bare the trifling causes of a petty war with Pisa as in probing the deep-seated ulcers of the papacy. Nor is he capable of painting

the events in which he took a part, in their totality as a drama. Whatever he touches, lies already dead on the dissecting table, and his skill is that of the analytical pathologist. Consequently, he fails to understand the essential magnitude of the task, or to appreciate the vital vigour of the forces contending in Europe for mastery. This is very noticeable in what he writes about the Reformation. Notwithstanding these defects, inevitable in a writer of Guicciardini's temperament, the *Storia d'Italia* was undoubtedly the greatest historical work that had appeared since the beginning of the modern era. It remains the most solid monument of the Italian reason in the 16th century, the final triumph of that Florentine school of philosophical historians which numbered Machiavelli and Vettori, Segni, Pitti, Nardi, Nelli, Varchi, and Giannotti. Up to the year 1837 the fame of Guicciardini as a writer, and the estimation of him as a man, depended almost entirely upon the *History of Italy*, and on a few ill-edited extracts from his aphorisms. At that date his representatives, the Counts Piero and Luigi Guicciardini, opened their family archives, and committed to Signor Giuseppe Ganeschini the publication of his hitherto unnoticed MSS. in ten important volumes. The vast mass of documents and finished literary work thus given to the world has thrown a flood of light upon Guicciardini, whether we consider him as author or as citizen. It has raised his reputation as a political philosopher into the first rank, where he now disputes the place of intellectual supremacy with his friend Machiavelli, but it has coloured our moral judgment of his character and conduct with darker dyes. From the stores of valuable materials contained in those ten volumes, it will be enough here to cite (1) the *Ricordi Politici*, already noticed, consisting of about 400 aphorisms on political and social topics; (2) the observations on Machiavelli's *Discorsi*, which bring into it an inalienable relief the views of Italy's two great theorists on statecraft in the 16th century, and show that Guicciardini regarded Machiavelli somewhat as an amiable visionary or political enthusiast; (3) the *Storia Fiorentina*, an early work of the author, distinguished by its animation of style, brilliancy of portraiture, and liberality of judgment; and (4) the *DIALOGO del Reggimento di Firenze*, also in all probability an early work, in which the various forms of government suited to an Italian commonwealth are discussed with infinite subtlety, contrasted, and illustrated from the vicissitudes of Florentine history from 1494 to 1530. There may be while a series of short essays, entitled *Discorsi Politici*, composed during Guicciardini's Spanish legation. "It is only after a careful perusal of these minor works that the student of history may claim to have comprehended Guicciardini, and may feel that he brings with him to the consideration of the *Storia d'Italia* the requisite knowledge of the author's private thoughts and jealously guarded opinions. Indeed, it may be confidently affirmed that those who desire to gain an insight into the true principles and feelings of the men who made and wrote history in the 16th century will find it here far more than in the work designed for publication by the writer." Taken in combination with Machiavelli's treatises, the *Opere Inedite* furnish a comprehensive body of Italian political philosophy anterior to the data of Fra Paolo Sarpi.

The student may be referred to Rowen's edition of the *Storia d'Italia*, Pisa, 1819, 10 vols., and to the *Opere Inedite*, in 10 vols., published at Florence, 1857. These two books place him in possession of all that is extant of Guicciardini. (J. A. S.)

GUIDI, CARLO ALESSANDRO (1680-1712), Italian lyric poet, was born at Pavia in 1680. As chief founder of the well-known Roman academy called "L'Arcadia," he had a considerable share in the reform of Italian poetry, corrupted at that time by the extravagance and bad taste of the poets Marino and Achillini and their school. The

poet Guidi and the critic and jurisconsult Gravina checked this evil by their influence and example. The genius of Guidi was lyric in the highest degree, his songs are written with angular force, and charm the reader, in spite of touches of bombast. His most celebrated song is that entitled *Alla Fortuna* (To Fortune), which certainly is one of the most beautiful pieces of poetry of the 17th century. Guidi was squint-eyed, humpbacked, and of a delicate constitution, but possessed undoubted literary ability. His poems were printed at Parma in 1671, and at Rome in 1704. In 1681 he published at Parma his lyric tragedy *Amulius rex Italy*, and two pastoral dramas *Daydine* and *Endymion*. The last had the honour of being mentioned as a model by the critic Gravina, in his treatise on poetry. Less fortunate was Guidi's poetical version of the six homilies of Pope Clement XI., first as having been severely criticized by the satirist Settano, and next as having proved to be the indirect cause of the author's death. A splendid edition of this version had been printed in 1712, and the pope being then in San Gaudolfo, Guidi went there to present him with a copy. On the way he found out a serious typographical error, which he took so much to heart that he was seized with an apoplectic fit at Frascati and died on the spot. Guidi was honoured with the special protection of Ranuccio II., duke of Parma, and of Queen Christina of Sweden.

GUIDICCIONI, GIOVANNI, one of the best Italian poets of the first half of the 16th century, was born at Lucca in 1480, and died at Macerata in 1541. He occupied a high position, being bishop of Fosombrone and president of Romagna. The latter office nearly cost him his life, a murderess attempted to kill him, and had already touched his breast with his dagger when, conquered by the resolute calmness of the prelate, he threw away the weapon and fell at his feet, asking forgiveness. The *Verse* and *Letters* of Guidiccioni are models of elegant and natural Italian style. The best editions are those of Genoa (1749), Bergamo (1753), and that recently published at Florence.

GUIDO or ANZEO, an Italian monk of the 11th century, has by many been called the father of modern music, and a portrait of him in the refectory of the monastery of Avellana bears the inscription "Beatus Guido, inventor musicæ." Although these statements are manifestly exaggerated, it is none the less true that Guido's reforms mark an enormous progress in the nation as well as in the teaching of music. Of his life little is known, and what little is chiefly derived from the dedicatory letters prefixed to two of his treatises and addressed respectively to Bishop Theodald (not Theobald, as Bunce writes the name) of Alesso, and Michael, a monk of Pomposa and Guido's pupil and friend. Occasional references to the celebrated musician in the works of his contemporaries are, however, by no means rare, and from these it may be conjectured with all but absolute certainty that Guido was born in the last decade of the 10th century. The place of his birth is, beyond a doubt, Alesso, for on the title-page of all his works he is styled *Guido Aretino*, or simply *Aretino*. At his first appearance in history Guido was a monk in the Benedictine monastery of Pomposa, and it was there that he invented his educational method, by means of which, according to his own statement, a pupil might learn within five months what formerly it would have taken him ten years to acquire. Envy and jealousy, however, were his only reward, and by these he was compelled to leave his monastery—"inde est, quod me vides prolixius finibus exulatum," as he says himself in the second of the letters above referred to. According to one account, he travelled as far as Bremen, called there by Archbishop Hermann in order to reform the musical service. But this statement has been doubted, for chronological and other reasons.

Fourmont, whom in 1745 he succeeded at the Royal Library as society interpreter of the Eastern languages. *A Mémoire Historique sur l'Origine des Huns et des Turcs*, published by De Guignes in 1748, having brought his name with some prominence before the learned world, he was admitted a member of the Royal Society of London in 1762 and an associate of the French Academy of Inscriptions in 1754. Two years later he gave to the world the first two volumes of his learned and laborious *Mémoires Générales des Huns, des Mongoles, des Turcs, et des autres Tartares occidentaux*, and in 1757 he was appointed to succeed Jankin in the chair of Syriac at the Collège Royal. The completion of the *Mémoires* by the publication of the three remaining volumes in 1768 was followed in 1759 by the publication of a *Mémoire* in which he propounded and endeavored to prove the untenable and absurd theory that the Chinese nation had originated in Egyptian colonization, an opinion to which, in spite of every argument, he to the last obstinately clung. To its support, as also to the further elucidation of the chronology and arrangement of his *Histoire*, which had been, not without some justice, unfavourably criticised, he devoted several learned papers which are to be found in the *Mémoires* of the Academy of Inscriptions, and among his other literary labours, an improved edition of an old translation of the *Shoo King* is worthy of special notice. The publication, by permitting De Guignes to attain some insignificant pensions which had been conferred upon him, deprived him of various posts, such as those of keeper of the antiquities in the Louvre and editor of the *Journale des Savans*, on which he was chiefly dependent for his income, and his later years are said to have brought to him considerable personal hardship, from which his sole refuge was in indolent application to study. He died at Paris, March 19, 1800. The *Histoire* had been translated into German by Dineht (1768-71). De Guignes left a son, Christian Louis Joseph (1759-1846), who, after leaving China from his father, went as consul to Canton, where he spent seventeen years. On his return to France he was charged by the Government with the work of preparing a Chinese-French-Latin dictionary. Though bearing his name alone on the title-page (1813), it was in reality only a new edition of the work of Glomona. He was also the author of a huge work of travels (*Voyages à Pékin, Mouille, et à la Baie de Paoi*, 1808).

(GUILD) The spirit of association has in all ages induced men to join together for the pleasures of mutual enjoyment or for the attainment of some common purpose for which the support of number was necessary. The idea has taken shape in various ways, influenced by the temperament of race, the policy of Governments, the social condition of classes, or the need for a special object. Independently of the organization of peoples, of their constitution into towns, provinces, and states as units in a system, whether of self government or of imposed government,—independently too of those great associations or brotherhoods, the church, the orders of knighthood, the greater and lesser monastic orders, and secret societies,—there is a third kind of association upon a basis distinct from these. The public welfare of a community within certain territorial limits is the great object of Governments, local or imperial, the pursuit of some great moral, religious, or equitable thought, touching the hearts of men in general without regard to nation, was the animating principle of the chivalric and religious orders, but when men began to turn themselves into guilds, the benefit of each one in his individual and social capacity was concerned, naturally confined within the bounds of neighbourhood. A guild was a voluntary association of those living near together who joined for a common purpose, paying contributions, worshipping together, feasting together periodically, helping one another in sick-

ness and poverty, and frequently united for the pursuit of a special object.

The true history of these institutions has been till recently unnoticed, their value and importance, especially in connexion with the life of towns and villages, having been but imperfectly investigated or understood. Guilds have, however, been numerous, and their influence most important, in Europe from an early period, they attained their highest prosperity and development in the Teutonic countries, and especially in England during the Middle Ages, and they have been widely spread among the Romanic nations.

The meaning of the word *guild* or *gild* is closely connected with the origin of the institution. *Gild* or *gild* was Old English for a set payment or contribution, from *gidan* or *gidan*, to pay (whence also the present *yield*), the primary meaning was payment, and the company of those who paid became known by this chief title to membership. There are also *gilde*, Danish and Low German, in the sense of a contributory company of this kind, *gilde* and *gilde*, Icelandic, a payment, and *gilde*, also a banquet. The word therefore, thus derived, is better *spelt* (as most old authorities have it) without the *u*, a colour is, however, given for the ordinary modern form *guild*, by deriving it (as Wedgwood, *English Etymology*) from the Welsh or Breton *gwyl*, a feast or holiday, *gwylad*, keeping, a festival.

The essential principle of the guild is the banding together for mutual help, mutual enjoyment, and mutual encouragement in good endeavour. The spirit which directed itself to the mutual business and life of each society and its members is the true mark, in some degree, of all bodies, ancient or modern, that can claim the character of guilds. The peace guild of the North in the 10th century had this character in common with the great trading guild of the 13th and 14th centuries, or the little social or religious guild of an English country village of a century later.

Some German scholars find the origin of the first guilds in the banquets and secular assemblies of the Southern German tribes. Wille, Dr L. Biondani, and others, connecting these with what is known of the importance of family relations among the Teutonic nations, find in the family union the germ from which the guild was developed, and show that when Christianity was brought from the south of Europe "the spirit of association received a mighty impulse, and the guilds spread themselves rapidly under the influence of Christian doctrine" (Biondani). It is maintained by others that the guilds have sprung from the *collegia*, in those countries where the Romans bore sway.

The Romans exercised the right of association from early times, it is attributed to Numa that he encouraged the formation of crafts guilds, of which Plutarch enumerates nine, there also existed early religious societies among them. Enacted voluntarily under the republic, this right became crippled under the empire, and the *collegia* were obliged to seek authorization from the state for the narrower objects to which the imperial decrees attempted to limit them. These societies were numerous, not only at Rome, but throughout the empire, especially in the East, in Italy, and in Gaul, a large number were trade corporations, devoted to the interest of their crafts, others were united for good-fellowship, religion, and many especially to provide for burial. In the provinces, besides merchants and others, the highest persons were glad at times to belong to them, those in Rome under the empire appear to have consisted principally of workmen, freedmen, slaves, and persons of the humbler classes. All appear to have had the same general features, they chose their own masters and officers, made rules for self-government, paid contributions to a common fund, met and feasted together at stated periods, the freedom of social intercourse being particularly ap-

perceived among the poorer companies. They formed rules for good behaviour at table, and admitted women as members, they "affirmed their existence by a common worship," choosing a patron god. From these and other resemblances Mr H C Coote contends that there is an identity between the Roman *collegia* and the guilds of Saxon growth, and Mr Raynolds is an advocate of a similar descent in France and Italy. But though analogous in many respects, as far as is known they lacked the essential element of the guild, that of mutual help in sickness and poverty, the soldiers' colleges, formed in spite of the law which forbade them, approach the nearest to the character, in providing their members with travelling expenses and relieving pensions. The evidence against the connexion between the *collegium* and the guild is regarded by the ablest German writers who have investigated the subject as conclusive, but this interesting historical question has not yet been fully worked out.¹

The Greeks also, in the 2d and 3d centuries B.C., had their associations of the same kind, called *Eranos* or *Thesoi*, which were numerous at Rhodes, in the islands of the Archipelago, at the Pireus, and in other important places. These societies partook more nearly of the character of the medieval guilds than did the Roman, the members paid contributions to a general fund, added, one another necessary, provided for funerals, met in assembly to deliberate on their affairs, and celebrated feasts and religious sacrifices in common. Strict rules against disorderly conduct were to be enforced by fine, he who did not pay his yearly quota to the society was excluded, unless he could show good cause of poverty or sickness. Women could be members, and were admitted to the meetings. Some of these societies concerned themselves with religion, others with politics or commerce, in the course of liberal as opposed to official religion, they appear to have done good service.

It is perhaps of little use attempting to ascribe to any one country or race the special initiative of these institutions, any more than it would be to say that the custom of men to congregate in towns originated with this or that nation. Human nature is the same everywhere, and two motives induce men to join together—weakness, seeking the power of numbers for resisting oppression, or for mutual assistance, and the affinity which those pursuing the same occupation and possessing the same interests have for each other. These motives are sufficient to account for the existence of the *Eranos* in Greece, contemporary with the *Collegia* of the Romans, they are sufficient to explain why, although the *collegia opificum*, or artisans' guilds, are found as late as the code of Justinian, and that 50 or 60 years later, in the 6th century, we have record of a soap-makers' craft in Naples (Letter of Pope Gregory the Great, lib. a. epist. 26, Migne's *Pat. Cur.*, vol. lxxvii), the guilds in the towns of Italy should begin a new life in the 10th century (Hegel), they can explain why in England we find from the 7th to the 10th century other guilds actively in existence, while in Norway they were instituted in the 11th century. These societies "may thus have one history in China, another in India, another in Greece or Rome, another in the Europe of the Middle Ages, the like needs will require the like kinds of help, and develop institutions which, amid whatever diversities of outward garb, will substantially fulfil the same ends" (J M Ludlow).

In the Middle Ages guilds are recognized as belonging to three or four classes. In the north of Europe the *frith*

or *peace guild* was an important form, widely spread in early times. These were associations for defence, based upon mutual obligations, " sworn communities for the protection of rights and the preservation of liberty," we see traces of them in England from the laws of Ina (7th century) down to the "Dooms" of London in Athelstan's time (10th century). These statutes of the old London peace guild are thus shortly described by Prof Stubbs—

"A monthly meeting is directed, at which there is to be by filling and a selection, the members of which are to be selected in time on the death of a member each brother gives 10d. and sings or prays for the angling of fifty palms. Each member pays fourpence for common purposes, towards a sort of insurance fund from which the guild makes good the losses of members, and a contribution of a shilling towards the payment of the tithes. The members are arranged in bodies of ten, out of whom is the headman, these again are classed in tens under a common leader, who with the other headmen acts as the usual and judicial of the hundred members."

The early English recognized the responsibility of the guild for the actions of its members and their mutual liability,—the fundamental principle of English institutions for keeping the peace, besides this, the rules still exist of Saxon guilds at Abbotbury, Woodbury, Cambridge, and Exeter, and show by the many points in common with the social guilds of later English growth whence these derived their descent. Abroad, the *frith* guilds in the 11th and 12th centuries extended over the Continent, one of the most remarkable was founded at Roskilde, under King Canute, for the suppression of the piracy of the vikings. Others, as in Schleswig, Artois, Flanders, &c, joined for hindering violence and maintaining peace, by all means that law and custom allowed, even against kings. These guilds became of such importance that in many places their law grew to be that of the *commune* or town (see Bonovon). In France the great development of town governments at this period was frequently but the acknowledgment of an already existing defensive guild, or of the important merchant or craft guilds. At Montpellier and Paris, in the beginning of the 13th century, the trade guilds took part in the watch and ward of the city, and thus were a recognized part of the *commune*. The same was the case in London in early times. Even as late as the 15th century a guild was founded at Ghent, composed of the culvermeins, arquebusers, and gunners, in order to teach the burghers the use of firearms, so as to be able to defend the town on suppress troubles. It became the chief guild of the city, had public festivities, admitted women as "consoeurs," and possessed many of the features of both peace and social guilds.

In the Frankish empire guilds were numerous for defence, for conviviality, and for religious and social duties, among the serfs and the clergy as well as others, but under Charlemagne and his successors they suffered great oppression, and were persecuted by both ecclesiastical and secular authorities. In later times the clergy formed special societies called *Guilds of Kalenders*, so named from their meeting day having originally been on the kalends of each month (Brentano), these were to be found in many towns on the Continent, sometimes we read of the major and minor guilds for the higher and lower clergy. The only company that is known to have partaken of this character in England was the ancient Guild of the Kalenders at Bristol, which kept the records of that town and other places, and in its later years supported a school for Jews.

A class of guilds widely spread in the Middle Ages, especially in England, were those which have been distinguished by the name of *Sociati* (Toulmin Smith) or *Religiosi*

¹ For a valuable sketch of the *Collegia*, including trade guilds and burial guilds, see "Les sociétés ouvrières à Rome," by Gaston Bousquet, *Revue des Deux Mondes*, December 1871, also "The Friendly Societies of Antiquity," by Tompkins, *Old-fashioned Magazine*, April 1868, and the article *Curia*.

² The custom of "setting out the watch," at the "marching watch," in London, Bristol, Worcester, &c, on midsummer eve, originated in the part taken in the defence of the city by the trade guilds or companies of those places, it was a kind of "military service" (Edinb.)

(Breton). These were the small and numerous societies that sprung up all over the country in every village, in small or large towns, at different times as the need arose, or for good neighbourhood's sake. Their objects included "not only devotions and oisons, but also every exercise of Christian charity, and therefore, above all things, mutual assistance of the guild brothers in every exigency, especially in old age, in sickness, in cases of impoverishment,—if not brought on by their own folly,—and of wrongful imprisonment, in losses by fire, water, or shipwreck, aid by loans, provision of work, and lastly, the burial of the dead. It included further the assistance of the poor and sick, and the visitation and comfort of prisoners not belonging to the guild" (Brentano). These societies were composed of men and women of all ranks, and, when, as in some instances, they grew into wealth and popularity, kings and princes did not disdain to become guild-brothers. Henry IV and Henry VI were members of the guild of the Trinity at Coventry, Henry VIII and his queen were members of the guild of St Barbara, of St Katherine's church next the Tower, London. Another prince belonged to the famous guild of St George at Norwich. One guild, however, who said they were "of the rank of common and middling folks," would not admit even a mayor or a bailiff.

Each member took an oath, and paid an admission fee and yearly contribution, they held regular business meetings or "mutual speech," and had an annual "guild-day." Every guild had its livery, which the members were expected to wear at funerals, feasts, &c., and they had strict rules for good life and behaviour. The little parochial guilds met in a room or in members' houses, if the guild was rich enough it had a hall or "guild-house," legacies and gifts were made to them, and they lent out of their stock to poor members, or devoted it to some public or charitable object. Schools and churches were founded or helped by these private guilds, as some of the colleges at Cambridge, schools at Coventry, Worcester, Dayles, Sleaford, Ludlow, Bristol, and elsewhere, forty guilds of Bodmin (of which only five were craft guilds) joined in the repair of the church there. Bridges and town-walls were repaired, both in England and in France—in which latter country M. Guy finds some relics of these social guilds. The performing of miracle and other plays, setting out of pageants, and providing of minstrels were undertaken by many of the social as well as by the craft guilds, and in many towns formed an important adjunct to the municipal proceedings, as at Coventry, York, Durham, Norwich, &c., the Lord Mayor's show of London owes its origin to this custom.¹

These local social guilds were very numerous in England and in the Teutonic countries, it is believed that they were so in France, but little is known of them elsewhere. There were 50 such guilds in the county of Cambridge, 909 in Norfolk, 42 in Bodrum, 80 in Cologne, 70 at Lubek, &c.

At the time of the Reformation these guilds were abolished in Protestant countries, under pretence of their being superstitions foundations, in Denmark and North Germany their property was devoted to public service, but in England it was handed over to the king and his courtiers, their guild-halls became poor-houses, then pageants were laid aside. A very few of these societies escaped, St George's guild at Norwich continued to live on many years.

Wickliffe, in the 14th century, had complained of the abuses among the guilds, including those of trades. In 1389 returns were made into Chancery of the social and other guilds in England, these, though imperfect, give a valuable body of details, and draw the distinction between the two

great classes of social and trade guilds. The trade guilds have in all countries attracted more attention than the rest, on account of their wealth and importance, they are of two orders, *guild-merchant* and *craft-guild*. The guild-merchant arose in this way, the same men who in the growth of towns became citizens by reason of possessing town-land, frequently were also traders, the uncertain state of society in early times naturally caused them to unite for protection of their trade interests in a *guild mercatoria*, which made internal laws akin to those of other guilds, the success of these private interests enlarged their importance, and when the towns and boroughs obtained confirmation of their municipal life by charter, they took care to have it included that the men of the place should also have their guild merchant.² Thus these guilds obtained the recognition of the state, in their origin they had been as other guilds, putting especially of the character of peace-guilds, but now "the citizens and the guild became identical, and what was guild-law" often became the law of the town. In great cities, such as London and Florence, we do not hear of merchant guilds (Notion), these the separate occupations or crafts early asserted their associating power and independence, and the craft guilds gradually took a place in the organization of the town government. Many craft-guilds, the heads of which were concerned in the government of the commune, as is found in Italy between the 9th and the 12th centuries (Ferraro, *Hist. de Florence*). But in England and the north of Europe the guilds merchant during this period, having grown rich and tyrannical, excluded the landless men of the handicrafts, these then uniting among themselves, there arose everywhere by the side of the guilds merchant the craft guilds, which gained the upper hand on the Continent in the struggle for liberty in the 13th and 14th centuries. In England these companies usually existed side by side with the old town or merchant guild, until at length their increasing importance caused the decay of the old guilds, and the adoption of these crafts as part of the constitution of the towns (13th to 15th century). The separation of the richer and perhaps the older from the poorer of the companies occurred, and thus arose the paramount influence of a few,—as the twelve great Companies of London, the *Aste Mayor* of Florence, and others.

The constitution of the trade-guilds was formed on the model of other guilds, they appointed a master or alderman and other officers, made ordinances, including provisions for religious observance, mutual help, and burial, the town ordinances yet remaining of many places, as of Berwick, Southampton, and Worcester, show traces of the trade laws of the old guilds-merchant. As their principal object, "the craft-gildmen provided for the maintenance of the customs of their craft, framed further ordinances for its regulation, (including care against fraudulent workmanship), saw these ordinances properly executed, and punished the guild brothers who infringed them." "Though the craft guilds, as voluntary associations, did not need confirmation by the authorities at their birth, yet this confirmation became afterwards of the greatest importance, when the guilds wanted to be recognized as special and independent associations, which were thenceforth to regulate the trade instead of the authorities of the town" (Brentano). Hence obtained the practice of procuring a charter in confirmation and recognition of their laws, in return for which certain taxes were paid to the king or other authority. It is therefore erroneous to state, as is sometimes done, that these companies owe their origin to royal charter, or that they required a licence.

Few important towns in Great Britain have been with-

¹ Probably the numerous societies in France and Flanders of the 12th and 13th centuries for keeping the poetic and musical foundation of *La Fête de Dieu* belong to the class of social guilds. One of them was set up in London (Riley's *Life of Ousewarden*).

² There are numerous examples of this among the borough 1000's of England and Scotland.

out a more or less number of craft guilds. London, York, Exeter, Norwich, Bristol, Coventry, &c., teemed with their life and pageantry. But the Reformation shook these as it shook every other, the associations they suffered, and the altered conditions of social economy and labour have contributed to their decay, "all that remains of the ancient guilds in the lively cities of to-day is the common eating and drinking." In the centres of industry of Italy, Spain, Germany, even in Constantinople, they once formed the strength of commerce, but, abused or decayed, in France they were abolished on 14th August 1789, in Germany their last remnants died in 1869.¹ In Constantinople numerous trade guilds were flourishing up till the year of 1877-78. In Russia there are no true spontaneous guilds, the trade companies were imposed by the imperial orders of Catherine and Peter; the Great

GUILDFORD, a municipal and parliamentary borough and market-town of England, capital of the county of Surrey, is beautifully situated on a gentle acclivity of the northern chalk downs and on the river Wey, crossed there by a bridge of five arches, 30 miles S W of London. It consists chiefly of one long, wide, and well-built street, and contains a number of old picturesque gabled houses, with quaint lattices and curious doorways. The principal buildings are the ruins of an old castle, erected soon after the Norman conquest, and for a long time used as the county jail, the town-hall, erected in 1638, containing a number of interesting pictures, the corn market house, erected in 1818, the county hall and assize court in the domestic Gothic style, erected in 1862, the Abbots Hospital, founded by Archbishop Abbot for decayed tradesmen and decayed tradesmen's widows, the county hospital, opened in 1806, erected as a memorial to the Prince Consort, the Royal Free Grammar School, founded in 1500, the Institute, formed in 1844, with museum, library, and reading and lecture rooms, the church of St Mary, in the Anglo Norman style, of very early origin, and restored in 1893, the church of St Nicholas, in the Gothic style, erected on the site of an ancient structure of Saxon origin, and Holy Trinity church, a red brick structure erected 1740-63, with a square embattled tower. Guildford has corn mills, iron foundries, and breweries. There is considerable trade in corn, and fairs are held for cattle, sheep, horses, and pigs. Guildford first returned members to Parliament in the reign of Edward I. Formerly it had two members, but since the Reform Act of 1832 it returns only one. The population of the municipal and parliamentary borough in 1861, when the municipal and parliamentary limits were co-extensive, was 8020, in 1871 the population of the municipal borough (area 5343 acres) was 9106, and that of the parliamentary borough (844 acres) 9801.

It is probable that Guildford is of Roman origin, but it is first mentioned in the will of King Alfred, who bequeathed it to his nephew Ethelwald. Next it took place, in 1039, the murder of Alfred, youngest son of King Ethelred, and his Roman surname, by the monk of Evesham. It was an occasional residence of the English kings, and a town on which it remained attached to the royal demesnes until 1680, when the whole of the crown lands at Guildford were vested in Murray, earl of Annandale. After various changes they passed in 1786 to the Onslow family, with whom they still remain.

¹ There is, however, a lively movement for the revival of craft guilds in Germany at the present time (1878).

GUILLEMOT (French, *Guillemot*), the name accepted by nearly all modern authors for a Sea-bird, the *Colymbus trale* of Linnæus and the *Uria trale* of Latham, which nowadays it seems seldom if ever to be seen among those who, from their vocation, are most conversant with it, though, according to Willughby and Ray his translator, it was in their time so called "by those of Northumberland and Durham." Around the coasts of Britain it is variously known as the Frowl, Kiddy or Skiddaw, Langy (of Ice Landic, *Langya*), Lavy, Marock, Mure, Boud (*U. Goud*, vol. xi p. 341), Scutlock, Stankor, or Tinkskor, and Willock. The number of local names testifies to the abundance of this bird, at least of old time, in different places, but it should be observed that in certain districts some of them are the common property of this species and the Razor-bill. In former days the Guillemot yearly frequented the cliffs on many parts of the British coasts in countless multitudes, and this is still the case in the northern parts of the United Kingdom, but more to the southward nearly all its smaller settlements have been rendered utterly desolate by the wanton and cruel destruction of their tenants during the breeding season, and even the inhabitants of those which were more crowded had become so thinned that, but for the intervention of the Sea-birds Preservation Act (32 and 33 Vict. cap. 17), which provided under penalty for the safety of this and certain other species at the time of year when they were most exposed to danger, they would unquestionably by this time have been exterminated so far as England is concerned. The slaughter, which, before the passing of that Act, took place annually on the cliffs of the Isle of Wight, near Flamborough Head, and at such other stations frequented by this species and its allies the Razor-bill and Puffin, and the Kittiwake-Gull, as could be easily reached by excursionists from London and the large manufacturing towns, was in the highest degree brutal. No use whatever could be made of the bodies of the victims, which indeed those who indulged in their massacre were rarely at the trouble to pick out of the water, the birds shot were all engaged in breeding, and most of them had young, which of course slaved to death through the destruction of their parents, intercepted in the performance of the most sacred duty of nature, and butchered to gratify the murderous lust of those who sheltered themselves under the name of "sportsmen."

Part of the Guillemot's history is still little understood. We know that it arrives at its wonted breeding stations on its accustomed day in spring, that it remains there till towards the end of summer, its young are hatched and able, as they soon are, to encounter the perils of a seafaring life, when away go all, parents and progeny. After that time it commonly happens that a few examples are occasionally met with in bays and shallow waters. Tempestuous weather will drive ashore a large number in a state of utter destitution—many of them indeed are not unquietly washed up dead—but what becomes of the bulk of the birds, not merely the comparatively few thousands that are natives of Britain, but the tens and hundreds of thousands, not to say millions, that are in summer denizens of more northern latitudes, no one can yet say. This mystery is not peculiar to the Guillemot, but is shared by all the *Alcedo* that inhabit the Atlantic Ocean. Examples stray every season across the Bay of Biscay, are found off the coasts of Spain and Portugal, enter the Mediterranean and

² The word, however, seems to be cognate with or derived from the Welsh and Norse *Guillem*, or *Guillem* as Pennant spells it. The sea-duck may have no real meaning, but one cannot help comparing the resemblance between the French *Guillemot* and *Guillemotte* with that between the English Willock (another name for the bird, as will be seen by the text) and Willock.

reach Italian waters, or, keeping further south, may even touch the Madeira, Canaries, or Azores, but these have no proportion whatever to the mighty hosts of whom they are literally the "scouts," and whose position and movements they no more reveal than do the vedettes of a well-appointed army. The common Guillemot of both sides of the Atlantic is replaced further northward by a species with a stout bill, the *Uria* or *U. lomvia* of ornithologists, and on the west coast of North America by the *U. lomvia*. The habits of all these are essentially the same, and the structural resemblance between all of them and the Auks is so great that of late several systematists have relegated them to the genus *Auqa*, confining the genus *Uria* to the Guillemots of another group, of which the type is the *U. gypha*, the Black Guillemot of British authors, the Dovekey or Greenland Dove of sailors, the Tystie of Shetlanders. This bird assumes in summer an entirely black plumage with the exception of a white patch on each wing, while in winter it is beautifully marked with white and black. Allied to it as species or geographical races are the *U. lomvia*, *U. lomvia*, and *U. lomvia*. All these differ from the larger Guillemots by laying two or three eggs, which are generally placed in some secure niche, while the members of the other group lay but a single egg, which is invariably exposed on a bare ledge. (A.)

GUILLOTINE, the instrument for inflicting capital punishment by decapitation, introduced into France at the period of the Revolution. It consists of two upright posts surmounted by a cross beam, and grooved so as to guide an oblique-edged knife, the back of which is heavily weighted to make it fall swiftly and with force when the cord by which it is held aloft is let go. Some ascribe the invention of the machine to the Persians, and previous to the period when it obtained notoriety under its present name it had been in use in Scotland, England, and various parts of the Continent. There is still preserved in the Antiquarian Museum of Edinburgh the rude guillotine called the "maiden" by which the regent Morton was decapitated in 1581. The last persons decapitated by the Scotch "maiden" were the marquis of Argyll in 1661 and his son the earl of Argyll in 1685. It would appear that no similar machine was ever in general use in England, but until 1650 there existed in the forest of Hardwick, which was contiguous with the parish of Halifax, West Riding, Yorkshire, a mode of trial and execution called the gibbet law, by which a felon convicted of theft within the liberty was sentenced to be decapitated by a machine called the Halifax gibbet. A print of it is contained in a small book called *Halifax and its Gibbet Law* (1708), and in Gibson's edition of Camden's *Britannia* (1722). In Germany the machine was in general use during the Middle Ages, under the name of the *Dreif*, the *Hobel*, or the *Dolander*. Two old German engravings, the one by George Perner, who died in 1650, and the other by Heinrich Adlger, with the date 1553, represent the death of a son of Tiberius Marius by a similar instrument, and its employment for the execution of a Spartan is the subject of the engraving of the eighteenth symbol in the volume entitled *Symbolische Questions de Universis Generis*, by Achilles Bocchi (1555). From the 13th century it was used in Italy under the name of *Morsina*, for the execution of criminals of noble birth. The *Chronique de Jean d'Antony*, first published in 1836, gives minute details of an execution in which it was employed at Genoa in 1507, and it is elaborately described by Pons Labat in his *Voyage en Espagne et en Italie* in 1730. It is mentioned by Turgot in his *Mémoires* as in use in the south of France, and he describes the execution by it of Marshal Montmorency at Toulouse in 1632. For about a century it had, however, fallen into general disuse on the Continent, and Dr Guillotine, who first suggested its

use in modern times, is said to have obtained his information regarding it from the description of an execution that took place at Milan in 1702, contained in an anonymous work entitled *Voyage Historique et Politique du Suisse, d'Italie, et d'Allemagne*.

Guillotine, who was born at Sautes, May 28, 1738, and elected to the Constituent Assembly in 1789, brought forward on the 1st December of that year two propositions regarding capital punishment, the second of which was that, "in all cases of capital punishment it shall be of the same kind—that is, decapitation—and it shall be executed by means of a machine." The various rugged in support of this proposition were that in cases of capital punishment the privilege of execution by decapitation should no longer be confined to the nobles, and that it was desirable to render the process of execution as swift and painless as possible. The debate was brought to a sudden termination in peals of laughter caused by an indiscreet reference of Dr Guillotine to his machine, but his ideas seem gradually to have leavened the minds of the assembly, and after various debates decapitation was adopted as the method of execution in the penal code which became law on the 6th October 1791. At first it was intended that decapitation should be by the sword, but on account of a memorandum by M. Sanson, the executioner, pointing out the expense and certain other inconveniences attending that method, the assembly referred the question to a committee, at whose request Dr Antoine Louis, secretary to the academy of surgeons, prepared a memorandum on the subject. Without mentioning the name of Guillotine, it recommended the adoption of an instrument similar to that which was formerly suggested by him. The assembly decided in favour of the report, and the contract was offered to the person who usually provided the instruments of justice, but as his terms were considered exorbitant, an agreement was ultimately come to with a German of the name of Schmidt, who, under the direction of M. Louis, furnished a machine for each of the French departments. After satisfactory experiments had been made with the machine on several dead bodies in the hospital of Bicêtre, it was erected on the Place de Grève for the execution of the highwayman Pallester on the 25th April 1792. While the experiments regarding the machine were being carried on, it received the name *Louisset* or *La Petite Louisset*, but this name of the nation seems soon to have reverted to Guillotine, who first suggested its use, and in the *Journal des Révolutions de Paris* for 28th April 1792, it is mentioned as *la guillotine*, a name which it thenceforth bore both popularly and officially. In 1795 the question was much debated as to whether or not death by the guillotine was instantaneous, and in support of the negative side the case of Charlotte Corday was adduced whose contumacious, it is said, blushed as it with indignation when the executioners, holding up the head to the public gaze, struck it with his fist. The connexion of the instrument with the horrors of the Revolution has hindered its introduction into other countries, but in 1853 it was adopted under the name of *Palladium* or *Pallad* by the kingdom of Saxony, and it has been subsequently introduced into several other German states. It has often been stated that Dr Guillotine perished by the instrument which bears his name, but it is beyond question that he survived the Revolution, and died a natural death in 1814.

W. Choker in the *Quarterly Review* for December 1848, republished separately in 1880 under the title *The Guillotine, a Historical Essay*.

GUIMARÃES, a fortified city of Portugal, province of Minho, government district of Braga, is beautifully situated on the Ave, 12 miles south-east of Braga. It stands on an acclivity, and with its Moorish towers has a very picturesque appearance. An old castle which was the birthplace of

Alphonso, the first king of Portugal, is still in a state of good preservation. Among the four churches may be mentioned the *Catedral*, founded in 1386, and although modernized still retaining intact its beautiful choir. The principal manufactures are knives and other steel wares, leather, paper, and table linen. In the neighbourhood there are sulphurous springs, with a temperature of 164° Fahr., frequented since the origin of the city in the 4th century. Guimarães was made the chief town of the county of Portugal in the 11th century by Henry of Burgundy, and retained that honour till 1511, when it was conferred by King Emanuel on Lisbon. The population is about 10,000.

GUINEA, the general name applied by Europeans to part of the western coast region of intertropical Africa. Like many other geographical designations the use of which is controlled neither by natural nor political boundaries, it has been very differently employed by different writers and at different periods. In the widest acceptation of the term, the Guinea coast may be said to extend from 11° N lat. to 16° S lat., or in other words, from the neighbourhood of Cape Veriga to Cape Negro. Southern or Lower Guinea comprises the coasts of Loango, Congo, Angola, and Benigné, and Northern or Upper Guinea comprises part of Senegambia, the Sierra Leone district, the Grain Coast, the Ivory Coast, the Gold Coast, the Slave Coast, the Niger Delta, and the Calabar district. The Cameroonian mountains may be accepted as the limit of the two divisions, though some writers prefer the river Gambia or the equator. In a narrower and perhaps more common use of the name, Guinea is the coast only from Cape Palmas to the Gaboon. Originally, on the other hand, Guinea was supposed to commence as far north as Cape Nun opposite the Canary Islands, and Asuara is said to be the first authority who brings the boundary south to the Senegal. The name is derived from Guinea, Genua, or Ginnar, a town and kingdom in the Niger district, and though it appears on a map as early as 1351, it did not come into general use till the close of the 15th century. Few questions in historical geography have been more keenly discussed than that of the first discovery of Guinea by the navigators of modern Europe. It appears from the testimony of Jacopo Doria that two Genoese, Ugolino and Guido de Vivaldi, were sailing south along the African coast in 1291, but there is almost no further record of their voyage. The French claim that in the latter part of the 14th century this people of Dieppe sent out several expeditions to Guinea, and Jean de Béthencourt, who settled in the Canaries about 1402, made explorations towards the south. At length, in the latter half of the 15th century, the consecutive efforts of the navigators employed by Prince Henry of Portugal, Cadamosto, Unodunare, and Diogo Gomes, made the whole region familiar to Europeans.

See *Asiatick, Chroniques de descouvertes et conquêtes de Guinée*, published with an introduction, by Bures de Saintre, Paris, 1841; Villault de Bellefleur, *Relation des Côtes d'Afrique appelées Guinée*, Paris, 1679; *Nomenclature, Mém. d'un voyage sur le rivage de la Guinée*, 1876; *Myo, Life of Prince Henry the Navigator*, London, 1898, and the elaborate review of Major's work by M. Colman in the *Bulletin de la Société de Géographie*, 1878.

GUINEA FOWL, a well-known domestic gallinaceous bird, so called from the country whence in modern times it was brought to Europe, the *Meleagris* and *Anas* or *Gallina Numidica* of ancient authors.¹ Little is positively known of the wild stock to which we owe our tame birds, nor can

the period of its reintroduction (for there is apparently no evidence of its domestication being continuous from the time of the Romans) be assigned more than roughly to that of the African discoveries of the Portuguese. It does not seem to have been commonly known till the middle of the 16th century, when Caius sent a description and figure, with the name of *Gallus Mauritius*, to Gesner, who published both in his *Psittacologia* in 1558, and in the same year Belon also gave a notice and woodcut under the name of *Poulet de la Guinée*, but while the former authors properly referred their bird to the ancient *Meleagris*, the latter confounded the *Meleagris* and the Turkey.

The ordinary Guinea Fowl of our poultry-yards is the *Numida meleagris* of ornithologists, and is too common a bird to need description. The chief of only changes which domestication seems to have induced in its appearance are a tendency to albinism generally shown in the plumage of its lower parts, and frequently, though not always, the conversion of the colour of its legs and feet from dark greyish-brown to bright orange. That the home of this species is West Africa from the Gambia² to the Gaboon is certain, but its range in the interior is quite unknown. It appears to have been imported early into the Cape Verd Islands, where, as also in some of the Greater Antilles and in Ascension, it has run wild. Representing the species in South Africa we have the *N. coronata*, which is very numerous on the Cape Colony to Oryampoland, and the *N. ornata* of Dr. Finsch and Hantsch, which replaces it in the west as far as the Zambesi. Madagascar also has its peculiar species, distinguishable by its red crown, the *N. mistata* of Falcis, a name which has often been misapplied to the last. This bird has been introduced to Rodriguez, where it is now found wild. Abyssinia is inhabited by another species, the *N. psittacina*,³ which differs from all the foregoing by the absence of any red colouring about the head. Very different from all of them, and the finest species known, is the *N. melanura* of Zanzibar, conspicuous by the bright blue in its plumage, the hackles that adorn the lower part of its neck, and its long tail. By some writers it is thought to form a separate genus, *Acrypium*. All these Guinea Fowls are characterized by having the crown bare of feathers and elevated into a bony "helmet," but there is another group (to which the name *Guinea* has been given) in which a thick tuft of feathers ornaments the top of the head. This contains four or five species, all inhabiting some part or other of Africa, the best known being the *N. cristata* from Sierra Leone and other places on the western coast. This bird, apparently mentioned by Maragnone more than 200 years ago, but first described by Falcis, is remarkable for the structure—unique, if not possessed by its representative forms—of its *pygma*, where the head, instead of being the thin plate found in all other *Guinea*, as a hollow cup opening upwards, into which the trachea dips, and then emerges on its way to the lungs. Allied to the genus *Numida*, but readily distinguished therefrom among other characters by the possession of spurs, are two very rare forms, *Agelastes* and *Phasianus*, both from Western Africa. Of their habits nothing is known. All these birds are beautifully figured in Mr. Elliot's *Monograph of the Phasianidae*, from drawings by Mr. Wolf.

(A N)
while it was blue in the former. This would look as if the *Meleagris* had sprung from what is now called *Numida psittacina*, while the *Gallina Africana* originated in the *N. meleagris*—species which, as will be seen by the text, have a different range, and if so the fact would point to two distinct introductions—one by Greeks, the other by Latins.

¹ Specimens from the Gambia are said to be smaller, and have been described as distinct under the name of *N. senegalensis*.

² Columnelli (*De Re Rustica*, viii., cap. 2) distinguishes the *Meleagris* from the *Gallina Africana* or *Numidica*, the latter having, he says, a red wattle (*galea*), a reading obviously preferable to *galea*,

³ Mr. Darwin (*Anim. and Pl. under Domestication*, i. p. 264), gives this as the original stock of our modern domestic birds, but has in the writer ventures to think he has been misled. As before observed, it may possibly have been the true *progenitor* of the Greeks.

GUINEA-PIG See CAYV

GUINGAMP, a town of France, capital of an arrondissement in the département of Côtes-du-Nord, is situated in a large and rich valley on the right bank of the Trieux, 30 miles W N W of St Brieuc. It was formerly surrounded by walls, portions of which still exist. It has a library, a museum, a prison, and a hospital dating from the 17th century, enlarged in 1830, and having within its grounds an old oak of immense size. There are also several old buildings of interest, including the beautiful church of *Notre Dame des Bon-Secours*, portions of which date from the 13th, 14th, 15th, and 16th centuries respectively, and which has been lately restored, four pillars of the tower of the chapel of Saint Leonard, dating from the 11th century, and the Ursuline convent, dating from the 17th century, now used as a cavalry depot. The beautiful fountain in the Place de l'Étoile, constructed by Italian artists in the 15th century, was replaced in 1743 by the present structure. The town has manufactures of gingham (to which it gives the name), linen fabrics, thread, leather, and hats, and there is some trade in wine, brandy, cattle, and agricultural produce. Guingamp originally belonged to the dukes of Brittany, and was inherited from them by King Louis Philippe. The population in 1876 was 7895.

GUIPUZCOA, the smallest and most densely peopled of the three Basque provinces of Spain, is bounded on the N by the Bay of Biscay, on the W by the province of Biscay, on the S and S E by Alava and Navarre, and on the N E by the Bidassoa, which separates it from France. Its area is nearly 728 square miles, and in 1870 its estimated population was 180,743. Situated on the northern slope of the great Cantabrian chain, the province has a great variety of surface in mountain, hill, and valley, and the scenery accordingly is highly picturesque and romantic. The coast is much indented, and has numerous harbours, but none of very great importance; the chief are those of San Sebastian, Leizor, Guetaria, Deva, and Frontón. The rivers (Deva, Urola, Oria, Urumea, Bidassoa) are all short, rapid, and unnavigable. The mountains are for the most part covered with forests of oak, chestnut, or pine, holly and arbutus are also common, with furze and heath in the poorer parts. The soil in the lower valleys is generally of hard clay and unfertile, it is cultivated with great care, but the grain raised falls considerably short of what is required for home consumption. The climate though moist, is mild, pleasant, and healthy, fruit is produced in considerable quantities, especially apples for manufacture into "sarragusa" or cider. The chief wealth of the province arises from its mineral stores (iron, argentiferous lead, copper) and from its excellent fisheries, which supply the neighbouring provinces (cod, tunny, salmon, oysters). The iron, which is of excellent quality, is smelted with wood. There are also considerable manufactures of woollen and cotton fabrics, paper, and lucifer matches. The people are remarkable for their fine physique, and bold manly spirit, united with honesty, industry, energy, and enterprise. The capital of the province is San Sebastian, with a population of 17,902 in 1873. All the other towns are small, Tolosa alone having a population at all exceeding 5000. Guetaria no longer retains its former importance, Mondragon is entirely dependent on the rich iron mines in its vicinity, and Salinas, on the Deva, on its salt works. A small island in the Bidassoa, called La Isla de los Fuencabres, or l'Isle de la Conférence, is celebrated as the place where the marriage of the duke of Guenne was arranged between Louis XI and Henry IV in 1463, where Francis I the prisoner of Charles V was exchanged for his two sons in 1526, and where in 1659 "the peace of the Pyrenees" was concluded between D. Luis de Haro and Cardinal Mazzarini.

The early history of Guipuzcoa, as of the other Basque provinces, is still the subject of much learned research. Now wholly subdued by the Romans, the Celtiberi in their mountain fastnesses continued to preserve their independence after the fall of the Western Empire, until the times of the great Gothic kings, Leovigild (580) and Wamba (672-681). Nominally subject to Chlovis II. at a later period, they were prompt to avail themselves of the first opportunity to assert their full independence, then alliance with the Moors, and its results at Roncesvalles are prominent facts in medieval history. About the 11th century the inhabitants of the Basque districts emerge as organized into a somewhat fixed confederation of detached republics, owning allegiance to a viceroy in fact, but under definite constitutional guarantees (fueros). In 1202 Guipuzcoa accepted as its lord Alfonso VIII of Castile, and for many centuries it ranked as a distinct "señorio" attached to the Spanish crown. The last of its distinctive fueros was abolished in July 1876.

GUISBOROUGH, or **GUISBOROUGH**, a market-town of England, North Riding of Yorkshire, is situated in a narrow but fertile valley at the foot of the Cleveland Hills, 4 miles from the mouth of the Tees and 10 miles S E of Middlesbrough. It consists chiefly of one wide and handsome street, having many good houses. The principal buildings are the parish church, which though partly rebuilt in 1791 and thoroughly renovated in 1875, has some remains of an ancient structure, the fine grammar school, founded in 1561, the town-hall, recently much improved and enlarged, the mechanics' institute, the hospital for old men and women, and the hospital for accidents erected lately by Admiral Chaloner. The ruins of the Austin priory, founded in 1129, are beautifully situated near the eastern extremity of the town. The accumulation of rubbish has been recently removed from its foundations and floors, and a large number of interesting relics discovered. Among the historic personages who were buried within its walls was Robert the Bruce, lord of Annandale, the competitor for the throne of Scotland with John Balliol, and the grandfather of King Robert Bruce. The town within late years has been rapidly increasing, on account of the iron mines in its neighbourhood, and it has also tanneries and breweries. Alum works were established in the reign of Queen Elizabeth by Sir Thomas Chaloner, who introduced the manufacture of alum into England from Italy, but they have been long discontinued. About a mile south-east of the town there is a sulphurous spring discovered in 1822, efficacious in cutaneous, rheumatic, and bilious complaints. The population of the town in 1871 was 5205, and in 1879 about 6500.

GUISE See ROBERT GUISE. **GUISE**, a fortified town of France, département of the Aube, arrondissement of Vesvins, is situated on the left bank of the Ouse, 13 miles N W of Vesvins. It was formerly the chief town of the Thiérache, a district in the extreme north of France, bordering on Hamalt. It has an old castle dating from the 16th century, and a palatial *famille* with accommodation for 400 families. The principal industries are woollen and cotton weaving, iron and copper founding, tanning, and the manufacture of alcohol and sugar. The population in 1876 was 6242.

GUISE, HOUSE OF The House of Guise, which in the 16th century suddenly rose to an eminence unrivalled in Europe, takes title from the place noticed above. The countship of Guise, a fief under the French crown, was carried in 1333 by its holder, Marie de Blois, as her dowry to Rodolf, duke of Lorraine. In 1508 René II, the conqueror of Charles the Bold, divided his territories between his sons Antony, who became duke of Lorraine, and recovered the Germanic part, and Claude, who had the French fief, including Guise.

Claude of Lorraine thus became founder of a great and well-marked family, which occupied the place that had in the fifteenth century been held by the princes of the Lilies. Generation after generation we have a duke and a cardinal side by side, they illustrate with singular

fidely the movements of the period from its Catholic side. The first duke and cardinal belonged to the Renaissance, the second put himself into the Catholic reaction, and led the resistance to the Reformation in France, the third part showed the decay of the religious movement, and its transit into political activities, being among the most ambitious statesmen of the later years of the century, while the fourth and last put full the breadth of its helms' absolutism. The family has throughout characteristic qualities,—bravery, ambition, a certain nobleness of sentiment, in imposing presence, and winning manners, they stand between nobility and royalty,—greater than the one, sometimes even outstripping the other. They seem never to forget that in their veins runs the blood of those who were or claimed the crown of Jerusalem and Naples, of Sicily and Hungary. Claude of Lorraine, born in 1498, succeeded in 1508 to a group of lordships, which by their names testify to the high fortunes of the house. Besides Guise itself, he had Blickef, Annule, Mizey, Jouvence, Harcourt, Longueville, Boves, Nablé, Lambese, and others. In addition to these, the family gathered to itself relations with Bri, Bally, Ventadour, Aguilon, Mercœur, Joyeuse, and Nevers, a cardinal's hat, together with a group of splendid church dignities, also went with the house of Guise, the archbishopric of Rheims, the bishopric of Metz, and several other bishoprics were family benefices, which enabled younger members to take an important share in the fortunes of the family. The shield of Claude expresses the pride of the race. We find there not only the Lorraine spread eagle, the German bird, but also the quarterings of eight sovereign houses, those of the kings of Hungary, Naples, Jerusalem, and Aragon, and of the sovereign lords of Arjou, Guakeliani, Flaudois, and Bai. This young prince, who claimed so much, and did so much, who both overreached his rights as a foreign prince and took precedence of the proudest in France, attached himself closely to Francis I. He was the most brilliant among the "young men" who displayed the older wisdom of the court of Louis XII. In 1513 he married Antoinette of Bourbon, the duke of Vendôme's daughter and great-aunt of Henry IV, in 1515 he accompanied Francis to Italy, and showed the mettle of his race at Marignano, where his brother Ferry was killed. From that time he sagaciously avoided the Italian expeditions, and stayed in France, winning popularity as protector of the realm. Thus in 1521 he was on the Spanish frontier, and helped to take Puenrebui, in 1522 he opposed the English in the north, covering Paris, next, he defended Champagne from the Germans, clearing that rich district with equal glory and gain. In 1525 he avoided the expedition which ended in the disaster of Pavia, when another of his brothers, Francis, was slain, and during the captivity of Francis I at Madrid, he became virtual head of the regency under the queen, Louise of Savoy. In those dark days he enabled the ransom of the peasants of Lorraine and Swabia, which threatened all the east of France. After the king's return, Claude was made (in 1527) duke of Guise, and peer, and governor of Champagne, fresh territory and wealth were added to these honors. He had now reached his highest point, henceforth it is clear that Francis I regarded him with more jealousy than favor. His ambitious views as to the crown of the "good king René" and hopes of a revived Angevin dynasty, offended the French king, though they were only dreams of the past, for the new spirit of monarchy and national life in the 16th century made any creation of lesser kingdoms on the borderlands of France and Germany impossible. Claude was a man of haughty and narrow character, cautious and persistent, he saw his way, and walked carefully along it all his days. In an age in

which wealth was becoming the most effective of all means of power, he gathered riches in all ways, fair or foul, and though willing to spend for his own advancement, he won and deserved the character of a grasping and greedy prince. His brother John, first cardinal of Lorraine, seconded him in every way, he was as greedy as the duke, though much more open-handed. Accepting the new ideas of the time, he became a splendid Renaissance pietist, the friend of Erasmus and Rabelais, and even of Marot, while, at the same time, he too faithfully reflected the worst vices of the movement. His church preference was enormous, he shamelessly took all he could get, and his brother had the distinction of giving a bad name to a whole country; for, thanks to their rapacity, the Lorraines got that reputation for avarice and greediness which has unjustly clung to them even to our days. After 1527 the cleverness of the cardinal rather than the pudence of the duke advanced the family. Claude had twelve children, a splendid group of princely youths, who inherited the hand some features and figure of their father, with even greater abilities and a more effective ambition. Francis, the eldest of those who grew up, was born in 1519, and became the second duke, Charles, born in 1524, was the second cardinal of Lorraine, a man as intelligent and depraved as his uncle, and more vigorous and ambitious, Claude's eldest son, duke of Anjou, Louis, bishop of Beauvais and cardinal of Guise, René, marquis of Elbeuf. The daughters made brilliant matches above all, the eldest, Marie, widow of the duke of Longueville, was married in 1538 to James V of Scotland, and had a stormy career as regent to her daughter, Mary Stuart, queen of Scots.

In his later days Claude of Guise withdrew somewhat from public life, he stood aloof from the intrigues of the reign, while the cardinal attached himself to the "black court," the court of Diana of Poitiers, and promoted the interests of his nephews without stint. From this time all leanings towards either Renaissance or reform were at an end. Henceforth the Guises became the leaders of the opposition to the Huguenots, the strength and support of the new Jesuit movement, and, later, the leaders of the League. Claude of Guise died in 1550, leaving his dignities to his son Francis, "le grand Guise," who had already won great credit for bravery, and had shown that dashing contempt for all rules of military pudence which gives a captain undying popularity. The ghastly wound in the face, which his rashness won for him in 1545 at the hands of the English near Doullens, got him the name of the first "Balafre." It was the outward symbol of his devotion to his country, and greatly raised his repute among the people. He had too the essential qualities of popularity, a majestic presence, and friendly manners in camp, he was chivalrous, liberal, humane, discerning. In 1552, as lieutenant-general in the three bishoprics, he withstood at the siege of Metz the last efforts of Charles V, and saved France from a terrible invasion. Thanks to the jealousy of the Montmorencies, he was sent in 1557 to conquer Naples, and would have added another to the long roll of reputations gained by Italy, had he not been suddenly recalled to protect his country after the disaster of St Quentin. With happy boldness, instead of watching the victorious allies, he suddenly attacked and took Calais, ending the English occupation of French soil, and saving his own renown to the highest point. Then, with his brother Charles, second cardinal of Lorraine, he wielded unlimited power throughout the reign of Francis II. Under Charles IX his influence abated, and he withdrew into Alsace. On his return thence in 1562, he was, however unwillingly, for he was not inhumane, the cause of the massacre of Vassy, which began the civil wars. In the first war he won the battle of Dreux (1562), and thence passing southward besieged

the Huguenots in Orleans. There, early, in 1563, he was arrested. If he was the noblest of the Guises, his brother the cardinal was the ablest. In his earlier days the cardinal had shown some sympathy with the Reformers, in later life he vigorously repressed them, and took a leading part in the council of Trent, where he is said to have sketched the first lines of the famous League. Like all early friends of the Jesuits, he did his best for education, and imprisoned men of letters, while he cooled independent ones of thought and aimed at introducing the Inquisition. He died in 1574. His younger brother Charles, cardinal of Guise, "le cardinal des bouillies," was a grand pluralist, an every-going personage, whose quiet life was in striking contrast to the feverish energy of his brothers. René, marquis of Elbeuf, another brother, is the stem of the great house of Elbeuf, Harcourt, and Lislebonne.

Henry of Guise, eldest son of Duke Francis, born in 1550, was with his father at Orleans, and saw his death. The boy therefore began his public life with an inextinguishable hatred against Huguenots, eager to distinguish himself in civil war. With his brother Louis, second cardinal of Guise, he entered into all the intrigues of the religious question, and bitterly opposed Henry of Navarre. He was at Jarnac, and in the victory of Dormans (1575) over the German invaders, he too won the title of "le Balafre." He soon became the idol of Paris, manly, handsome, and daring; he won all hearts, and was at once a popular hero. Fortune too favored him by bringing him into contact with the wretched Henry III., and with his partly cautious brother the duke of Mayenne. In 1576 he was recognized as head of the League, supported by Philip II and the papacy. Ambitious of the crown of France, he worked subtly for it behind the screen of old Cardinal Bourbon's name. In the war of the three Henries (Henry III., Henry of Navarre, Henry of Guise) he again drove the Germans out of France, and, when invited to the capital by the "Sixteen," ruled there unopposed, the "King of Paris." Henry III., whom he had compelled to sign the Edict of Union, found his supremacy intolerable, and just before Christmas (1588), the duke and the cardinal his brother were assassinated by the royal orders.

His eldest son Charles, born in 1571, was arrested at the time of the double murder, but escaped in 1591, and was welcomed with enthusiasm by the Paris mob, which hoped he would lead the infants of Spain, and with the help of Philip II secure for himself the throne of France. But the opposition of his uncle Mayenne proved fatal to the scheme. At the end of the struggle, both he and Mayenne submitted to Henry IV., helped him to reduce the nobles in Languedoc, and received the government of Provence. In Richelieu's days he aided with the queen mother, and was compelled to withdraw in 1631 to Italy, where he died in 1640. By his wife also was a cardinal brother, the third of Guise, who ruled by abandoning the ecclesiastical state, and in marrying one of the mistresses of Henry IV.

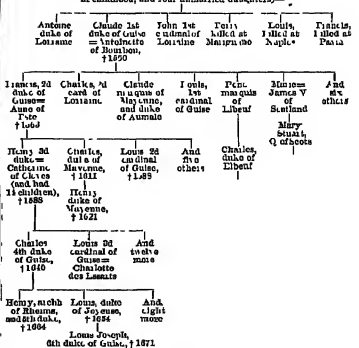

Henry, fourth son of Charles, born in 1614, had already succeeded to that family benefice, the archbishopric of Rheims, when the death of his elder brother made him head of the family, and in 1640 fifth duke. He too went against the absolutism of the age, and joined the count of Soissons. Condemned to lose his head he fled to Brussels, and took command of the Austrian troops against France, noble traitors to their country being then not uncommon. In 1613, however, after Richelieu's death, he returned to France, but being chosen their chief by the Neapolitans, at the time of Masaniello's revolt, and dazzled by this opening for his ambition, he betook himself to Naples. There his failure was complete, he was defeated and carried prisoner to Madrid. Delivered thence by the intercession of the Great Condé, he again attempted Naples,

and failed again. After this he spent the rest of his romantic life at the French court, and died in 1664 leaving no issue. His sisters were married, and of all his brothers, one only, Louis, duke of Joyeuse, left a son, born in 1650, who became sixth duke of Guise. He died of small pox in 1671, leaving an infant son, Francis Joseph, seventh duke, a sickly babe, with whom, forty years later, the direct line of the house of Guise expired. The other branches had early died out, saving the family of the seventh son of Claude fitz duke, René, marquis of Elbeuf, the marquis of Lambese, who died in 1826, was the last descendant of this branch, and with him the family finally became extinct.

The authorities for the house of Guise are Ruc. de Bouille, *Essai sur les Ducs de Guise*, 4 vols., 1863, the most complete account of the family; Vimeux, *Vie de François de Lorraine, Duc de Guise*, 1661; Guillemin, *Histoire du Cardinal de Lorraine*, the *Biographie Universelle*, art. "Guise," and Faneau's *Ducs de Guise et leur époque*, 2 vols.

Genealogical Table of the House of Guise

NOTE: If (as he united the two branches of the house of Lorraine) duke of Lorraine and Philippe of Guise, but he plus two other sons who died in childhood, and four unmarried daughters—

(G W K.)
GUITAR, a stringed instrument of Eastern origin. The name no doubt is derived from the Greek *kythara*, but the instrument itself we owe to the Arabs, who introduced it into Spain. In the 16th century it became known in Italy and France, and about 1790 a German instrument-maker of the name of Cetto greatly increased its power by adding a sixth string to the five formerly in use. The genuine Spanish guitar was introduced into England after the Peninsular War by Ferdinand Soet, a Spaniard who was both a composer for and a player on the instrument. About the same time the guitar was very much in fashion on the Continent, and even Paganini cultivated it. But this circumstance was due to the romantic associations rather than to the intrinsic merits of the instrument, and accordingly it soon relapsed into comparative oblivion. It is, however, occasionally employed in the orchestra and for the accompaniment of simple vocal pieces, and for these purposes it has no doubt its merits. The guitar is a flat-backed instrument, the sides of which turn inwards. The sound-board, pierced by a round sound-hole, is generally made of

pine, maple or cherry-wood being used for the sides and the back. The modern guitar, as already stated, has six strings, while the original *El And* of the Arabs had only four, subsequently increased to five. They are tuned to the notes E, A, D, G, B natural, and E. In the more remote keys transposition by means of a *capo tasto*, or *nut*, is effected. In this manner a basis of flat instead of natural keys may be substituted without any change of fingering. In the East, especially in Arabia, India, China, and Japan, many varieties of the guitar and its congeners are in use, the number of strings varying from two to five. For the technique of the guitar Madame Sidney Piaten's treatise, *Learning the Guitar simplified*, may be consulted.

GUIZOT, FRANÇOIS PIERRE GUILLAUME (1787-1874), historian, orator, and statesman, was born at Nîmes on the 4th October 1787, of an honourable Protestant family belonging to the *bourgeoisie* of that city. It is characteristic of the civil disabilities which still weighed upon the Protestants of France before the Revolution, that his parents, at the time of their union, could not be publicly or legally married by their own priests, and that the ceremony was clandestine. The liberal opinions of his family did not, however, save it from the sanguinary intolerance of the Reign of Terror, and on the 8th April 1794 his father perished at Nîmes upon the scaffold. Consequently the education of the future minister devolved entirely upon his mother, a woman of slight appearance and of homely manners, but endowed with great strength of character and clearness of judgment. Madame Guizot was a living type of the French Huguenots of the 16th century, stern in her principles and her faith, immovable in her convictions and her sense of duty. She formed the character of her illustrious son and shared every vicissitude of his life. In the days of his power her simple figure, always clad in deep mourning for her martyred husband, was not absent from the splendid circle of his political friends. In the days of his exile in 1848 she followed him to London, and there at a very advanced age closed her life and was buried at Kensal Green. Driven from Nîmes by the Revolution, Madame Guizot and her son repaired to Geneva, where he received his education. In spite of her decided Calvinistic opinions, the theories of Rousseau, then much in fashion, were not without their influence on Madame Guizot. She was a strong liberal, and she even adopted the notion inculcated in the *Emile* that every man ought to learn a manual trade or craft. Young Guizot was taught to be a carpenter, and he so far succeeded in his work that he made a table with his own hands, which is still preserved at Val Richer by his children. Of the progress of his various studies little is known, for in the work which he entitled *Memoirs of my own Times* Guizot omitted all personal details of his earlier life. But his literary attainments must have been precocious and considerable, for when he arrived in Paris in 1805 to pursue his studies in the faculty of laws, he entered at eighteen as tutor into the family of M. Stupfien, formerly Swiss minister in France, and he soon began to write in a journal edited by M. Suard, the *Publiciste*. This connexion introduced him to the literary society of Paris. In October 1809, being then twenty-two, he wrote a review of M. de Chateaubriand's *Martyrs*, which procured for him the approbation and cordial thanks of that eminent person, and he continued to contribute largely to the periodical press. At Suard's he had made the acquaintance of Mademoiselle de Meulan, an accomplished lady of good family, some fourteen years older than himself, who also was engaged to contribute a series of articles to Suard's journal. These contributions were interrupted by her illness, but immediately resumed and continued by an unknown hand. It was discovered

that François Guizot had quietly supplied the deficiency on her behalf. The acquaintance thus begun ripened into friendship and love, and in 1812 Mademoiselle de Meulan consented to marry her youthful ally. She was the mother of his eldest son, a young man of great promise, who died of consumption in 1837. Madame Guizot, his first wife, died in 1827, she was the authoress of many esteemed works on female education.

During this period of his life Guizot, entirely devoted to literary pursuits, published a collection of French synonyms (1809), an essay on the arts (1811), and a translation of Gibbon with additional notes in 1812. These works recommended him to the notice of M. de Fontanes, then grand-master of the university of France, and there was some question of attaching him in a subordinate office to the council of state. But on political subjects a radical antagonism existed between the young constitutional publicist and the spirit of the empire. This did not prevent M. de Fontanes from selecting Guizot for the chair of modern history in Paris in 1812. His first lecture (which is reprinted in his *Memoirs*) was delivered on the 11th December of that year. The customary compliment to the all-powerful emperor he declined to insert in it, in spite of the hints given him by his patron. He had now acquired a considerable position in the society of Paris, and the friendship of Royer-Collard and the leading members of the liberal party, including the young Duc de Broglie. Absent from Paris at the moment of the fall of Napoleon in 1814, he was at once selected, on the recommendation of Royer-Collard, to serve the Government of Louis XVIII in the capacity of secretary-general of the ministry of the interior, under the Abbé de Montesquieu. Upon the return of Napoleon from Elba he immediately resigned, on the 25th March 1815 (the statement that he retained office under General Carnot is incorrect), and returned to his literary pursuits. The liberal professions of the emperor during the Hundred Days, though backed by Benjamin Constant, did not for a moment impose on Guizot. He was convinced that Napoleon would never govern on liberal principles, and that his power could not last. He was equally convinced that a second restoration of the Bourbons was the only mode by which constitutional monarchy could be established in France. He therefore applied himself to promote that object, and repaired to Ghent, where he saw Louis XVIII, and in the name of the liberal party pointed out to his majesty that a frank adoption of a liberal policy could alone secure the duration of the restored monarchy—advice which was ill-received by M. de Blacas and the king's confidential advisers. This visit to Ghent, at the time when France was a prey to a second invasion, was made a subject of bitter reproach to Guizot in after life by his political opponents, as an unpatriotic action. "The Man of Ghent" was one of the terms of unrelentingly hurled against him in the days of his power. But the reproach appears to be wholly unfounded. The true interests of France were not in the defence of the falling empire, but in establishing a liberal policy on a monarchical basis and in combating the reactionary tendencies of the ultra-royalists. It is at any rate a remarkable circumstance that a young professor of twenty-seven, with none of the advantages of both political experience, should have been selected to convey so important a message to the ears of the king of France, and a proof, if any were wanting, that the Revolution had, as Guizot said, "done its work."

On the second restoration, Guizot resumed office as secretary-general of the ministry of justice under M. de Marbois, but this minister resigned in 1816, and the young statesman was promoted to the council of state and to the general directorship of the departmental and communal administration of the kingdom. But the reactionary spirit

of the chamber of deputies, of the royalist party, and of the successive Governments of Louis XVIII, was extremely opposed to the views of Guizot and his friends. Then it was that they endeavoured by their writings and by their speeches to apply broader principles of parliamentary government to France, and to found the party which was known by the title of the "Doctrinaires." The opinions of the doctrinaires had more of the rigour of a sect than the elasticity of a political party. Adhering to the great principles of liberty and toleration, they were sternly opposed to the anarchical traditions of the Revolution. They knew that the elements of anarchy were still fermenting in the country, those they hoped to subdue, not by reactionary measures, but by the firm application of the power of a limited constitution, based on the suffrages of the middle class and defended by the highest literary talent of the times. Their motives were honourable. Their views were philosophical. But they were opposed alike to the democratical spirit of the age, to the military traditions of the empire, and to the bigotry and absolutism of the court. The fate of such a party might be foreseen. They lived by a policy of resistance, they perished by another revolution. They are remembered more for their constant opposition to popular demands than by the services they undoubtedly rendered to the cause of temperate freedom.

In the eyes of this celebrated party, and in the sanguine spirit of the times, the French Revolution had run its course. It had exhausted the popular excesses of the convention and the military despotism of the empire. The victory of the Revolution over the arbitrary powers of the crown and the unjust privileges of the aristocracy was complete. Power was transferred to the middle classes of society, and their leaders hoped to establish on the basis of a limited suffrage all the essential rights and liberties of a free people. They hoped at the same time, by the diffusion of education amongst the people, to qualify them more and more for the exercise of these rights. They combated the reactionary and intolerant influence of the church. They opposed the high prerogative doctrines of the ministers of the crown. Their policy was described by the term "juste milieu"—a *via media* between royal authority and popular government. In those days none foresaw that they were building on the sand, and that before another generation had passed away, their scientific structure of government would crumble into ruins, and France would again traverse the dreary cycle of popular revolutions and imperial despotism. In 1821, when the reaction was at its height after the murder of the Duc de Berry, and the fall of the ministry of Duc Decazes, Guizot's relations to the Government of M. de Villele became decidedly hostile. He was deprived of all his offices, and in 1825 even his course of lectures was interdicted. During the five succeeding years he played an important part among the leaders of the liberal opposition to the Government of Charles X, although he had not yet entered parliament, and this was also the time of his greatest literary activity. Within this period he published his lectures on representative government, a work on capital punishment for political offences, a collection of memoirs of the history of England in 26 volumes, and of memoirs of the history of France in 31 volumes, and a revised translation of Shakespeare. The most remarkable work from his own pen was the first part of his *History of the English Revolution from the Accession of Charles I. to that of Charles II.*—a book of great merit and impartiality, which he resumed and completed during his exile in England after 1848. The Maslin administration restored Guizot in 1838 to his professor's chair and to the council of state. Then it was that he delivered the celebrated courses of lectures

which raised his reputation as an historian to the highest point of fame, and placed him amongst the best writers of France and of Europe. These lectures formed the basis of his general *History of Civilization in Europe*, and of his *History of Civilization in France*. Our space does not allow us to offer any remark on these well-known publications. But they must ever be regarded as classics of modern historical research, and precursors of the great advance in the treatment of modern history which has marked the last half century.

Hitherto Guizot's fame rested on his merits as a writer on public affairs, and as a lecturer on modern history. He had attained the age of forty-three before he entered upon the full display of his oratorical strength. In January 1830 he was elected for the first time by the town of Lisieux to the chamber of deputies, and he retained that seat during the whole of his political life, that is, for eighteen years. The moment was critical for a representative of liberal principles and an aspirant for power. The Polignac ministry had engaged in a mortal contest between Charles X and the national legislature, and the election of a popular man of letters by an important constituency was hailed as a triumph of the liberal cause.

Guizot immediately assumed an important position in the representative assembly, and the first speech he delivered was in defence of the celebrated address of the 21st, in answer to the menacing speech from the throne, which was followed by the dissolution of the chamber, and was the precursor of another revolution. On his returning to Paris from Nîmes on the 27th July, the fall of Charles X was already imminent. Guizot was called upon by his friends Casimir Périer, Lafitte, Villeman, and Dupin to draw up the protest of the liberal deputies against the royal ordinances of July, whilst he applied himself with them to control the revolutionary character of the late contest. Personally, Guizot was always of opinion that it was a great misfortune for the cause of parliamentary government in France that the infatuation and ineptitude of Charles X and Prince Polignac rendered a change in the hereditary line of succession inevitable. The chamber of deputies assumed the powers of a convention, and placed the duke of Orleans on the throne. A ministry was formed under M. Lafitte, and although it comprised the great names of Count Molé, Marshal Gérard, Casimir Périer, and the Duc de Broglie, the department of the interior, then the most difficult and important in the state, was allotted to Guizot. Now was his inactive administration. The waves of the great tempest which had just passed over France were to be stilled, the lives of the fallen ministers to be saved, stability to be given to the throne, confidence in the maintenance of peace to Europe, and, although the Lafitte cabinet was of short duration, these objects were attained. In 1831 Casimir Périer formed a more vigorous and compact administration, which was terminated in May 1832 by his death, the summer of that year was marked by a formidable republican rising in Paris, and it was not till the 11th October 1832 that a stable Government was formed, in which Marshal Soult was first minister, the Duc de Broglie took the foreign office, Thiers the home department, and Guizot contented himself with the department of public instruction. This ministry which lasted for nearly four years, was by far the ablest and most comprehensive that ever served Louis Philippe, it combined men of the highest talents and character, and it rendered incalculable services to the nation and the crown. Guizot, however, was already marked with the stigma of unpopularity by the more advanced liberal party. He remained unpopular all his life, "not," said he, "that I court unpopularity, but that I think nothing about it." Yet never were his great abilities more useful to his

country than whilst he filled this office of secondary rank but of primary importance in the department of public instruction. The duties it imposed on him were entirely congenial to his literary tastes, and he was master of the subjects they concerned. He applied himself in the first instance to carry a large measure for the education of the people, and to a great extent founded the existing educational establishments of the people of France. In fifteen years, under the influence of this law, the number of primary schools rose from ten to twenty-three thousand, normal schools for teachers, and a general system of inspection, were introduced, and boards of education, under mixed lay and clerical authority, were created. The second class of schools and the university of France were equally the subject of his enlightened protection and care, and a prodigious impulse was given to philosophical study and historical research. The branch of the Institute of France known as the "Académie des Sciences Morales et Politiques," which had been suppressed by Napoleon, was revived by Guizot. Some of the old members of this learned body—Talleyrand, Sismondi, Rostkowi, and Lacanau—again took their seats there, and a host of more recent celebrities were added by election for the free discussion of the great problems of political and social science. The "Société de l'Histoire de France," was founded for the publication of historical works, and a vast publication of medieval chronicles and diplomatic papers was undertaken at the expense of the state.

The object of the cabinet of October 1833 was to organize a conservative party, and to carry on a policy of resistance to the republican fiction which threatened the existence of the monarchy. It was their pride and their boast that their measures never exceeded the limits of the law, and by the exercise of legal power alone they put down an insurrection amounting to civil war in Lyons and a sanguinary revolt in Paris. The real strength of the ministry lay not in its numerical force, but in the fact that in this Government and in this alone Guizot and Thiers acted in cordial co-operation. The two great rivals in French parliamentary eloquence followed in a line the same path, but neither of them could submit to the supremacy of the other, and circumstances threw Thiers almost continuously on a course of opposition, whilst Guizot bore the greater responsibilities of power.

Once again united, in 1839, they were united, but it was in opposition to M. Molé, who had formed an intermediate Government, and this coalition between Guizot and the leaders of the left centre and the left, Thiers and Odilon Barrot, is justly regarded as one of the chief inconsistencies of his life. Victory was secured at the expense of principle, but none of the three chiefs of that alliance took ministerial office, and Guizot was not sorry to accept the post of ambassador in London, which withdrew him for a time from parliamentary contests. This was in the spring of 1840, and Thiers succeeded shortly afterwards to the ministry of foreign affairs.

Guizot was received with marked distinction by the queen and by the society of London. His literary works were highly esteemed, his character was respected, and France was never more worthily represented abroad than by one of her greatest orators. He was known to be well-versed in the history and the literature of England, and sincerely attached to the alliance of the two nations and the cause of peace. But, as he himself remarked, he was a stranger to England and a novice in diplomacy, and unhappily the embroiled state of the Syrian question, on which the French Government had separated itself from the joint policy of Europe, and possibly the absence of entire confidence between the ambassador and the minister of foreign affairs, placed him in an embarrassing and even

false position. The warnings he transmitted to Thiers were not believed. The wall-like policy of Thiers was opposed to his own conviction. The treaty of the 15th July was signed without his knowledge and executed in the teeth of his remonstrance. For some weeks Europe seemed to be on the brink of war, until the king put an end to the crisis by refusing his assent to the military preparations of Thiers, and by summoning Guizot from London to form a ministry and to aid his Majesty in what he termed "ma lutte tenace contre l'anarchie." Thus began, under dark and adverse circumstances, on the 29th October 1840, the important administration in which Guizot remained the master-spirit for nearly eight years. He himself took the office of minister for foreign affairs, to which he added some years later, on the retirement of Marshal Soult, the ostensible rank of prime minister. His first care was the maintenance of peace and the restoration of amicable relations with the other powers of Europe. If he succeeded, as he did succeed, in calming the troubled elements and healing the wounded pride of France, the result was due mainly to the indomitable courage and splendid eloquence with which he faced a raging opposition, gave unity and strength to the conservative party, who now felt that they had a great leader at their head, and appealed to the thrift and prudence of the nation, rather than to their vanity and their ambition. In his pacific task he was fortunately seconded by the formation of Sir Robert Peel's administration in England, in the autumn of 1841. Between Lord Palmerston and Guizot there existed unhappily an incompatibility of character exceedingly dangerous in the foreign ministry, of two great and in some respects rival countries. With Lord Palmerston in office, Guizot felt that he had a bitter and active antagonist in every British agent throughout the world; the combative element was strong in his own disposition, and the result was a system of perpetual conflict and counter-attacks. Lord Palmerston held (as it appeared from his own letters) that war between England and France was, sooner or later, inevitable. Guizot held that such a war would be the greatest of all calamities, and certainly never contemplated it. In Lord Aberdeen, the foreign secretary of Sir Robert Peel, Guizot found a friend and an ally perfectly congenial to himself. Their acquaintance in London had been slight, but it soon ripened into mutual regard and confidence. They were both men of high principles and honour, the Scotch Presbyterianism which had moulded the faith of Lord Aberdeen was reflected in the Huguenot ministry of France, both were men of extreme simplicity of taste, joined to the refinement of scholarship and culture, both had an intense aversion to war and felt themselves ill-qualified to carry on those adventurous operations which inflamed the imagination of their respective opponents. In the eyes of Lord Palmerston and Thiers their policy was mean and pitiful, but it was a policy which secured peace to the world, and united the two great and free nations of the West in what was termed the *entente cordiale*. Neither of them would have stooped to snatch an advantage at the expense of the other, they held the common interest of peace and friendship to be paramount, and when differences arose, as they did arise, in remote parts of the world,—in Tahiti, in Morocco, on the Gold Coast,—they were reduced by this principle to their proper insignificance. The opposition in France denounced Guizot's foreign policy as basely subservient to England. He replied in terms of unmeasured contempt,—"You may raise the pile of calumny as high as you will, vous m'arriverez jamais à l'hauteur de mon docteur!" The opposition in England attacked Lord Aberdeen with the same reproaches, but in vain. King Louis Philippe visited Windsor. The queen of England (in 1843) stayed at the

Château d'Eu. In 1845 British and French troops fought side by side for the first time in an expedition to the River Plate.

The fall of Sir Robert Peel's Government in 1846 changed these intimate relations, and the return of Lord Palmerston to the foreign office led Guizot to believe that he was again exposed to the passionate rivalry of the British cabinet. A friendly understanding had been established at Eu between the two courts with reference to the future marriage of the young queen of Spain. The language of Lord Palmerston and the conduct of Sir Henry Bulwer at Madrid led Guizot to believe that this understanding was broken, and that it was intended to place a Coburg on the throne of Spain. Determined to resist any such intrigue, Guizot and the king plunged headlong into a counter-intrigue, wholly inconsistent with their previous engagements to England, and fatal to the happiness of the queen of Spain. By their influence she was urged into a marriage with a despicable officer of the house of Bourbon, and her sister was at the same time married to the youngest son of the French king, in direct violation of Louis Philippe's promises. This transaction, although it was hailed at the time as a triumph of the policy of France, was in truth as fatal to the monarchy as it was disadvantageous to the minister. It was accomplished by a mixture of secrecy and violence. It was defended by sophistry. By the despotic and judgment of history it has been universally condemned. Its immediate object was to destroy the Anglo-French alliance, and to throw Guizot into closer relations with the reactionary policy of Metternich and the Northern court.

The history of Guizot's administration, the longest and the last which existed under the constitutional monarchy of France, bears the stamp of the great qualities and the great defects of his political character, for he was throughout the master spirit of that Government. His first object was to unite and discipline the conservative party, which had been broken up by previous discussions and ministerial changes. In this he entirely succeeded by his courage and eloquence as a parliamentary leader, and by the use of all those means of influence which France too liberally supplies to a dominant minister. No one ever doubted the purity and disinterestedness of Guizot's own conduct. He dispensed money, he lived and died poor, and though he encouraged the fever of money-getting in the French nation, his own habits retained their primitive simplicity. But he did not disdain to use in others the baser passions from which he was himself free. Some of his instruments were men, he employed them to deal with weakness after his kind. Gross abuses and breaches of trust came to light even in the ranks of the Government, and under an incorruptible minister the administration was denounced as corrupt. *Les uti alieno utio* is a proposition as false in politics as it is in divinity.

Of his parliamentary eloquence it is impossible to speak too highly. It was terse, austere, demonstrative, and commanding,—not persuasive, not humorous, seldom adorned, but condensed with the force of a supreme authority in the fewest words. He has been heard to say that he seldom had occasion to address the chambers for more than twenty minutes at a time, except when despatches were read. The consequence was that the audience hung upon his words with breathless attention. Not a syllable, not an inflexion of the voice was lost,—nothing was repeated, and when he ceased, it seemed as if the waves of an ocean had been spell-bound by his voice. He was essentially a ministerial speaker, far more powerful in defence than in opposition. Like Pitt he was the type of authority and resistance, numbed by the brilliant charges, the wit, the gaiety, the irony, and the discursive power of his great rival. Nor was he less a master of parliamentary tactics,

and of those sudden changes and movements in debate, which, as in a battle, sometimes change the fortune of the day. His confidence in himself, and in the majority of the chamber which he had moulded to his will, was unbounded, and long success and the habit of authority led him to forget that in a country like France there was a people outside the chamber elected by a small constituency, to which the minister and the king himself were held responsible.

A Government based on the principle of resistance and opposition and marked by dread and distrust of popular power, a system of diplomacy which sought to revive the traditions of the old French monarchy, a sovereign who vaguely exceeded the bounds of constitutional power, and whose obstinacy augmented with years, a minister who, though far removed from the savignty of the comital, was too obsequious to the personal influence of the king, were all singularly at variance with the promises of the Revolution of July, and they narrowed the policy of the administration. Guizot's view of politics was essentially historical and philosophical. His tastes and his acquisitions gave him little insight into the practical business of administrative government. Of finance he knew nothing, trade and commerce were strange to him, and he has been heard to express astonishment at the paramount importance Sir Robert Peel attached to his commercial policy, military and naval affairs were alien to him, all these subjects he dealt with by second hand through his friends, Darnaud, Dupleix, or Michel Bugeaud. The consequence was that few measures of practical improvement were carried by his administration. Still less did the Government lend an ear to the cry for parliamentary reform. On this subject the king's prejudices were insurmountable, and his ministers had the weakness to give way to them. Being asked after the Revolution of 1848 whether he thought the action and extra-constitutional influence of King Louis Philippe had been beneficial or injurious to the monarchy, Guizot replied that in the earlier years of the king's reign it had been of great use in strengthening the government and restoring order, but that in the later years it had been injurious to constitutional government and to the monarchy itself. It obviously drew down upon the king that responsibility which should have rested entirely on his ministers, and on the question of reform he was even more to be blamed than they were. It was impossible to defend a system which confined the suffrage to 200,000 citizens, and returned a chamber of whom half were placemen. Nothing would have been easier than to strengthen the conservative party by attacking the suffrage to the possession of land in France, but blank resistance was the sole answer of the Government to the just and moderate demands of the opposition. Warning after warning was addressed to them in vain by friends and by foes alike, and they remained profoundly unconscious of their danger till the moment when it overwhelmed them. It was the old story of a hopeless conflict between a court, obstinately addicted to an ætère theory of government, and the rising will of a nation, when a little timely and honest concession would have averted the catastrophe. Strange to say, Guizot never acknowledged either at the time or to his dying day the nature of this error, and he speaks of himself in his memoirs as the much-enduring champion of liberal government and constitutional law. He utterly fails to perceive that a more enlarged view of the liberal destiny of France and a less intense confidence in his own specific theory might have preserved the constitutional monarchy and averted a vast series of calamities, which were in the end fatal to every principle he most cherished. But with the stubborn conviction of absolute truth he diametrically adhered to his own doctrines to the end. The last scene of his political life was singularly characteristic

of his unshakable adherence to a lost cause. In the afternoon of February 23, 1818, the king summoned his minister from the chamber, which was then sitting, and informed him that the aspect of Paris and the country during the banquet agitation for reform, and the alarm and division of opinion in the royal family, led him to doubt whether he could retain his ministry. That doubt, replied Guizot, is decisive of the question, and instantly resigned, returning to the chamber only to announce that the administration was at an end, and that Mole had been sent for by the king. Mole failed in the attempt to form a Government, and between midnight and one in the morning Guizot, who had according to his custom retired early to rest, was again sent for to the Tuileries. The king asked his advice. "We are no longer the ministers of your Majesty," replied Guizot, "it rests with others to decide on the course to be pursued. But one thing appears to be evident, this state of things must be put down, these barricades must be taken, and for this purpose my opinion is that Marshal Bugeaud should be invested with full power, and ordered to take the necessary military measures, and as your Majesty has at this moment no minister, I am ready to draw up and countersign such an order." The marshal, who was present, undertook the task, saying, "I have never been beaten yet, and I shall not begin to now." The barricades shall be carried before dawn." After this display of energy the king hesitated, and soon added "I ought to tell you that M. Thiers and his friends are in the next room forming a Government!" Upon this Guizot rejoined, "Then it rests with them to do what they think fit," and left the palace. Thiers and Barrot decided to withdraw the troops. The king and Guizot next met at Claremont. This was the most perilous conjuncture of Guizot's life, but fortunately he found a safe refuge in Paris for some days in the lodging of a humble miniature painter whom he had befriended, and shortly afterwards effected his escape across the Belgian frontier and thence to London, where he arrived on the 3d March. His mother and daughters had preceded him, and he was speedily installed in a modest habitation in Pelham Crescent, Brompton.

The society of England, though many persons disapproved of nuclei of his recent policy, received the fallen statesman with as much distinction and respect as they had shown eight years before to the king's ambassador. Sums of money were placed at his disposal, which he declined. A professorship at Oxford was spoken of, which he was unable to accept. His old friends resumed their relations with him. For himself, serene and undisturbed by a catastrophe which had shaken Europe, he immediately collected a few books and resumed the narrative of the British common wealth, until he brought it down to Monk and Richard Cromwell.

Guizot survived the fall of the monarchy and the government he had served twenty-six years. He passed abruptly from the condition of one of the most powerful and active statesmen in Europe to the condition of a philosophical and patriotic spectator of human affairs. He was aware that the link between himself and public life was broken for ever, and he never made the slightest attempt to renew it. He was of no party, a member of no political body, no victim of disappointed ambition, no language of despair, even passed his life, it seemed as if the fever of oratorical debate and ministerial power had passed from him and left him a greater man than he had been before, in the pursuit of letters, in the conversation of his friends, and as head of the patriarchal circle of those he loved. The greater part of the year he spent at his residence at Val Richer, an Augustinian monastery near Lisieux in Normandy, which had been sold at the time of the first

Revolution. His two daughters, who married two descendants of the illustrious Dutch family of De Witt, so congenial in faith and manners to the Huguenots, of France, kept his house. One of his sons-in-law farmed the estate. And here Guizot devoted his later years with undiminished energy to literary labour, which was in fact his chief means of subsistence. Proud, independent, simple, and contented he remained to the last, and these years of retirement were perhaps the happiest and most serene portion of his life.

Two institutions may be here even under the second empire to have retained their freedom—the Institute of France and the Protestant Consistory. In both of these Guizot continued to the last to take an active part. He was a member of three of the five academies into which the Institute of France is divided. The Academy of Moral and Political Science owed its restoration to him, and he became in 1832 one of its first associates. The Academy of Inscriptions and Belles Lettres elected him in 1833 as the successor to M. Dacier, and in 1836 he was chosen a member of the French Academy, the highest literary distinction of the country. In these learned bodies Guizot continued for nearly forty years to take a lively interest and to exercise a powerful influence. He was the jealous champion of their independence. His voice had the greatest weight in the choice of new candidates, the younger generation of French writers never looked in vain to him for encouragement, and his constant aim was to maintain the dignity and purity of the profession of letters.

In the consistory of the Protestant church in Paris Guizot exercised a similar influence. His early education and his experience of life conspired to strengthen the convictions of a religious temperament. He remained through life a firm believer in the truths of revelation, and a volume of *Meditations on the Christian Religion* was one of his latest works. But though he adhered inflexibly to the church of his fathers and combated the rationalist tendencies of the age, which seemed to threaten it with destruction, he retained not a tinge of the intolerance or asperity of the Calvinistic creed. He respected in the Church of Rome the faith of the majority of his countrymen, and the writings of the great Catholic prelates, Bossuet and Bonald, were as familiar and as dear to him as those of his own persuasion, and were commonly used by him in the daily exercises of family worship.

In these literary pursuits and in the retirement of Val Richer years passed smoothly and rapidly away, and as his grandchildren grew up around him, he began to direct their attention to the history of their country. From these lessons sprang his last and not his least work, the *Histoire de France racontée à mes petits enfants*, for although this publication assumed a popular form, it is not less complete and profound than it is simple and attractive. The work extends to five large volumes, and has been brought down to the present time by his accomplished daughter, Madame Guizot de Witt, from her father's notes.

Down to the summer of 1874 Guizot's mental vigour and activity were unimpaired. His frame, temperate in all things, was blessed with a singular immunity from infirmity and disease, but in the month of September of that year the vital power ebbed away, and he passed quietly, content now and then a verse of Corneille or a text of Scripture, into his rest.

Public life, ambition, the love of power, and the triumph of debate no doubt shook and agitated his career, and sometimes misdirected it, but they produced no effect upon the solid structure of his character, which remained throughout perfectly simple, indifferent to wealth, and prouder of its own integrity than of all the honour the world could bestow. M. Guizot will be remembered in history less by

what he did as a politician than by what he wrote as a man of letters, and by what he was as a man, and in those respects he takes rank amongst the most illustrious representative of his nation and his age. (H R.)

(GUJARAT) See GUZERAH

GUJRANWALA, a British district in the Punjab, lying between 31° 32' and 32° 33' N lat., and between 73° 11' 30" and 74° 28' 15" E long., with an area (1877) of 2563 square miles, and population (1868) of 550,676. It is bounded on the N.W. by the river Chenab, on the S and S.E. by the districts of Jhang and Lahore, and on the E. by the district of Salukot. This district forms the central portion of the Rechna Doab, intermediate between the little submontane plains of Salukot and the desert expanses of Jhang. On the northern frontier, a belt of alluvial land, some 2 to 6 miles in breadth, fringes the Chenab through out its course. The southern portion of the plateau has a rich soil, with accessible water, the villages here lie close together, while the people are careful and industrious cultivators. But farther south the ground becomes harder and drier until in the extreme south the *dob*, a flat expanse of barren land, passes slowly into the desert of Jhang. In the south-east corner of the district, the little river Degh irrigates and fertilizes a tiny valley of its own. Two or three minor watercourses are used for the purposes of irrigation in the villages through which they pass. The country is very bare of trees, and the scenery throughout is tame and in the central plateau becomes very monotonous.

The district of Gujranwala is essentially a modern one, yet it can claim considerable relics of the past, constructed during an early period of prosperity. It seems likely that the district once contained the capital of the Punjab, at an epoch when Lahore had not begun to exist. We learn from the Chinese Buddhist pilgrim, Hsuen Tsang, that about the year 630 he visited a town known as Tsi-ka (or Tiki), the metropolis of the whole country of the five rivers. A mound near the modern village of Anamur has been identified as the site of the ancient capital. Until the Mahometan invasions little is known of Gujranwala except that Taki had fallen into oblivion and Lahore had become the chief city. Under Mahometan rule the district flourished for a time, but a mysterious depopulation fell upon the tract, and the whole region seems to have been almost entirely abandoned. At the first beginning of the Sikh war, the waste plains of Gujranwala were seized by various military adventurers. Chant Singh took possession of the village of Gujranwala, and here his grandson the great maharaja Ranjit Singh was born. The Sikh rule, which was otherwise so disastrous, appears to have been an unmitigated benefit to this district. Ranjit Singh settled large colonies in the various villages, and encouraged cultivation throughout the depopulated plain. In 1847 the district came under British influence, in connexion with the regency at Lahore, and in 1849 it was included in the territory annexed after the second Sikh war. Since that time Gujranwala has enjoyed an immunity from the catastrophes of history, with the exception of the events of 1857, which belong to the general annals of India.

The population in 1868 numbered 550,676 persons, — 306,296 males and 244,380 females. In religion, the district is mainly Mahometan. There are five towns, namely, Gujranwala, Wasirabad, Ramnagar, Bannabal, and Akalgarh, with a population aggregating 54,498 persons. The total cultivated area of the district amounts to 567,849 acres, while the cultivable margin reaches the high figure of 701,761 acres. The staple crop is wheat, which occupies one-third of the cultivated area. The other products are — barley, gram, tobacco, oil seeds, vegetables, rice, Indian corn, pulses, cotton, and sugarcane. Irrigation is very general, 827,882 acres being artificially watered. The trade of the district is unimportant. The chief exports are agricultural produce, horse vessels, leather, betel nuts, and timber. The imports consist of salt, iron, cattle, spices, and English piece-goods. A great religious fair is held at Dhonkal,

The principal channel of communication is the Northern State Railway from Lahore to Peshawar. The Grand Trunk road, connecting the same two places, traverses the district for 12 miles. There are 1025 miles of unimproved road in Gujranwala, besides a number of local by ways. The Chenab is navigable throughout for the boats of the country. The revenue in 1871 was £23,660. In 1872-73 the district contained 12 civil and 19 magisterial courts. The total police force numbered 538 men, supplemented by 1092 village watchmen. Education is still very backward, the pupils in 1873 numbered in all 5818, maintained at a cost of £2169. The mean monthly temperature in 1867 ranged from 53° in January to 82° in June. The average rainfall for the eleven years ending 1867 was 24 inches. The principal diseases are malaria, intermittent fever, and small pox. The death rate in 1872 amounted to 14,692, on 28 per thousand of the population.

GUJRANWALA, the chief town and administrative head-quarters of the above district, in 32° 9' 30" N lat. and 74° 14' E long., with a population in 1868 of 19,381. The town is situated on the Grand Trunk road and Northern State Railway, 40 miles north of Lahore. It is of modern creation, and owes its importance to the father and grandfather of Maharaja Ranjit Singh, whose capital it formed during the early period of the Sikh power. There is a mausoleum to Mahan Singh, father of Ranjit Singh, and a lofty cupola covers a portion of the ashes of the maharaja himself. The civil station has a mile south-east of the main town. It contains the court-house, treasury, jail, dispensary, post-office, staging bungalow, and church.

GUJRAT, or **GOOJRAH**, a British district in the Punjab, lying between 32° 10' 30" and 33° N lat., and between 73° 20' and 74° 51' E long., area (1877), 2020 square miles, population (1868), 616,347 souls. It is bounded on the N.E. by the native state of Kashmir, on the N.W. by the river Jhelum, on the W. by Shahpur district, and on the S.E. by the rivers Tawi and Chenab. The district of Gujrat comprises a narrow wedge of sub-Himalayan plain country, possessing few natural advantages. From the base of the Chenab on the south, the general level rises rapidly towards the interior, which, owing to the great distance of the water beneath the surface, assumes a dreary and desert aspect. A range of low hills, known as the Pabbi, traverses the northern angle of Gujrat. They are composed of a friable Tertiary sandstone and conglomerate, totally destitute of vegetation, and presenting to the view a mere barren chaos of naked rock, deeply scored with precipitous ravines. Immediately below the Pabbi stretches a high plateau, terminating abruptly in a precipitous bluff some 200 feet in height. At the foot of this plateau is a plain, which forms the actual valley of the Chenab and participates in the irrigation from the river bed. The district as a whole is well wooded, and great attention has been paid to arboriculture.

Numerous relics of antiquity stand the surface of Gujrat district. Mounds of ancient construction yield numbers of early coins, and bricks are found whose size and type prove them to belong to the prehistoric period of Hindu architecture. A mound now occupied by the village of Mogra or Mong has been identified as the site of Nicaea, the city built by Alexander the Great on the field of his victory over Porus. The Delhi empire established its authority in this district under Bahadur Lodi (1450-1488). A century later it was visited by Akbar, who founded Gujrat as the seat of government. During the decay of the Mughal power, the Ghakkars of Rawal Pindi overran this portion of the Punjab and established themselves in Gujrat about 1741. Meanwhile the Sikh power had been asserting itself in the eastern Punjab, and in 1768 the Ghakkhar chief was defeated by Sardar Gidjar Singh, chief of the Bhagat confederacy. On his death, his son succeeded him, but after a few months' warfare, in 1798, he submitted himself as vassal to the maharaja Ranjit Singh. In 1846 Gujrat first came under the supervision of British officials. Two years

later the district became the theatre for the important engagements which decided the event of the second Sikh war. After several bloody battles in which the British were unsuccessful, the Sikh power was irretrievably broken at the engagement which took place at Gujrat on the 23d of February 1849. The Punjab lay at the feet of the conquerors, and passed by annexation under British rule.

The census of 1868 disclosed a population of 616,347 persons,—871,919 males, and 244,128 females,—of whom 537,696 were Mahomedans, 78,174 Hindus, and 29,653 Sikhs. In 1874-75 the district contained four municipal towns with a population exceeding 5000—Gujrat, 17,361, Jalandhar, 14,022, Kunjib, 5361, and Dunge, 6077. While forming the staple product of the district, while bulley, grain, rice, pulses, oil seeds, cotton, etc., are of considerable value. On the Punjab side, under cultivation, 267,808 acres are provided with artificial irrigation. The chief exports are grain, raw wool, and other agricultural produce. The imports come chiefly from Fuzeh, Amritsar, Jammu, and Pind Doolab. The Northern British Railway passes through the district from south east to north west, and affords a new outlet for trade. Good branch lines of road connect Gujrat with all surrounding centers. The revenue in 1875-76 was £45,425. In the same year there were 11 civil and 10 revenue judges. The police force (1875-76) numbered 514 men, supplemented by a body of 620 village watchmen. The number of state-supported schools amounted to 17 in 1875-76, having a joint roll of 4000 pupils. The cost of education is returned at £4163. The district school at Gujrat ranks is one of the eight "higher class" schools of the Punjab. Gujrat has the reputation of being a healthy district, and, for that, and was occasionally visited. The death rate in 1875-76 was 175 per cent of the population. The district contains of charitable dispensaries, giving relief in 1875 to 81,788 persons. The annual average rainfall during night, varying 1874-75 was 28.5 inches. The fall is regular, and the district on the whole does not suffer much from drought.

Gujrat, the chief town and administrative headquarters of the above district, in 32° 34' 30" N lat. and 74° 7' 15" E long., with a population of 17,391, stands upon an ancient site, formerly occupied, according to tradition, by two successive cities, the second of which is supposed to have been destroyed in 1303, the year of an early Moghul invasion of Delhi. Nearly 200 years later Sher Shah turned his attention to the surrounding country, and either he or Akbar founded the existing town. Though standing in the midst of a flat neighbourhood, the fort was first garrisoned by Gujars, and took the name of Gujrat Akbarabad. The town was rendered memorable during the second Sikh war by the battle which takes its name from this site, and which decided the fate of the campaign, bringing the whole Punjab at once under British rule. Akbar's fort, largely improved by Gajai Singh, stands in the centre of the town. The civil station lies to the north of the native city, and contains the court-house, treasury, jail, dispensary, police lines, staging bungalow, and post-office. The trade of Gujrat is considerable.

GULL STREAM. See ATLANTIC

GULL (Wobler, *Gygis*, French, *Golland*, the name commonly adopted, to the almost exclusive exclusion of the old English name [Islandic, *Mjafir*, Danish, *Maaque*, Swedish, *Mäse*, German, *Mee*, Dutch, *Meeus*, French, *Mouette*], for a group of Sea-birds widely and commonly known, all belonging to the genus *Larus* of Linnaeus, which subsequent systematists have broken up in a very arbitrary and often absurd fashion. The Family *Laridae* is composed of two chief groups, *Larini* and *Stenonini*—the Gulls and the Terns, though two other Subfamilies are frequently counted, the Skuas (*Stenocorvinæ*), and that formed by the single genus *Icthyophaga*, the Skimmers, but there seems no strong reason why the former should not be referred to the *Larini*, and the latter to the *Stenonini*.

Taking the Gulls in their restricted sense, Mr Howard Saunders, who has lately subjected the group to a rigorous revision (*Proc. Zool. Society*, 1878, pp. 155-211), admits forty-nine species of them, which he places in five genera instead of the many which some prior investigators had sought to establish. Of the genera recognized by him,

Pagophila and *Rhodostethia* have but one species each, *Larus* and *Xema* two, while the rest belong to *Larus*. The *Pagophila* is the so-called Ivory-Gull, *P. eburnea*, names which hardly do justice to the extreme whiteness of its plumage, to which its jet-black legs offer a strong contrast. The young, however, are spotted with black. An inhabitant of the most northern seas, examples, most commonly young birds of the year, find their way in winter to more temperate shores. Its breeding-place has seldom been discovered, and the first of its eggs ever seen by ornithologists was brought home by Sir L. M'Chintock in 1853 from Cape Kinabie (*Journal of the Dublin Society*, p. 60, pl. 1), others were subsequently obtained by Dr. Macgillivray in Spitzbergen. Of the species of *Rhus*, one is the abundant and well-known Kittiwake, *R. tridactyla*, of circumpolar range, breeding, however, also in comparatively low latitudes, as on the coasts of Britain, and in winter frequenting southern waters. The other is *R. brevirostris*, limited to the North Pacific, between Alaska and Kamchatka. The singular fact requires to be noticed that in both these species the hind toe is generally deficient, but that examples of each are occasionally found in which this functionless member has not wholly disappeared. We have then the genus *Larus*, which ornithologists have hitherto attempted most unsuccessfully to subdivide. It contains the largest as well as the smallest of Gulls. In some species the adults assume a dark coloured head, even breeding season, in others any trace of dark colour is the mark of immaturity. The larger species prey chiefly on other kinds of birds, while the smaller content themselves with a diet of insects and worms. But however diverse be the appearance, structure, or habits of the extremities of the series of species, they are so closely connected by intermediate forms that it is hard to find a gap between them that would justify a generic division. Of the forty-three species of this genus recognized by Mr Saunders it would be impossible within the limits of this article to attempt to point out the peculiarities. About fifteen belong to Europe and fourteen to North America, of which (excluding stragglers) some five only are common to both countries. Our knowledge of the geographical distribution of several of them is still incomplete. Some have a very wide range, others very much the reverse, as witness *L. fuliginosus*, believed to be confined to the Galapagos, and *L. scopulinus* and *L. bulleri* to New Zealand,—the last indeed perhaps only to the South Island. The largest species of the group are the Glaucous and Greater Black-backed Gulls, *L. glauco* and *L. marinus*, of which the former is circumpolar, and the latter nearly so,—not being hitherto found between Labrador and Japan. The smallest species is the European *L. minutus*, though the North-American *L. phalaropus* does not much exceed it in size. Many of the Gulls congregate in vast numbers to breed, whether on rocky cliffs of the sea-coast, or on heathy islands in inland waters. Some of the settlements of the Black-headed or "Pewee" Gull, *L. richardsoni*, are a source of no small profit to their proprietors,—the eggs, which are rightly accounted a great delicacy, being taken on an orderly system up to a certain day, and the birds carefully protected. Those of the Roseate Gull, *Rhodostethia rosea*, forms a well-marked genus, distinguished not so much by the pink tint of its plumage (for that is found in other species) but by its small Dove-like bill and wedge-shaped tail. It is an exceedingly scarce bird, little more than a dozen examples being known to exist in collections. Beyond its having an Arctic habitat, little has yet been ascertained about it. More rare still is one of the species of *Xema*, *X. fuscescens*, of which only two specimens have hitherto been found to have come from the Galapagos, have been seen. Its smaller congener Sabine's Gull, *X. sabini*, is more common, and has been found breeding both in Arctic America and

GUMRI, or as it is now more frequently called **ALVANATSEH**, in honour of the empress Alexandra, a town of Russian Armenia in the province of Eivan, on the old frontier of the Turkish territory which was formed by the river Arpachai. It is situated at a height of 5268 (according to Abich, 4819) feet above the sea, on an eminence which commands the environs but is somewhat defective in a military point of view because the neighbouring valleys form a kind of screened approaches. The fortifications, erected in 1837 by command of Nicholas I., are the strongest in that part of Asia with the exception of those of Kars, and would be quite impregnable to an Eastern army. Like the ordinary houses of the town, they are built of limestone, and they consist of regular bastions cased and mounted with guns and surrounded with a ditch. There are several handsome Armenian churches in Gumri, one of the finest of which was built in 1873. The town passed to Russia by the peace of Adrianople. In 1840 it was made a district town of the Gruzian Imperial government, and in 1850 it was incorporated with the Eivan government. In 1832 it contained only about 60 houses, but they had increased to 1200 in 1838. At present its population is about 16,000.

GUM-TREE See **EUCALYPTUS**.

GUN-COTTON (*Pyrocellulose*, *Coton poudre*, *Fulmin cotton*, *Schoenbaumwolle*). In 1838 Pérouze observed that when cotton fibres or ropes were immersed in cold concentrated nitric acid for a short time the free acid being subsequently removed by washing, these materials became, without important alteration of structure, converted into substances possessed of explosive properties. These were at the time accepted as closely allied to the substance named *xylocetin*, described some years previously by Braconnet, which is obtained by adding water to a solution of starch in cold nitric acid. But subsequent observation established the identity of these explosive products with the explosive cotton, or gun cotton, of which in 1845 Schonbein announced the discovery, and which he at once proposed as a substitute for gunpowder. Soon after this announcement Bottger and Otto published the method of producing gun-cotton by immersing carded cotton in cold concentrated nitric acid, and subsequently Knop introduced the more advantageous method of treating the cotton wool with a mixture of nitric and sulphuric acids, the latter being used as a dehydrator of the nitric acid, and as an absorbent of the water eliminated by the nitrification of the cellulose or cotton fibre. The composition of gun cotton was subsequently made the subject of study by Bottger, Pérouze, Pélitot, Von Kitchhoff, Sobiero, Béchamp, Foret, Cum, Gladstone, Hadow, and others, and various formulae were proposed as representing its composition. The divergence of opinion on this point arose partly from difficulties attending the preparation of uniform products, and the obtaining of trustworthy analytical results with these, and partly from differences of opinion regarding the nature of the chemical reaction, whereby the cellulose becomes converted into an explosive body. The products obtained in the earlier investigations differed very much as regards their solubility in mixtures of alcohol and ether, and also with respect to the proportion which their weight bore to that of the cotton wool employed in the experimental operations. Cum was the first to entertain the view that gun-cotton might be regarded as cellulose, in which the two or three atoms of hydrogen are replaced by their equivalent of nitric peroxide. This view was afterwards also advanced by Gerhardt, and it received strong support from the researches of Hadow, whose results established the fact that several distinct varieties of pyrocellin could be produced by varying the proportions of nitric and sulphuric acids used, and who definitely established the composition of three of these, the

most explosive of which constituted the chief proportion of the product originally obtained as gun cotton, and had the composition expressed by the name trinitrocellulose. This highest nitro-product in its pure state is insoluble in mixtures of ether and alcohol, whereas the lower products (one of which is the so-called *collodion gun cotton*, used for photographic purposes, see **COLLODION**, vol. vi. p. 149) differed in regard to their ready solubility in different mixtures of those solvents. Crum's formula for pyrocellin, thus confirmed by Hadow, was afterwards strongly supported by Schötte, Redtenbacher, and Schneidel, in their joint investigation of gun-cotton manufactured in Austria by the improved process of Von Lenk, and though again disputed by Pérouze and Many, and by Clapmont and Pellé, the correctness of the formula $C_{12}H_7N_3O_{11}$ (or $C_6H_3N_3O_5$), originally proposed by Cum, was conclusively established in 1866 by the exhaustive analytical and synthetical experiments of Abel. In the manufacture of gun-cotton, even when most carefully conducted, the most explosive product, trinitrocellulose, is never obtained in a condition even approaching purity, it always contains an admixture (ranging from 4 to 10 per cent in the products of highest quality) of the lower nitrocellulose products, *i.e.*, the soluble varieties of gun cotton. In addition to these impurities it contains, even when the cotton employed has been submitted to purification by treatment with alkali, small proportions of nitrogenous matters, soluble in alcohol, formed from resins or fatty substances retained within the cotton fibre. These substances are very much more prone to undergo decomposition (with development of nitrogen acids) by exposure to heat or light than the cellulose derivatives themselves, and Abel's experiments demonstrated that the uncertain stability of gun-cotton, which brought this material into bad repute not long after its discovery, from the occurrence of disastrous explosions arising apparently from its spontaneous decomposition, was ascribable primarily to the development of free acid in the gun-cotton by the action of comparatively moderate heat or of light upon these impurities.

The occurrence of a violent explosion at the works of Messrs Hall of Faversham, not long after they had commenced the manufacture of Schonbein's gun-cotton wool, followed by a similar casualty in France, led to the abandonment of endeavours to apply this substance, within a brief period of its discovery, except in Austria, where Von Lenk persevered in attempts to devise means for obtaining it in a pure and therefore more stable condition, as well as for bringing its explosive action sufficiently under control to permit of its advantageous employment as a substitute for gunpowder, not only for destructive but also for projectile purposes. The system of manufacture elaborated by Von Lenk consisted in loosely spinning long staple cotton into yarn of various sizes and different compactness, this yarn was converted into gun-cotton by very careful treatment with a large excess of the strongest nitric and sulphuric acids, the product being immersed for many weeks in running water, and then treated with weak alkali, the gun-cotton yarn and thread were either wound more or less compactly on reels or cores, for employment in firearms, or made up into very compact ropes with hollow cores, or into plates, of lamp-work form, for employment in shells or mines. The rapidity of explosion of the gun-cotton, *in open air*, or under slight confinement, was thus brought to a great extent under control, but if the resistance opposed to the expansion of the highly heated gases, upon the first ignition of the confined gun cotton developed sufficient pressure to cause them at once to penetrate the inner structure of gun-cotton fibre which composed a charge, a sudden and violent explosion was thus brought about. Hence no practical advance was made in the reduction of the violence

of action of gun-cotton by Von Lenk's researches. By the system which Abel has more recently elaborated the fibre after its conversion into gun-cotton is reduced to a very fine state of division, when in this condition the explosive substance is readily converted into sheets or granules, or by compaction into homogeneous masses of various degrees of compactness, and of any desired form. In this manner the rapidity of action of explosion of gun-cotton may be reduced to a minimum, though uniformity of action in fire arms is still very difficult to attain with it. As the reduction of the gun cotton fibre to a very fine state of division greatly facilitates the removal by washing, and by alkaline treatment, of the small quantities of unstable impurities already spoken of, the stability of gun cotton as now manufactured is much greater than that of former products. Compressed gun-cotton needs, like the other forms in which this explosive has been used, very strong confinement for the development of violent explosion, but this can be readily accomplished without any confinement of the substance, though the agency of an initiative detonation, the explosion of 2 grains of strongly confined mercuric fulminate in close contact with the compressed material suffices to ensure this result (see *Detonation*, article *EXPLOSIVES*, vol viii p 809). Gun cotton contains in the normal (an dry) condition 2 per cent of water. The compressed material of the ordinary density (= about 1) contains from 25 to 30 per cent of water when saturated, even with 16 per cent it is unflammable, and when containing 17–30 per cent it may be cut and drilled with perfect safety. If gun cotton contains more than the normal 2 per cent of water it can no longer be detonated by the minimum quantity of fulminate, and the strength of the initiative detonation has to be increased in proportion to the amount of water it contains, when it contains 17 per cent of water, its detonation cannot be accomplished with less than 200 grains of confined fulminate. An initiative charge of 1 ounce of an dry gun cotton (detonated by means of an ordinary fulminate fuse) suffices, however, to ensure the detonation of wet gun-cotton (as used in mines, torpedoes, rockets, &c.). The susceptibility of gun-cotton to detonation when wet (and therefore perfectly unflammable) gives this substance a great advantage over other explosive agents, as it may be stored in a perfectly harmless condition (wet gun-cotton being quite unalterable) and at once used in that state as a powerful destructive agent through the agency of a detonating charge. The explosive action of wet gun-cotton is somewhat sharper than that of the dry material, the detonation being transmitted through its mass with greater

rapidity in consequence of the displacement of air in its pores by the incompressible liquid. Gun cotton, if it consists entirely of tannicocellulose, does not contain sufficient oxygen for the complete oxidation of its carbon, hence more work can be accomplished with a given weight of gun cotton if a solid oxidizing agent (a nitrate or a chlorate) be incorporated with it in proportion sufficient for complete oxidation. The compressed preparations (chlorated or nitrated gun cotton) are as sensitive to detonation as gun-cotton itself, but are less sudden or sharp in their action. These preparations, first manufactured by Abel, were extensively experimented with some years ago, and one of them, prepared with barium nitrate, is now manufactured under the name of *tonite* for blasting purposes. Preparations added to gun cotton, in the production of which wood-fibre is used as the starting point, are manufactured for sporting and blasting purposes under the name of *Schulze's powder*, sawdust powder, and patent gunpowder (b A A).

GUNDULITSCH, IVAN (1588–1638), called GIOVANNI GONDOLA, one of the most celebrated Dalmatian poets, was born August 8, 1588, at Ragusa. His early education was superintended by two Jesuits, S. Muzi and Il. Riccio, the latter of whom instructed him in philosophy. At the age of twenty Gundulitsch applied himself to the study of jurisprudence, and three years afterwards he was entrusted with a high official post, the Ragusan apud. Further particulars of his life are not known, he died December 8, 1638. Among his numerous poems the greatest is an epic entitled *Osman u dvadeset plemjah* (Osman in twenty cantos), printed for the first time at Ragusa in 1826, and republished at Agium in 1854, with a biographical sketch of the author by A. T. It was written to celebrate the victory of the Poles over the Turks and Tartars in the campaign of 1621. Cantos 14 and 15 are lost, having been suppressed by the Government of Ragusa on account of their writer's animosity against the Turks, but in their place others have been added by F. Sargo. An Italian version of this poem appeared in 1837. Of Gundulitsch's other poems, the *Hymn on the Greatness of God* and the *Tears of the Afflicted Son*, and his dramas the *Rape of Proserpine* and the *Sacrifice of Love*, deserve notice. He also made several metrical translations from the Italian poets. Gundulitsch's poems, besides their literary value, are especially interesting to a student of history, as they give a faithful picture of the time in which they were composed. A complete edition of his works, edited by V. Babulich, was published by the Illyrian university in 2 vols. Agium, 1847.

GUNDWANA, a form of the name GONDWANA (q v).

GUN MAKING

UNDER this head falls the manufacture of every description of firearm, from the pistol to the 100-ton gun. The term "small arms" includes sporting and military weapons carried by the shooter, instruments fitted for firing a rapid succession of bullets through one or more barrels from a rest are termed "machine guns," while the heavier pieces, used exclusively in war, are denominated "ordnance."

SMALL ARMS

The date and circumstances of the introduction of portable firearms are involved in obscurity. No doubt many attempts were made and failed previously, but gunpowder does not appear to have come into practical use as a rival to the crossbow for the propulsion of bolts or bullets till the reign of Edward III., in 1375 mention is made of men armed with "gornes" at an attack made on a Yorkshire manor-house. The *arquebuse à mèche* was employed in Germany in 1378, and it is therefore probable that some

rough weapon was introduced much earlier. The hand-gun (fig. 1) was used by both infantry and cavalry, it consisted of a simple iron or brass tube with touch hole at the top, fired on a straight stock of wood, when used on foot, the soldier held it firmly by passing the stock under the arm, when used on horseback the stock was shortened to butt against the breast, the barrel resting on a fork secured to the saddle bow. About the beginning of the reign of Henry VII. the hand-gun was improved by the addition of a cock, which was brought down by a trigger to a pan at the side of the barrel, this cock held a match which ignited a priming in the pan, the priming communicating with the charge by a small hole. The next alteration consisted in the introduction of the wheel lock, in which a steel wheel, rasped at the edge, protruded into the priming pan. Into the cock was fitted a piece of sulphuret of iron (pyrites) instead of a match, this was kept down to the priming pan by a spring, another spring, when wound up, acted on the
